During the same period from the time in May when the young shoots are put out by the twenty-four buds on the two canes cc, these shoots have to be most carefully nailed to the wall right and left of the parent wood; and when the flowers are all set the shoots are to have their ends pinched off 1 in. beyond the leaf following the last flower or bunch of Grapes. Laterals or false shoots which push from bases of buds must not be torn off, but shortened with the thumb nail, same as the fruit-bearing shoots, leaving one leaf on, which will do its share of the year's work in ripening the proper juices of the Vine essential to the healthy growth of the wood and roots below. The reader will thus see plainly that the fruiting shoots of the canes cc do not come near each other, but leave plenty of room between for the young canes coming up, which will now give evidence that we are on the right road by their vigour and promise, most of their leaves being 6 in. or 8 in. and some of them 10 in. broad. When the pruning season after the vintage is reached, we prune the Vine very easily by four cuts as follows:—

The spurs of the cane which have borne this year's fruit, with one bud left on each, are in figure 4, "How to do it," shown by ss. Two cuts account for these, and two cut mores serve to prune the young canes DD, leaving on each fifteen or sixteen buds, together thirty or thirty-two, to produce the 15 lbs. of Grapes we confidently expect in the following year. Sometimes we get two bunches out of one bud, and sometimgs a bud fails altogether, but, one with another, we calculate ½ lb. of Grapes to each bud when Clement Hoare's rules are observed. H. M.

May and Late Duke Cherries.—By having trees of each of these varieties on walls on the warmest and coolest aspects, a succession of excellent dessert fruit may be obtained as long as Cherries can be said to be in season. These kinds, too, have another advantage, and that is, they require scarcely any pruning in order to induce fruitfulness, as they form naturally fruit-buds and spurs on the current year's wood, and with a little pinching in summer the winter pruning may be almost entirely dispensed with. As a succession to the supply from walls, these varieties are extremely useful trained as dwarf bush trees, and if well pinched in they may be grown as close together as Currant bushes, and be quite as fruitful. Grown in this way they can be readily protected from spring frosts or the attacks of birds by means of fish nets, which should be securely fixed before the fruit changes colour. The Late Duke is exceptionally late in flowering; some trees of it on a north wall are only just expanding their bloom, while Morellos and other late varieties are in full flower. The black fly is a great drawback to successful Cherry culture; therefore, as soon as it is observed, the points should be dipped in Tobacco water, and in a short time afterwards the whole tree should be well washed with the syringe or garden engine. When grown as a wall tree, the fan system of training Cherries is decidedly the best.—J. H.

House and Window Gardening.

A Graceful Table Plant (Sonchus elegantissimus).—This plant is remarkable for its soft green finely-cut foliage, and extremely graceful habit of growth. As a table plant it is peculiarly interesting, the leaves appearing semi-translucent under artificial light. It is easily cultivated in any warm plant-house or pit, in a compost consisting of turfy loam and leaf-mould in nearly equal proportions, with the addition of a little coarse sandstone grit to keep the whole porous. Several other varieties of Sonchus form very graceful decorative plants, and deserve a place in most gardens where slender-growing foliage plants are desired for dinner-

Sonchus elegantissimus.

table decoration or small vases in the dwelling-room. The plant here figured was sent out a few years ago by Messrs. Henderson & Sons, of the Pine Apple Nursery.

Window Plants.—Those who attempt the culture of plants in windows must bear in mind that success can only be attained by means of patience and perseverance, and that many failures will occur before the necessary amount of experience is gained. Strict attention to cleanliness, care in watering, varying the amount of water given according to the season, the nature and requirements of the subjects grown, and growing only such plants as are suitable to the situation, are the principal points to be kept in view. As a rule, soft-wooded flowering plants do not succeed in the close atmosphere of a constantly heated apartment; they become too much drawn, and consequently fail to attain sufficient vigour of constitution to develop their flowers satisfactorily. Where gas is burnt and a more or less vitiated atmosphere prevails, only plants having foliage of such a character as will allow of its being easily cleansed should be grown. The India-rubber plant, Dracæna congesta, D. rubra, D. Cooperi, D. terminalis, Grevillea robusta, Aspidistra lurida variegata, and such Palms as Corypha australis, Chamærops excelsa, Rhapis flabelliformis, may be maintained in health for a long time if they are carefully sponged with tepid water twice a week. Ferns, such as the Maiden-hair, Asplenium bulbiferum, Platyloma rotundifolia and the Elk's Horn Fern will also thrive if the fronds are well sprinkled now and then. There are also some of the varieties of Selaginellas, such as the Kraussiana and Apoda, which, if covered with a bell-glass, so as to maintain a moist atmosphere around them, will thrive perfectly well, and by their freshness and verdure will be a continued source of pleasure to their owner. In rooms which are kept cool, or where a fire is only occasionally lighted, Geraniums, Fuchsias, Lobelias, and such like free-growing subjects, may be maintained in perfect health. Many hard-wooded plants, such as Cytisus, Coronillas, Azaleas, Camellias, Acacias, &c., will make good growth and flower freely in such situations, provided that due attention be paid to ventilation, and that, after growth is completed, the plants are placed for a time in the open air. Care must, however, at all times be taken not to expose the plants to cutting winds or chilling draughts; neither should they be placed in the open air unless very mild weather prevails. With respect to watering, wait until the soil is dry, and then give enough water to moisten it through. Acacia lopantha, Grevillea robusta, Ficus elastica, and Dracæna conferva, are all of free growth, and would be suitable for the situation mentioned. Keep the Musk in a light situation; admit as much air as possible, placing it in the open air on mild nights.—J. C.

Houseleeks.—I do not think anything has been said about the beauty or utility of our Houseleeks. I have a variety of them planted on a low roof abutting on my garden; they are evergreen and very pretty at any time, but the flowers are most beautiful, and they have the advantage of adorning a place which would be otherwise bare and unsightly. They only need planting in a mixture of cow manure and sandy soil, and will then take care of themselves.—HARTSIDE.

ROSES.

Removal of Suckers.—Constant attention should now be paid to the removal of suckers from Rose stocks. Where the plants have been allowed to remain for a considerable time without removal, these suckers are usually a source of continual annoyance, especially in such stocks as support the weakest-growing varieties of Roses, as in their case the heads of the plants are not sufficient to draw the full quantity of sap which the roots provide; hence the disposition to break out into this underground growth. In the case of stronger-growing varieties, where the heads have been let to attain a large size, there is generally a less inclination to throw up suckers. Even where standard Roses are grown by the sides of walks with their roots under the turf, and where the suckers run underground for a considerable distance before appearing above the surface, it is always the best to trace them right to the base from where they proceed, removing the soil with a planting-trowel or similar inplement, so as to admit of this being done, in which case the operation will be effectual until fresh suckers are formed; whereas, if the shoots are simply broken off at the point where they appear above ground, they keep on repeatedly making fresh growth, which, so far as diverting the strength of the plant from its legitimate course the support of the head, involves a loss little less than if the suckers were not removed at all.

Thinning of the Buds and Removal of Decayed Flowers.—Large Rose flowers, for filling vases, baskets, and the like, are now held in very much greater estimation than they used to be, consequent upon a taste acquired through the large perfect individual blooms that are seen at the exhibitions of Roses; but these large flowers can only be obtained by thinning the buds on the strong shoots, which alone are able to produce such; and where there is a disposition to sacrifice to some extent quantity to quality, the strong shoots should have the buds thinned, particularly where the plants are grown on their own roots and pegged down, under which system the later growths made from the base of the plants are generally very strong and calculated to produce large, fully-developed bloom. To assist the formation of young wood that will give a succession of flowers through the summer and autumn, the first blooms, immediately they decay, should have the seed vessels removed, which will greatly promote second growth.

Manure Water.—In soil where there is any deficiency of enriching elements in the shape of solid manure, either incorporated with it or laid on the surface in the shape of mulching, the ability to produce flowers later on will be very much increased by the application of manure water, which in the case of Roses, as other plants, is much quicker in its effects than through any other means by which manure can be applied. There is no time through the whole spring or summer when it can be used with so much advantage as the present, when there is a conjoint vigorous extension of both roots to absorb and shoots to assimilate it. To Roses on walls it will be especially beneficial, and in their case it can hardly be given in too large quantities. Roses in all positions will bear manure water applied stronger than most plants.

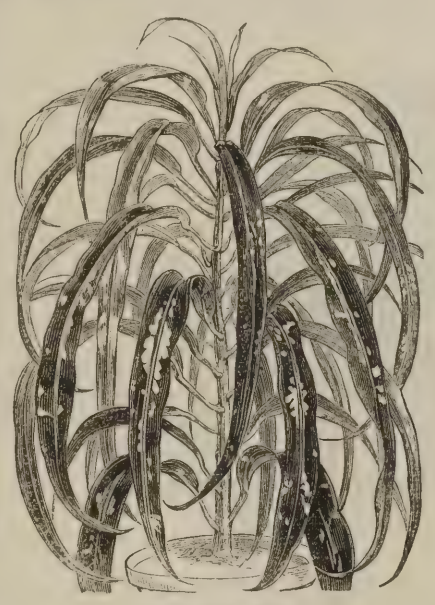
A Prolific Rose.—I have a Maréchal Niel Rose tree, planted two years last autumn in a greenhouse 24 ft. by 8 ft., and trained over the roof like a Vine, from which, since the 19th of March last, I have cut 700 Roses. The tree has made a rapid growth, and appears to be in a very healthy state by the foliage, which is a lovely dark green. The blooms have been very fine and splendidly tinted.—G. Lawrence.

GLASSHOUSES AND FRAMES.

CROTONS AND THEIR CULTIVATION.

Crotons undoubtedly rank amongst the handsomest and most useful of hothouse, or what are called stove plants. They are not difficult to grow, but judicious care is required to bring them to perfection, a condition indicated by good and well-coloured foliage, be the leaves broad or long, according to the variety. They are subject to red spider, and when this pest gets the better of them it destroys their appearance. Much depends, therefore, on keeping them free from spider, while at the same time they should be grown in a tolerably high stove temperature, and fully exposed to the sun—conditions which rather encourage the enemy; but, on the other hand, too much shade spoils the plants by turning the foliage nearly green. Crotons may be propagated by means of cuttings made of the young shoots. These strike readily in a stove temperature, if covered with a bell-glass and plunged in a bed where there is a little bottom heat; but they will strike equally well, though not quite so soon, on a shelf in the stove, if the cutting pot be plunged in another a little larger, and the cavity round the sides be filled up with Moss or soil; one cutting in a 3-in. pot is sufficient. When well-rooted, they should be shifted into a slightly larger size, and the pots should be well drained; but an inch of crocks, or less, will effect this, for it is a bad plan to fill the pot half or quarter full for such subjects merely as a precaution, as some do. Scores of plants are ruined through being over drained in a flower pot. It should never be forgotten that the evaporation from the sides of the pot itself is almost sufficient to dry up a ball of soil in a day, unless the pot is a very large one. The compost which suits the Croton best is one composed of loam and peat in equal quantities, with a good sprinkling of silver or good river sand, and some well-rotted cow-manure; but those who have not these materials may employ without the least hesitation common garden soil, put through a ½-in. sieve, and mixed with fine leaf-mould and sand sufficient to prevent it from binding. If the compost can be squeezed tightly by the hand when moderately moist, without binding like clay or a lump of loam, it will do; or, to be more explicit, as the inexperienced may misapprehend these terms, let the sand and mould be pretty well seen in the compost after mixing—the sand especially, as its presence is more apparent than real, owing to the difficulty of incorporating it with the particles of soil. The same, indeed, may be said of the leaf-mould, which is soon eaten up in a body of loam, and the ball of soil about the roots has quite a different appearance at the end of a year. These remarks apply to all made-up composts generally. Sand should always be freely used when any doubt exists about the compost becoming adhesive eventually. The same kind of compost suits Crotons at all stages.

Young plants may be shifted as often as they require it at any time during the summer, but good-sized plants should have a liberal shift early in spring, sufficient to last them a year, if a continuous and good growth be expected. The plants only begin to make growth in earnest when the roots begin to fill the pot, and a second shift only checks them. The lightest part of the stove is the best place for Crotons, and, in order to have good bushes well furnished to the bottom, the plants should be lifted up clear of their neighbours on inverted pots, to give them light and air all round. As respects their general culture, they need regular and copious waterings—particularly old plants that have been frequently shifted, as the centre of the ball is apt to become too dry, and when that happens, steeping must be resorted to; cleanliness and syringing overhead during fine afternoons, together with a moist atmosphere in the house generally, must also receive attention. Exemption from mealy bug and red spider will depend upon a free use of the syringe and soft water. Hand-washing the leaves of such dense-growing sorts as C. angustifolium is almost out of the question, putting aside the danger of injuring them in the operation; but the brush and hand must be used if the bug gets established among the shoots to any extent; and, if spider be bad, drenching the plants with water in which sulphur has been stirred after being dissolved in milk, will arrest its ravages. A healthy growth, however, promoted by occasional liberal top-dressings, and applications of liquid manure, is the best preventive.



Croton majesticum.

The Croton needs very little training, and staking is out of the question. Nothing looks better than a freely-grown, naturally-shaped bush. It is admissible, however, to tie the branches out for the sake of symmetry, and because they are apt to crowd each other disadvantageously; but more than this is unnecessary. A few pieces of twisted bast run without tight tying from one limb to another, so as not to be seen, will accomplish the object perfectly well. Plants that have grown well during the summer retain their beauty through the winter. It is only necessary to reduce the supply of moisture a little at the root and overhead; but they should not be exposed to a temperature lower than 60°, and if it be kept at from 65° to 70° in mild weather, all the better. Nothing disagrees with them so much as cold, which causes the leaves to drop off, and altogether paralyses their energies for a time. To have good foliage at the end of winter, and to start the plants into growth pretty early in the season, is the way to keep Crotons thickly furnished with leaves, upon which their beauty depends. As regards varieties of Crotons, they are now as plentiful as scarlet Pelargoniums, and as they vary so much in form and colour that to make a selection to suit the taste of the cultivator would be impossible, the best way is for each grower to visit some good nursery, and select for himself. The kind represented by the accompanying woodcut is a very graceful one which we saw a short time ago in Messrs. Carters' nursery.

Annuals for Pot Culture.—Linum coccineum grandiflorum is a very distinct plant, and a useful one in pots through the autumn. The seed of this should be soaked for a day or so before being sown, There are several varieties of dwarf Lupins that make good pot plants, and are very fine and useful for late summer decoration. Two of the best are Lupinus nanus and Lupinus nanus albus. Another grand plant is Martynia fragrans. This is one of the finest annuals grown. In addition to being beautiful in colour, it is very sweet scented and is a fine subject for the conservatory in the autumn. This is a Mexican plant, and one which requires warm treatment all through the growing season. Its seed should be sown early in spring in a brisk heat, and the seed-pan must not be allowed to get dry during the period of germination, otherwise the seeds are apt to dry up after the outer shell has burst. A close warm frame, with full exposure to the sun, will suit this plant through the summer months. Avoid wetting its foliage with the syringe, and water carefully at all seasons. Very liberal drainage must be given, and the soil should be light, rich, and sandy. The plants will require pinching several times through the growing season to keep them dwarf and bushy, and they must be shifted into fresh pots about once a month or six weeks. Very useful-sized plants of this can be grown in 8½-in. pots. Nigella damascena, or Love-in-a-Mist, is another plant that merits attention; when grown in pots it is both striking and effective. Some of the best varieties of Phlox Drummondi are well worth some trouble in order to have them good in pots. They are a useful plant for decoration, and very effective.—R.

Auriculas.—At no season of the year does green fly more persistently congregate on Auriculas than at the present. They cluster about the hearts of the plants and on the undersides of the leaves, and their presence in force is detrimental to the well-being of the plants. A good fumigation with Tobacco smoke is the best and most thorough eradicator—applying it strongly, too, for it will not injure the plants, and following it up with a good brushing by means of an artist's brush. If the plants be looked at daily, and the brush applied for a few minutes, the enemy is soon routed. There is a small green caterpillar also that needs to be sharply looked after. He gets into the heart of a plant, and feeds on the tender leaves, and soon eats away the heart. A good Auricula cultivator makes a constant practice of looking over his plants, and he soon detects if anything is wrong. If, on the other hand, Auriculas are neglected, insiduous foes soon storm the citadel. Auriculas bearing seed are best left in their blooming pots till the harvest is gathered, but as the soil at this time of the year, through frequent waterings, is apt to become sour on the surface, and covered with Moss, it should be frequently stirred. The plants that have been re-potted, if kept cool and shady, will not require much water, and root action goes on merrily in a moderately moist soil. The young stock is now growing fast, and should be shifted into larger pots as required. Over-potting in the case of the Auricula is a great mistake; and especially is this true of small plants, for when overdone with pot room beyond their requirements the plants will decline and die outright. Seedling Auriculas raised from seed sown last autumn, and already pricked off from the seed-pans into store pots will soon require another shift. The largest plants can be placed singly into 2½-in. pots; but it is a saving of time and labour to put three or four plants into 3-in. pots and allow them to flower in them.—D.

Diplacus glutinosus.—This, though an old plant, is not grown so much as it should be, considering how easily cultivated it is and the profuse manner in which it produces its orange Mimulus-like blooms. It is easily propagated by means of cuttings made of the half-ripened shoots taken between April and August, and inserted in sandy soil. When struck, it should be potted off in a compost of good fibry loam, peat, and sand; it may then be placed in a cool frame and kept close until started, when it should have abundance of air. In autumn it should be removed to a greenhouse, where it can be protected from frost. Thus treated, it should bloom well the following spring, and have the coolest end of the conservatory allotted to it,

when it will produce a fine display all summer.—T. W.

Grevillea robusta from Seed.—The elegant Fern-like foliage of this Grevillea gives it an effective appearance in all descriptions of decoration, either for planting out during summer, or for the conservatory, drawing-room, or dinner-table. It is very easily raised from seeds sown in heat; but they should be new, as failures may and do arise from sowing old seeds. Young plants a year old or so are very useful for the purposes just named. I have a number of young plants in 4½-in. pots sown last autumn. A mixture of sandy loam and peat suits them them well: two-thirds of the former to one of the latter is a good proportion.—E. H.

How to Grow Coleus.—One of the main points in Coleus culture is to sow the seed or strike the cuttings early in the season, so that the plants may be in full growth by the commencement of the summer. The easiest way for an amateur who has not the convenience of a stove or propagating house would be to make a mild hotbed about the middle of March. A single load of stable manure would suffice for the purpose, placing on it a small hand-light of some description. Here the seed would germinate freely, or cuttings might be struck successfully. The best method of propagating the Coleus is by means of cuttings; they strike very easily, and make specimens in less time than seedlings. Those who make a point of growing Coleus for summer decoration save a few of the best plants, keeping them during the winter in a warm house. I plunge them in a cold frame without shading; the wood is well ripened by autumn. I then force them about Christmas, and they bloom satisfactorily.—C. S.

Stephanotis floribunda in Small Pots.—Sometimes in spring may be seen in Covent Garden small plants of the Stephanotis in 6-in. pots, bearing several clusters of blossoms, but such are never very plentiful, as the flowers almost fetch as much money as can be got for the plants. Many people have, however, often been surprised to find the Stephanotis flowered in such a small state as it is found here, and have wondered how such results could be attained. The plants are struck from cuttings of half-ripened wood (not points of shoots) in autumn, or are obtained by layering a branch of a plant along a row of pots filled with soil. Such plants, when struck, have generally one joint above the pot, two leaves and two eyes. These eyes produce shoots which are encouraged to grow as much as possible until the middle of summer, when the plants are turned out-of-doors or into a pit or frame in a sunny position, in order to thoroughly ripen the wood. In autumn these shoots are cut back to firm wood, and the plants are placed indoors, when they soon put forth shoots, all of which are sure to produce several clusters of blossoms. These shoots are trained round a few small stakes, and when in bloom the plants are ready for market. Such plants as are not disposed of are served in the way described the next year, when, of course, they make finer specimens. They are

New Coleus.

Where this can be accomplished it is by far the best method, otherwise seed must be relied on. Sow the seed in a compost of sandy leaf-mould and loam, cover it lightly, and cover the pot with a piece of glass until germination takes place. When the seedlings are large enough to handle, pot them off into small pots, shifting them when well established into larger receptacles, employing a compost of leaf-mould, loam, and rotten manure. During the earlier stages of growth ventilate carefully, not exposing the tender seedlings to sudden chills or cold currents of air. but always admitting a little air on favourable occasions. Be careful also never to employ water either for watering or sprinkling which is not of the temperature of the frame. The Coleus is a very free-growing plant, but if once checked seldom starts again freely into growth. By the month of June the heat of the manure will have declined. It will not need renewal, as by economising the sun's rays by shutting up early and covering the frame, the plants will continue to make progress, and may by July be shifted into 4½-in. pots, and be placed in the greenhouse. As regards varieties, there are hundreds, and the other day we saw in Messrs. Carter's nursery, at Forest Hill, a quantity of varieties of a new type which promise to become popular, two of which are shown in our illustrations.

Treatment of Daphnes.—I have grown Daphnes for several years in pots in soil composed of peat, turf, and silver sand; after they have done flowering I pot them on in larger pots, and keep them close till they begin to grow, syringing them every afternoon with tepid water. After they have started growth not allowed much pot room, as in this case they grow too long in the season, and do not ripen their wood so well, but manure water is used as a substitute for more root room just when the plants require it. A mixture of good turfy loam, peat, and a little decomposed manure or leaf-mould, to which has been added a liberal quantity of sand, forms the best compost for the Stephanotis. Good drainage and abundance of water when the plants are in full growth are also essential to the production of fine flowers and the perfect health of the plants.—S.

The True Maiden-hair Fern.—This pretty hardy Fern (Adiantum Capillus-Veneris) grows here on the inside wall on either side of a cool house, and nearly close to the ground, where admired by all who see it. How the plants came to be first fixed there I am unable to say, but I conclude that my predecessor here must have grown plants of it, and that he must have placed them at times beneath the side stages, and that seeds thus became attached to the joints of the brickwork and grew there. That these now increase there can be no doubt, as numbers of minute plants are discernible on the surface of the brickwork. The fronds of Ferns so produced are really charming for bouquets and button-holes, and yet their cultivation is a matter of chance. If the walls of cool houses near the ground were jagged and roughed with mortar, and seeds of this pretty Fern sown upon such surfaces and kept moist no doubt in time the walls would be covered with lovely green foliage that would be ornamental, as well as supplying material for cutting.—E. A., *Middlesex.*

The Blue Cornflower (Centaurea Cyanus minor). — This is, without exception, one of the best and most useful plants that can be grown in pots. I would strongly recommend every one who has not given this plant a trial in pots to do so, as it is sure to give satisfaction. Its colour is the prettiest shade of blue imaginable, and one which will give a finish to a bouquet or a button-hole second to that of no other flower. It is a very free-growing plant, and if sown in succession will flower the year through. I grow it in very rich light soil in 6-in. pots, three or four plants in each. A large sowing of this plant should be made about the middle of June and another in the end of July. The plants should be grown outside during the summer months, taking them under cover about the middle of September, when those earliest sown will be coming finely into flower; and those sown late will succeed them, and furnish a grand lot of choice blue flowers all through the winter months. It is necessary to give them a trifle warmer temperature than that of an ordinary greenhouse.

Ardisia crenulata.—Both the red and white fruited varieties of this plant, when well managed, are amongst the most useful berry-bearing subjects which we have. Where young shoots are obtainable they should now be propagated, putting them separately in small pots, or, if in larger numbers together, taking care that they are so treated that whatever leaves they possess may sustain no injury. For room decoration they are deservedly great favourites, lasting, as they do, with care in good condition for months. If considerable numbers are wanted, it takes some time to get up a stock from cuttings, and beautiful plants may be raised from seed, which if sown now in pots or pans, drained and filled with open sandy soil tolerably compressed, the seeds slightly covered and placed in a brisk growing temperature, after some time the seedlings will make their appearance.—T. B.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

June 7.—Sowing Ne Plus Ultra, British Queen, Fortyfold, and Laxton's Omega Peas; planting out Cardoons; also Wheeler's Imperial and Hartwell Early Marrow Cabbage plants; thinning Onions and giving them a top-dressing of soot; nailing in and tying Roses on walls and washing them well in the evenings with the garden engine to keep down green fly; hoeing off all Raspberry suckers that are not required; clipping Box edgings; sowing American Cress and Chicory; putting in cuttings of Chrysanthemums, Gloxinias, and Pelargoniums; pruning back superfluous wood on wall fruit trees, and nailing in the leading shoots; picking the dead flowers off Azaleas and placing them in greenhouse to make their growth; netting Gooseberry and Currant trees; tying Lettuces.

June 8.—Sowing early Snowball and American Strap-leaf Turnips; putting in cuttings of choice Pelargoniums; pricking off Cinerarias and Primulas; planting out Autumn Self-protecting Brocoli; thinning out Parsley, Spinach, and Turnips; cutting out all small fruit and late blossoms of President and British Queen Strawberries to make sure of fine fruit, and giving them a good soaking of manure water; watering all newly-planted fruit trees; sowing Broad Beans, Coleworts, and Spinach between Currant bushes; also a little Scorzonera; planting Asparagus, Buda Kale, and Couve Tronchuda; thinning Pears on walls that have set too thickly so as to leave two in a bunch.

June 9.—Sowing Broad-leaved Batavian and Green Curled Endive; also Mustard and Cress; potting on Fuchsias, Coleus, and Caladiums; planting out Savoys, double Wallflowers, and Asters; layering Vicomtesse Héricart de Thury and President Strawberries on pieces of turf 4 in. square; potting Cannas intended for conservatory decoration; sowing Larkspurs in pots; planting Pinks, Lily of the Valley, Daisies, Forget-me-Nots, Pansies, Stocks, Asters, and Winter Greens; layering Sir Charles Napier Strawberry; hoeing among Rhubarb crowns, and thinning shoots of Seakale plants; taking up bulbs, and clipping Cerastium tomentosum.

June 10.—Sowing Scarlet Runner Beans to come in for a late crop; potting on seedling Cyclamens, Stocks, and dwarf Asters; planting out Brussels Sprouts, Broccoli, and Celery; giving main crops of Carrots a final thinning, and running the Dutch hoe between them; potting Love-lies-bleeding, Tropæolum, and Verbenas, and staking out and re-potting old plants of Bouvardias that have been cut back; planting a border of Autumn Giant Cauliflower and Cottager's Kale; top-dressing Gardenias with a mixture of peat, loam, horse manure, and silver-sand; layering runners of Black Prince and President Strawberry; giving Seakale and Parsnips a watering with guano water; exposing Peaches that are getting ripe to the full influence of the sun.

June 11.—Sowing Wheeler's Imperial and Hartwell Early Marrow Cabbage to come in for September and October; potting on Balsams, Chrysanthemums, and Heliotropes; planting out Spiræas and Deutzias; planting out Lettuce plants; mulching Peas with rotten manure; Hoeing and weeding amongst all growing crops, and getting the nets put over Cherry trees; potting

shrubby Calceolarias into 10-in. pots; sowing Egyptian Green-flesh Melons, Chicory, more Peas, Radishes, and Spinach; layering Keen's Seedling Strawberries; planting Sweet Peas, Scophularias, Gazanias, and Centaureas in flower garden, and April-sown Lettuces on Celery ridges; thinning and transplanting Parsley; also thinning Onions and Leeks; Sticking Peas; syringing outdoor Peach trees with clear water to keep off insects.

June 12.—Planting Vicomtesse Héricart de Thury Strawberries that have been forced on a south border for autumn crop; also Coleuses, Alternantheras, and other carpet bedding plants; stopping and nailing in the Vines on walls; potting Petunias for conservatory decoration; also Fuchsias, scarlet Pelargoniums, and Heliotropes; planting out a few pot Roses and some April-sown Cauliflower plants, also Ice plants; pricking out Cinerarias and Primulas; putting in Chrysanthemum and Coleus cuttings, and putting greenhouse plants out-of-doors; Earthing-up Potatoes, Melons, and Cucumbers; levelling land for winter greens; going over wall fruit trees and picking off curled leaves infested with insects; thinning Carrots and Turnips, and putting short Grass between Strawberry plants; pegging down plants in flower garden, and watering them; also watering orchard-house trees and late Vineries with manure water.

Glasshouses.

Keep up a succession of Balsams, Cockscombs, dwarf Asters, Mignonette, and others. During all stages of their growth plenty of ventilation must be admitted, and abundance of water given. Than the scarlet Salvia fulgens and the blue S. patens few plants are more beautiful, free-blooming, and satisfactory, either in pots or planted out; they require rich soil and plenty of water, and by cutting off the spent flower-spikes and maintaining a regular supply of young wood they continue in excellent flowering condition until late in the season. Keep shrubby Calceolarias in open houses or frames, and give them plenty of water, but as soon as they come well into bloom remove them to the conservatory. Discard herbaceous Calceolarias when past their best, and if seed be required let it be saved from plants that have borne the finest-formed and best-marked flowers; place them in a cool or light house, and supply them moderately with water. Any suckers of Cinerarias ready for potting should now be removed from the old stock, potted singly in moderately rich soil in 2½-in. or 3-in. pots, and put for a time in cold frames, placed so as to face the north.

Pelargoniums.—Some autumn-struck cuttings of scarlet and pink Pelargoniums should now be potted for winter flowering. Amongst the single red varieties nothing is better than Vesuvius, nor in single pinks the old sort Christine; both are short-jointed, compact growers, producing their flowers freely through the winter with a little warmth.

Heliotropes.—Some spring-struck cuttings of these favourite plants should now be moved into 6-in. or 7-in. pots, plunged outside, kept stopped, and the flowers picked off similarly to the Pelargonium. This sweet-scented favourite so managed will produce flowers, with the assistance of a little warmth, all through the autumn up to the end of the year.

Lilies in pots will now require more water as the soil gets full of roots, and should be placed in an open situation away from the influence of walls or trees to avoid weak and spindly growth; turn the pots round every two or three weeks to prevent the plants getting drawn to one side. The earlier-flowering kinds, such as L. eximium, will now be benefited by the application of manure water. See that all are kept perfectly free from aphides, which get down into the points of the shoots on the partially-developed leaves, and in a very short time cause them to become curled and permanently injured. A little Tobacco water syringed into the points of the affected shoots and on the under sides of the leaves will be found effectual in destroying them. The plants will be much better for being plunged in ashes, which will save labour by their requiring considerably less water, and greatly benefit them by preventing their thick mass of roots from being affected by the sun. The earliest flowered kinds should be staked and tied, so far as they require it, before the growth gets too far advanced.

Deutzias in pots that were forced in the winter, and have been since kept in a Vinery or other structure where a little warmth could be added, will now have so far completed their growth as to be ready for turning out-of-doors. This is one of the few hardy plants that make its growth for next year's flowering much better when kept inside than in the open air. A good companion to the above is the double-flowering Plum. These should also be plunged during summer.

Chrysanthemums that were moved a short time ago into their flowering pots should now be plunged. It often happens that a few of the strongest shoots of these so far take the lead as to deprive the weak ones of their share of nutriment. Where this is the case pinch out the points and peg them out horizontally to the sides of the pots.

Petunias and Balsams.—Petunias struck late should also be potted, tying them well out, and stopping the shoots to keep them bushy. Many of the double varieties now in cultivation possess a compact habit of growth, and, from their easy culture and free continuous blooming disposition, they are very useful for greenhouse decoration during the summer and autumn. Earlier plants of these Petunias that have been flowering some time should be assisted with manure water and kept tied into shape, by which means they will continue blooming for some time yet. The later-sown Balsams should be moved out of the small pots they occupy into others 7 in. or 8 in. in diameter. Those quick-growing, gross-feeding plants require a rich soil, a light position, and a plentiful supply of water to produce them in anything like condition.

Flower Borders.

Numbers of plants will now require supporting by sticks and ties. This should always be carried out as soon as it is needed, or the plants get broken down and disfigured by the wind. Never use more supports than are absolutely necessary, and keep them as much out of sight as possible. Get the seed of herbaceous plants sown in good time, by which means they get strong before winter, instead of struggling for existence through the dry late summer months, requiring much more nursing than if they had attained more strength early in the season. Polyanthuses, Delphiniums, Sweet Williams, Aquilegias, with a host of similar kinds, if sown at once, will make plants by the autumn superior in quality to what they would be if the sowing is longer deferred. Sow on a well-prepared piece of ground, with the surface made quite smooth, and cover the seeds lightly with finely-sifted vegetable mould; if the situation be a little shaded from the midday sun, so much the better.

Fruit.

Now that all danger from frost has passed, pinch or cut off all superfluous growth from Pears, Plums, and Cherries, and apply remedies for the destruction and prevention of insects and blight of all kinds. Cordons and espaliers of Apples and Pears should now have the fruit thinned and the leaders tied to supports. Strawberry runners, whether intended for forcing or planting out, should be layered as soon as the young plants are formed. For the former purpose early runners are essentially necessary, that a long season may be had for the full development and ripening of the crowns, without which it is useless to expect successful results. Blackbirds and thrushes attack the fruit as soon as, and sometimes before, they change colour; and it is advisable, therefore, to protect it with netting as soon as it begins to turn. Water effectually when necesary.

Raspberries.—In order to concentrate the energies of the plants in the production of the present season's fruit and the growth of next year's bearing wood, the young shoots that spring up from the bottom should now be thinned to within something near the required quantity. In the case of young plantations that have not yet attained their strength, two or three bearing shoots will be enough; those that are stronger may have six. In thinning the young shoots it is not sufficient to cut or break them off level with the ground; for if so treated they will quickly spring again. An ordinary planting trowel will be found the best implement to use for the purpose, removing 1 in. or 2 in. of the soil, whereby the shoots can be taken off directly from where they spring, in all cases retaining the strongest. The ground amongst these, as well as Gooseberries and Currants, should be again hoed over. If this be attended to sufficiently, often the weeds can be effectually kept down with comparatively little labour.

Vegetables.

The main crop of Celery should now be planted, choosing showery weather for this operation should such occur within reasonable time, as when the ground is moist and the weather dull the roots lay hold of the new soil more quickly than they could be induced to do by artificial watering. The last sowing of Peas may now be made where these are required as late as they can be had; but, unless in open favourable situations, the produce of such late sowings is precarious. Give them plenty of room by sowing thinly and having the rows placed far apart. Where Broad Beans grow strongly when they come into flower they will be benefited by having their tops nipped off. This has the effect of concentrating the efforts of the plants to form pods instead of making useless growth.

New Coleus.

Winter and spring Broccoli should now be planted, and if the plants have been treated as advised some time ago, they will now be fit for putting out. In order to impart to the Broccoli that hardy condition of growth which is indispensable to its standing a severe winter, it should be planted widely apart; if planted too close, it is certain to be weak and soft, and almost sure to succumb on the first occurrence of severe weather. If the land on which it is to be grown is of average quality and fairly manured, the plants should stand 3 ft. apart each way. Where ground is limited, this may seem extravagant, but it is false economy to run the chance of losing the greater portion of the crop through an attempt to grow more than the space at command will permit. On poor inferior soils, where the plants will not attain full size, they may stand 2½ft. apart

The White Everlasting Pea.—This fine old plant is not nearly so much planted as the coloured form, though the white one is really the better plant of the two. It grows as freely as the old form, often attaining 8 ft. or 9 ft. in height, and it is, when in flower, a mass of snowy blossoms. The flowers, being borne on long slender stalks, are well adapted for cutting, and they may be used along with the choicest exotics. When once planted in good loam it grows like a weed.—W.

Antirrhinums.—Plants of these from early sown seed put out now will bloom in August and September, and succeed the plants raised from seed in August last. In this way the pretty homely Snap-dragon can be had in bloom throughout a good part of the summer. A good strain only should be grown, as it is a waste of time to cultivate inferior forms; and now that a preponderance of striped flowers is certain to occur in a good strain, that is an additional reason for having a plantation in a garden. Cold wet springs have an injurious effect on old plants grown in a cold wet soil. On the other hand, plants in a light drier soil do wonderfully well; and really very fine specimens can often be seen in gardens in full bloom. Those who have a wet, cold, uncongenial soil will do best to raise plants in the autumn, winter them in store boxes in cold frames, and plant them out in March and April, when the weather is favourable.—N.

Spotted Mimulus.—The grand spotted Mimuli are fine plants with which to cover a north border during the summer months. During hot weather, in the south at least, they are unable to bear strong sunshine; but farther north, no doubt, they would do well in the sunshine, if not exposed to sweeping winds. No plants that will grow freely in the open air give such grand hues of colour and such superb markings as do these spotted Mimuli. Many of the flowers are 2 in. in diameter, and are richly coloured beyond the power of the artist to depict. I have them here growing on the north side of a cowhouse, blooming most abundantly, and little affected by the winds and heavy rains. If a few of the blooms fall, others come out at once and take their places, so that flowers are never wanting. The best results are obtained when seed is sown, and grown on for a short time in a gentle heat. Soon the seedlings require to be pricked out into pans or boxes, and from these they should in a few weeks again be placed into large 3-in. pots. As soon as the plants are strong enough, the point of the main or leading growth should be pinched out, and then the shoots that start out from the base of the plant will all come up together. In this way, if the plants be turned out some 10 in. apart, they will grow into an even mass and make a grand display of flower. The soil should be light and free, and a top-dressing of Cocoa-fibre refuse aids to keep the surface cool and clean. The great variety in the colours and markings adds greatly to the interest attached to their culture.—D.

A FEW HARDY MARKET PLANTS.

CLOVE CARNATIONS are sold in the form of roots, and at times are in considerable demand. These, and the better kinds of Carnation and Picotees, are, as is well known, propagated by layering the side shoots and planting them out in raised beds when rooted. They are very liable to be attacked by wireworms, which are very destructive to them. A plentiful dressing of lime and soot when digging the ground is found to be useful in keeping them in check. Using fresh land which has been well and deeply dug and exposed to the frost during the winter as much as possible is an excellent mode of securing a healthy and vigorous stock of Pinks and Carnations. These flowers are also cut and sold in very large quantities in bunches consisting of a dozen each.

Sweet Williams raised from seed of a good coloured strain are also popular, and require to be treated like Pinks. Pansies propagated by seed, cuttings, and division of the roots also meet with a ready sale. They thrive best on moderately rich heavy land, and if the position is cool and shady, so much the better. They are sold in small boxes, in which the roots are packed in Moss. They are taken up when they have one or two expanded flowers on them. Polyanthuses from seed and division of the roots, and otherwise treated as Daisies, are charming plants and universal favourites, as are also Hepaticas, which always find admirers. The Ranunculus and Anemone are likewise both favourite market subjects, and in some seasons their blooms in a cut state are very profitable. Few more pleasant sights can be seen than a good bed of Ranunculuses or Anemones in full flower; the quantity of blossom produced and the variety of the colouring in good strains are quite remarkable.

Wallflowers of a good dark colour, dwarf, and early blooming, are very largely grown, both for sale in the form of roots and also in the shape of cut bloom. Immense quantities of the latter are sold tied up in good-sized bunches. It is no uncommon thing to see them brought into Covent Garden by the cartload during the height of the blooming season. Of course when produced in such abundance the price is extremely small; but, generally speaking, Wallflowers are a fairly remunerative crop. They will thrive well under fruit trees, a position in which but few things would be grown to equal advantage.

Double Convolvulus.—This is an excellent climbing hardy plant, which produces in summer and autumn large rose-coloured double blossoms. It likes a light rich soil and warm aspect. It may be grown in large pots, tubs or boxes for forming small bowers or balconies, &c., or it

Double Convolvulus (Calystegia pubescens).

may be grown to hide small fences, or to climb round posts or stems of trees. It may be had at any hardy plant nursery, and it is easily increased by division of the root, which runs rapidly. Its botanical name is Calystegia pubescens, flora plena.

Chrysanthemum segetum (Corn Marigold).—I saw a plant of this in a greenhouse a few weeks ago, which had been taken from a Corn-field last summer. It was about 2½ ft. high, and was profusely covered with large, soft, orange-yellow flowers, nearly twice as large as the field type. It seems a desirable plant to grow along with the white Paris Daisy (Chrysanthemum frutescens), and would probably flower well in the early spring, and continue in bloom a long time.—JOHANNES.

Ranunculus in Pots.—Those whose love of this flower would lead them to desire it as an ornament in the dwelling-house may grow a few in pots. The strong-growing sorts will in this way produce fine blossoms, though not in general fit for exhibition. Plant two or three roots in a 7-in. pot, in such soil as is directed for sowing seed. If early flowers are wanted, plant in October, and plunge in ashes or sawdust in a cold frame; if otherwise, plant in February, and plunge the pots to the rim in a warm border. Shortly before flowering, the pots may be taken up, cleaned, and placed in a situation sheltered from the mid-day sun.—C. T.

Pæonies.—These are now growing strongly, and should have every encouragement, Towards the middle of the month the flowers will be expanding, and as they invariably do so at a critical time when frosts may be looked for, a little protection should be given where possible. Some cultivators adopt the practice of syringing just before the sun gets on the flowers.

The Dark-spotted Poppy (Papaver umbrosum).—This is a brilliant hardy annual, and one that, when in flower, never fails to catch the eye, even at a considerable distance off. It grows about 2 ft. high, and has a habit like the common field Poppy. The colour of the flowers is a dazzling scarelt, with a jet-black blotch on the inner base of each petal, which is sometimes margined with ashy-grey. The black blotch is conspicuous also on the outer face of the petals, thereby rendering masses of the plant a grand sight. It flowers in early summer after Anemone fulgens is over. It is hardy in this country. Though an annual, it is best to sow its seeds in autumn, so as to ensure strong plants for flowering the following summer.

ANSWERS TO QUERIES.

2216.—**Roses not Flowering.**—We should suppose that the plants in question are either deficient in vigour, or that they have not been properly treated during the growing season. If the following instructions are followed a plentiful show of bloom should be the result next spring:—Place the plants at once in a sheltered position in the open air for abont a fortnight, at the expiration of which time plunge the pots quite to the rims in the soil in an open sunny situation. Mulch the surface of the soil with manure and water freely in hot weather. In the autumn, as soon as the foliage is decayed, replace the plants in the house, cutting out all very weakly growth and pruning back the strongest shoots to two eyes. If the plants are in small pots, and are root-bound, shift them into the next sized pot. Any which may not appear to need re-potting should receive a top-dressing of some concentrated manure. Give plenty of air during the growing season, but avoid cold draughts; and if green fly appear, dust with Pooley's Tobacco Powder.—J. C. B.

2219.—**Growing Dates.**—It is customary even in the case of such Palms as succeed in a cool house to bring them along in their earlier stages of growth in a close warm atmosphere, plunging the pots in bottom heat of some kind. Not only do the plants sooner attain large proportions, but they present a much more healthy appearance when thus treated than when subjected to a low temperature. The Date Palm forms no exception to this rule, and the young seedlings will require a long period to render them useful for decorative purposes unless pushed along in heat. They should now be potted separately in small pots in a compost of well-sanded fibrous peat. Place them in a warm corner of the greenhouse under a hand-light, and shade from bright sunshine.—C.

2053.—**Climbers for Planting out in cool Conservatory.**—Passiflora Newmanni has long blue flowers, is evergreen, and should be accorded a light airy situation. Tecoma jasminoides possesses beautiful bell-shaped blooms, white with dark spots, not so large but almost equal in purity to a Gloxinia. This is a very strong grower, running up, when in the enjoyment of a free root run, some 50 ft. in height. When planted in a house of moderate dimensions, the roots should be confined to a limited area, which will also have the effect of inducing it to flower more freely. This plant will succeed on the shady side, but is more satisfactory when exposed to the full light. The Passiflora is also a free-growing subject, and may be so planted that the roots are in an outside border, as may also Berberidopsis corallina and Jasminum gracile, both of moderate growth, the former with red, the latter with white flowers. Physianthus albidus—an evergreen twiner, with white flowers—should be placed in the warmest end of the structure. Celastrus scandens is deciduous, has greenish fragrant flowers, and runs up some 15 ft. in height.—C.

2217.—**Grubs in Potato Land.**—The grubs are the larva of the cockchafer, and they remain four years in the larva state, feeding upon the roots of plants. The only way to get rid of them is to pick them them out carefully when working the land, and to turn it over with

the fork or spade as often as possible before planting the crop. When a plant appears to flag, if the earth round the stem were removed, probably a grub would be found there. As every female cockchafer lays about eighty eggs, something might be done to reduce their numbers by destroying them before the eggs are deposited in the earth. Poultry and rooks should be encouraged where these insects are numerous.—H.

2220.—**Succession of Flowers for Window Boxes.**—It is not stated if the boxes are placed inside or outside the windows, but I will assume they are outside. For spring—Primroses, including the whole family, Tulips, Daisies, Lily of the Valley, Scilla sibirica, Dielytra spectabils, Hoteia japonica, Hyacinths, Iberis coreacea, Summer—Mignonette, Harrison's Musk, Stocks, Pelargoniums (including the spotted show kinds, the zonal, scented foliage, and Ivy-leaved varieties), tuberous Begonias, Tropæolum Fireball, Chrysanthemum frutescens, and the yellow variety. Autumn—Chrysanthemums, Asters, Japanese Anemones, Sedum spectabile, Veronica Imperial Blue, Colchicums. Winter—Laurustines, Pansies and Violets, Christmas Roses, Winter Aconites, Snowdrops, Crocus, Creeping Jenny, Yucca filamentosa. A few shrubs would add to and eke out the display in winter. Some of the Aucubas and Euonymuses, Ivies, and small growing Conifers, such as Retinospera plumosa, and obtusa, will be desirable.—E. A.

2255.—**Prickly Comfrey.**—Plant the sets in rows 2 ft. apart, and about 18 in. from plant to plant in the row. March is the best time to plant, and the land should have been well manured and cultivated previously, as the Prickly Comfrey will occupy the land many years, and though it would yield heavy crops on poor land, yet it does best with liberal treatment. It is not easy to speak with any exactitude as to the number of plants that will be required to supply a horse and pony, so much depends upon the nature of the soil, &c., but a quarter of an acre will yield successional cuttings from April to October, and might perhaps be sufficient to begin with.—E.

2228.—**Adiantum Farleyense.**—Pot in rough turfy loam, and grow in a light house without much shade. The pots must be well drained, as this, like all Ferns, requires a good deal of moisture. Increase by dividing the roots, but under greenhouse treatment this should not be resorted to often, as it takes some time to establish the young plants. I should prefer the cool greenhouse to the warm room, as Adiantums will not long thrive in a dry atmosphere. All potting should be done early in the season, so that the pots may be full of roots before the short days come.—E.

2262.—**Uses of a Cellar.**—In active horticulture there are not many uses to which a cellar can be put; and it is doubtful whether there are other uses in the direction indicated and beyond Mushrooms, than the blanching of Seakale, Rhubarb, and Asparagus in the early spring, or Endive in the autumn and winter. As to the growth of plants, light is essential, and it follows that plant life cannot exist where there is neither light nor pure air. One of the best uses to which to put an airy cellar is to make of it during the winter months a store for Apples, Pear, Nuts, Onions, Potatoes, and other tuberous roots. All these should keep well in such a place if the cellar be dry. Where the inhabitants are not very particular as to perfumes, cellars have been utilised as places for the keeping of rabbits, fowls, and even pigs; but these are not horticultural uses, and if they were we would not recommend them.—D.

2248.—**Pansies Deteriorating.**—Four distinct questions packed into one needs deliberation, because the later ones render us almost oblivious of the tenor of the first; but we will deal with them seriatim. Pansies as a rule do not deteriorate, neither can they be said to be deteriorating, or to have deteriorated. So far from that being the case, the Pansy is finer than ever it was, as all our best growers can practically show. When the querist asks if a Pansy will deteriorate, he probably means that, as the plant's flowering season advances, its blooms become smaller; but that is not deterioration, as, when the proper season arrives, the plant, having renewed growth, will be as good as ever it was. Now it may be accepted as a fact that the first blooms from a hardy plant are always the finest; and even though the earliest blooms be all pinched off it, yet the later ones will still be smaller than those first expanded. If the spring shoots be cut away from a Pansy plant for the purpose of saving the strength for the production of bloom later in the year from young growth, yet the blooms so produced will not be so fine as would have been the flowers on the spring wood, except the new growth produce blooms in the cool autumn, when the flowers may be fine. Divided Pansies will produce as fine blooms in the spring as old plants or cutting-struck plants will; but it must be remembered that the spring is the best season of the Pansy, and then its blooms are always the finest. Cuttings from any good Pansy or laced Pink will reproduce for the time even finer flowers than did the old plants, but will not bring laced Pink flowers if those on the parent plant were not laced. If they were, then the lacing will be as good, and, for a time, better.—A. D.

2266.—**Fowls' Manure.**—When horses are fed entirely upon corn and fowls are the same, the relative strength of the manure from each is about the same, assuming that both are droppings only, and not composed largely of litter. Horse manure, however, at any stage is by far the most tractable, and, perhaps, the most useful. Fowls' manure is useful to employ raw as a dressing when raked from off a loose floor of ashes or road dust. In such case it may be distributed over the soil in about the same ratio as would be horse manure from the highroad. It may be used fresh for the making of liquid manure, and when so employed should be put into any coarse bag, and so sunk into the receptacle, the water being allowed to stand for several days before using. It may be then given to Onions and other plants, with due moderation.—D.

2261.—**Watercresses.**—The profit to be made from the growth of Watercresses depends largely upon the nearness to a good market and method of culture. If facilities for sale are easy and the Cresses are well grown, then running water should be made to pay through their means. But profits depend upon so many things, that statements are unreliable, although they have been put at £50 per acre yearly. It is essential that, however slowly, there should be at least some regular movement of the water; that it shall be shallow, and always about the same depth. If any diversion of a stream can secure these things, then an excellent foundation for a Watercress bed is laid. It is well to remember in doing this that others below may have some rights over a stream also, that may be affected by the proposed use. A small engine is the best means of getting water forced back again, but whether the game is worth the candle is indeed doubtful.—D.

2195.—**The Best Roses.**—This is, to a great extent a matter of opinion, as growers differ considerably as to the merits of this or that Rose. The best exhibition Roses were settled by vote of all the leading nurserymen and amateurs in 1878; and the first six on the list of seventy-two are as follows:—Marie Beaumann, Charles Lefebvre, La France, Baroness Rothschild, Louis Van Houtte, and Etienne Levet. These are all truly grand sorts, but for garden purposes no doubt others would be found more suitable. I would recommend John Hopper, Alfred Colomb, Madame Victor Verdier, Dr. Andry, Mons. E. Y. Teas, Sénateur Vaisse, Gloire de Dijon, Marquise de Castellane, &c.—William Walters, *Burton-on-Trent.*

2249.—**Manure for Plants.**—Pig manure is perhaps of all animal manures the most unfitted for pot plants. It is rank, full of the germs of insects, and suited only as a dressing for light dry soils, and for gross-growing plants. Probably if thrown into a heap and turned occasionally for a year, it might become suitable for potting, but not nearly so valuable as horse or cow manure when well decomposed. Probably it would best assist to purify the pig manure if it were mixed with an equal portion of dry loam, and kept frequently turned to admit air, and thus sweeten it. Excepting sweet horse droppings we know of no animal manure that can be safely used fresh with pot plants.—D.

The Dark-spotted Poppy (Papaver umbrosum.

2061.—**Spigelia marylandica.**—In its native country this plant grows in sheltered situations, the roots finding their way deep down into a body of rich vegetable mould. Shelter from cutting winds, a free root-run in congenial soil, partial shade in summer, with abundance of moisture in hot weather, are the essential points in the culture of this beautiful but somewhat rare plant. A position in which the natural conditions can be imitated should be chosen; and where the soil is not of the right description, it should be taken out 2 ft. in depth and filled up with a well-sanded mixture of loam, leaf-mould, and peat.—J. C. B.

2260.—**Wallflowers not Blooming.**—July is too late a period of the year in which to sow Wallflowers. Like Sweet Williams, Canterbury Bells, &c., they are true biennials, and if

not sown as early as May will rarely bloom the next year. All about London, where the Wallflower is grown to an extent of which provincials have little knowledge, seed is invariably sown in the months of January and February to secure bloom as early as possible. March and April are good average months, but late enough to enable large robust plants to be obtained. Perhaps yours is a particularly late locality. To residents in Middlesex it gives surprise to read that plants were kept in a frame during the winter, as here many hundreds of acres are grown in the open ground, and the plants rarely suffer. Another year sow earlier, and thus avoid your present difficulty.—D.

Narcissus poeticus Failing.—The cause of the Narcissus buds withering before expanding probably arises from the plants being too dry at the roots. Those that have not thrown up flower buds have doubtless had the foliage injured the previous year, either by being cut or by damaging the roots by digging, or by not having sufficient moisture in the ground; perhaps from being planted under overhanging branches of trees or too nea buildings. If these evils are guarded against, the plants cannot fail to flower; but they probably will require a year or more to recover strength. If the soil is naturally very dry, take them up about the 20th June, or sooner if the foliage becomes yellow at the extremities; divide and plant them 3 ft. apart, in clumps, in the shade of some low-growing shrub, or in some other moist situation; but in either case quite open to the sky. Don't dig near them, as that only hastens evaporation. —T. B.

Fennel Roots.—It is not the roots that are eaten in Italy, but the lower end of the leaf stalk, at its junction with the roots, and which, to an inexperienced eye, may be mistaken for bulbs. The plant appears to be raised from seed planted out in rich soil, and in the autumn earthed up 3 in. or 4 in. only to blanch it. It is boiled and served with white or brown sauce in the same way as Celery, and is palatable enough, but not equal to it.—T. B.

2133.—**Spotted Geranium Leaves.**—The roots are probably in a bad state. Turn the plant out of the pot, and examine the drainage. Should this appear defective, and the roots discoloured, work away some of the old soil from them, and replace the plant in a clean pot of the same size, working in a little fresh well-sanded soil between the ball of old soil and the pot. Water carefully, and place in a sunny airy situation.—C.

2204.—**Summer Flowering Bulbs.**—Some of the late-flowering Scillas, such as peruviana, ciliaris, japonica, and autumnalis, might succeed in the situation mentioned. As a rule, however, such bulbous-rooted plants as bloom in the summer and autumn months require a free circulation of air around them.—C.

2222.—**Growing the Cocoa-nut.**—The Cocoa-nut requires a brisk bottom-heat of 70° to start it into growth, growing freely in a moist atmosphere of 70° by day, and 60° to 65° by night, with a minimum winter temperature of 55°.—C.

2157.—**Muscat Grapes Spotting.**—*C. W.*—I am told that this is caused by the rays of the west sun falling on the Grapes after the house is shut up. The best preventive is shading with whitewash or tiffany early in the season.—G. B.

2192.—**Disease in Gooseberry Trees.**—The yellow spots are in all probability a fungoid disease prevalent in some seasons, and for which we have never found an effectual remedy. Syringing with soft soap and black sulphur will check its ravages, but the remedy must be applied directly the disease appears. When once thoroughly established it is almost impossible to eradicate it.—J.

2226.—**Books on Tobacco Culture.**—1, "Le Tabac: sa culture"; Grandeau et Schlœsing (1 fr. 25 c.), Librairie Agricole, 26, Rue Jacob, Paris. 2, "Tobacco Culture," (a pamphlet); New York, 1863; Reports from fourteen different growers in various States of North America. 3, "Tobacco; how it is Raised and Prepared" (a pamphlet): Richmond, Virginia, 1873. I do not know the publishers of the last two, but this can be ascertained at the British Museum.—OMBU.

2276.—**Fruit Trees for North Walls.**—What are the best fruit trees to plant against a north and north-east wall?—AN AMATEUR GARDENER. [Morello Cherries, Currants, and Gooseberries. Victoria Plums sometimes do well on north walls.]

2277.—**Cayenne Pepper on Flower Beds.**—Will cayenne pepper put on flower beds to keep cats off do any injury to the plants?—W. DULIEU. [We should think not; but if you were to give a plant or two that you do not care about a good coat of pepper you would find out for yourself.]

2278.—**Potting and Planting Annuals.**—I have a crop of Asters, Chrysanthemums, Mignonette, and Godetias, coming up now. I want to know at what size I should pot them, size of pots, and if more than one plant should be put in each pot. Also, what distance apart should they be in the open ground?—P. M. C. [Mignonette will not bear transplanting very well. It should be sown in pots or in the open ground where it is to remain—thinning out the plants to 3 in. or 4 in. apart. Asters may be put four or five in a 6-in. pot, or be 6 in. apart in the open ground; Chrysanthemums about the same; and Godetias may be put a little thicker.]

2279.—**Plunging Bedding Plants.**—I am anxious to know whether in bedding out Geraniums and other bedding plants they will not answer as well plunged in their pots as when taken out of them?—IGNORAMUS. [They will not grow so freely, but they will flower more profusely.]

2280.—**Wax Plant** (Hoya carnosa).—How can I revive a Wax plant which appears to be dying?—SUBSCRIBER, *Bristol*. [Judging from the leaf sent, the plant appears to have been over-watered. We would advise you to let it get quite dry; then cut it back considerably, and place it in a warm moist temperature, giving it very little water at the root. It may then start afresh, when the old soil should be removed from its roots, and the plant be re-potted in turfy loam or peat, with some finely-broken crocks or old mortar added; also some very coarse river sand.]

2281.—**Crinum capense.**—Should the above be planted wholly underground like Narcissus and Hyacinths, or only partially so, like Amaryllis?—W. D. P. [Just cover the top of the bulb.]

2282.—**Treatment of Alstrœmerias.**—Can any reader inform me what is the most suitable soil, aspects, &c., for Alstrœmerias?—G. S. M. [Deep sandy soil, and in any warm aspect not too much exposed.]

2283.—**Thinning Radishes and Lettuces.**—My Radishes and Lettuces are coming up too thickly. Ought they to be thinned? and will they grow if divided?—A BEGINNER. [The Lettuces may be thinned and transplanted, but Radishes are not worth transplanting even if they would succeed. Throw the thinnings away.]

2284.—**Transplanting Sweet Peas.**—I have some Sweet Peas about 1 in. above the ground. Can they be transplanted? or, if moved, will they die?—A BEGINNER. [Sweet Peas may be transplanted with every prospect of their succeeding. Choose a showery day for the operation if possible.]

Soil for Palms.—*Old Subscriber.*—Turfy loam and peat in equal parts with a few pieces of charcoal about the size of nuts, with the addition of a liberal quantity of coarse silver sand, will grow Palms well. When the pots are full of roots liquid manure, or some good artificial manure, may be given with advantage.

Soil for Alocasias.—*Old Subscriber.*—Lumpy peat, coarse silver sand, and plenty of pounded flower-pots or bricks. Turfy loam may be used instead of or in addition to the peat, if more convenient to get.

2285.—**Fruit for Exhibition**—Can you tell me how to grow fruit for exhibition?—D. [Probably we can, if you will tell us what you want to grow.]

Paraffin in Water for Plants.—*D.*—A small quantity of paraffin spilled into a well will not affect the water to render it injurious to plants.

Insects on Pyrethrum.—*Harry.*—The insects enveloped in white foam are what are generally known in country places as the cuckoo-spit. You can easily get rid of them by washing or syringing the plants frequently with clean water.

Unhealthy Roses.—*R. H. H.*—The leaves sent are shrivelled up. Well tread the soil round their roots, and give a top-dressing of rotten manure; also a good watering occasionally. The soil is too light and dry for Roses probably. Also read last week's GARDENING.

Cucumbers Without Heat.—*W. C. P.*—Cucumbers may be grown successfully from June till September in a house or frame without the aid of any artificial heat whatever.

Cucumbers from Cuttings.—*W. C. P.*—Take off short-jointed shoots having a growing point. Cut off with a sharp knife immediately below the joint, and insert in small pots of sandy soil. Place under a bell-glass or hand-light in a warm pit or house, and if kept in a moist condition they will root in a few days. If a leaf can be left close to the joint all the better.

Renovating an Asparagus Bed.—How can I do this?—*Subscriber, Bristol.*—[You may improve the bed by cutting out all weak growths, letting only the strongest remain; then cover the bed with a few inches of good rotten stable manure, and give a liberal supply of manure. Water through the summer. But your true course is to make a new plantation.]

Cyclamen and Primulas.—*Inquisitive.*—Strong seedling Cyclamens, potted on now and grown in a close frame during summer, should make fairly good flowering plants by February next. They will require a dry airy house in autumn and winter to prevent them damping. Primulas many be grown in the same way. You will find plenty of information on the culture of both plants in back numbers of GARDENING.

Insects in Cucumber Frame.—*A. B. A.*—The insects sent came out of the manure; they will not do much harm to the plants. A little Tobacco powder or Scotch snuff would probably disperse them.

Gourds and Marrows not Growing.—*Cordwainer.*—You should sow some more seed at once, or purchase some strong plants. There is plenty of heat in the frame you mention to give them a start.

Arum Lilies and Cyclamen.—*L. L.*—These may be grown in an unheated house with a fair amount of success. Procure at once some young plants of the Arum from any good nursery, and plant them out in a bed or border of rich soil, and keep them well supplied with water. In autumn lift and pot them, and place them in your greenhouse; they will flower in spring. They may be grown all summer in pots if you cannot plant them out. Cyclamen may be treated the same way, if you procure bulbs at once.

Daisies on Lawns.—*Havelock.*—There is no need to cut the roots in half when you renovate your lawn. Every root can be dug completely up, and if you use good Grass seed you will not have many Daisies.

Rock Strawberry.—*E. J. M.*—This ought to be obtainable at any good hardy plant nursery. Mr. Smith's nursery, St. John's, Worcester, is probably the nearest one to you.

Dielytra after Flowering.—*Flores et Flores.*—If you cannot plant it out, remove some of the loose soil from its roots, and pot it in a larger pot, using rich sandy soil. Place it in a half-shady situation, and keep it well supplied with water till the foliage shows signs of dying off, when less water will be needed.

Cultivation of Pansies.—*W. A.*—A long article on this subject was given in GARDENING, May 15. We know of no book on the subject you mention.

Washing Pots.—*A. N. B.*—We would not advise you to place pots containing plants in strong soda-water whilst washing them. If you place the pot on the edge of a bench, and place your bucket of soda-water underneath it, you can then, with a stiff brush, cleanse the pot without allowing the water to get into the soil.

Capsicums.—*H. P. K.*—See GARDENING, February 28, of this year.

Chrysanthemum frutescens Etoile d'Or.—*Meadowcroft, and others.*—Mr. Howard, Nurseryman and Florist, Southgate, London, N.

Apple Trees not Growing.—*A. N. B*—If the trees show no signs of life, we would root them out, and use the wall for some other purpose till autumn; then plant fresh trees.

Double Seedling Daisy.—*Subscriber* (*Aberdeen*).—The Daisy sent is an excellent one, and appears to be grown in a manner we seldom see Daisies about London.

Mushroom Growing.—*J. S.*—Fowls' manure is of no use for this purpose.

Sternbergia lutea.—Is this hardy?—F. A. S. [Perfectly.]

Dick.—At any good seed shop, in tins or bags.

Names of Plants—*H. L. F. G.*—Apparently an annual Buttercup. It is not Anemone ranunculoides, as you suppose,——*F. H.*—1, Sweet-scented Tobacco (Nicotiana longiflora); 2. Scilia campanulata.

QUERIES.

2286.—**Acacia and Pampas Grass.**—I have sown some seeds of Acacia longiflora and Pampas Grass, which are just beginning to shoot up. How shall I treat them?—FLORES ET FLORES.

2287.—**Autumn and Winter Flower Beds.**—I would like to know the most suitable and effective hardy plants to collect now, for filling autumn and winter flower beds.—SARAH.

2288.—**Pruning Rhododendrons.**—Can any one inform me if I can prune Rhododendrons which are some 8 ft. high when the blossoms begin to fall? I have a recollection of having so done some years ago with success, but should be glad to know the orthodox time.—T. J. D.

2289.—**Propagating Deutzia Gracilis.**—When may cuttings be taken of this and what treatment do they require?—G.

2290.—**Antirrhinums in Pots.**—How should seedlings of this be treated to produce fine blooms? They are in 2-in. pots.—F.

2291.—**Vines.**—Will a small greenhouse, with a roof-space of 64 sq. ft., contain more than one Vine? If so, what is the best white Grape to plant with Black Hamburgh?—A.

2292.—**Sweet Briar.**—How is it that I cannot get Sweet Briar to succeed? It generally dies the second year after planting, seeming gradually to pine away. The soil is clay—about four-and-a-half miles from London. I have manured it, and given it liquid manure, but without effect.—SWEET BRIAR.

2293.—**Asphalte for Walks.**—Will some reader tell me how to asphalte a small walk?—W. K.

2294.—**Liquid Manure.**—Will "Public Analyst" kindly state what quantity per gall. of sulphate of iron, soda, or magnesia, is required to fix the ammonia in urine, &c.? and if either of the three are equally efficacious?—IGNORAMUS.

2295.—**Lily of the Valley not Flowering.**—Can any one tell me how to get a Lily of the Valley bed into flowering condition? The bed, which is an old one, was thinned in the early spring of 1879, and enough roots left to make three rows of plants. These bore not a single flower in that year; and this spring, although there were some buds, not a bloom has come to perfection.—W.

2296.—**Wild Flowers.**—I wish to make a collection of wild flowers. Can any one tell me how to dry them properly?—HAVELOCK.

2297.—**Vines Suddenly Failing.**—About two years ago a friend of mine had built an early Vinery between 70 ft. and 80 ft. long; he also made a good border inside, had everything taken out, and put in a concrete bottom and the usual compost, namely—good maiden loam, manure, &c., lime rubbish and bones, &c., all well mixed together. He grew a splendid lot of young canes for this house, and got them well established in 12-in. pots, and planted his border about the middle of March, 1877. They grew splendidly, made fine rods, and were in a fine healthy condition, and promised by their looks to be a first-rate and profitable house in the course of a few years. This year they made fine strong shoots and splendid bunches of Grapes, which I should think would have been from 2 lb. to 3 lb. each and lots of them. My friend gave a good watering two or three times, when they began to show symptoms of distress and gradually go back: the leaves curled up and blistered as if they had been stamped with large shot from the back of the leaf, the bunches shrivelled; and this once

beautiful house of Grapes looked in a most melancholy condition. I asked my friend what he had been watering them with. His reply was, "I have been watering out of those two petroleum barrels which I have put over the boiler and near the pipes to make the water tepid; I cannot think it is anything but that." I said, "Are they new ones?" He said, "No; they have been knocking about in the snow and frost for two years, and I thought they would be harmless." A row of beautiful pot Vines went just the same. I at once put it down to be those petroleum barrels, and making the water tepid had brought it out of the wood. We searched the border very minutely, but could not find any signs of Phylloxera. Still, it may be so; and I write this as it may give a good scope for a few old Grape growers to give their opinion on this subject, as it is most disappointing to see a lot of nice young Vines full of fine bunches of Grapes go off in this way.—G. C.

2298.—**Flowers for Button-holes.**—Will some reader give me the names of a few flowering plants that will grow in pots, boxes, &c., with the protection of a heated room, in which there is plenty of light. I want them for cut flowers (button-holes, &c.). I have zonal Pelargoniums, Heliotropes, Calceolarias, and Mignonette. The names of a few annuals, &c., would oblige. BUTTON-HOLE.

2299.—**Vines not Fruiting.**—I have two Vines in an unheated greenhouse. This year there is not a single bunch of bloom on either Vine. I shall be obliged to any reader for information as to the future treatment of the Vines, so as to ensure bloom for next season.—G. A. W.

2300.—**Insects on Plants.**—Can any one inform me of a good method of clearing plants of red spider and scale?—WEST HILL.

2301.—**Propagating Gloxinias.**—Will some one tell me the time and the best manner of propagating Gloxinias?—E. W.

2302.—**Moving Asparagus.**—Having made an Asparagus bed last March with three-year-old plants on the old system, I find I am compelled to move the bed, as I have made it over a cesspool. Will some one kindly inform me what is the best time to move the plants and which way of planting is the best? My garden is dry and has very nice mould.—R. H.

2303.—**Blight on Fruit Trees.**—Are not soap-suds a good remedy for this, and, if so, will not soda in solution be effectual?—R. H.

2304.—**Summer Pruning Fruit Trees.**—What is the proper time for summer pinching the following fruit trees, viz.—Apples and Pears (espaliers and pyramids), Plums (on walls and pyramids), and Apricots? Some say the middle of May, others the end of June.—W. H. K.

2305.—**Perennial Pinks.**—I want to make a bed of perennial single pinks. Will some one tell me the best kinds of seed to buy?—F. A. C.

2306.—**Ivy as a Border Plant.**—Will any one tell me how to grow Ivy as a border plant? The ground Ivy is too flat and not bright enough in colour, and we have not been able to produce a good result with the wall Ivy.—P. F. S.

2307.—**Skeleton Leaves.**—*S. E. S.*—What is the best method of preparing skeleton leaves? Can anything be bought for the purpose? Also, is there anything better than gum with which to arrange them in a book?

2308.—**Shelter for a Garden.**—I should feel obliged if some one could give me any advice as to lessening the full force of the wind in a narrow walled-in garden, standing on an exposed position. The walls are 9 ft. high, but the one facing south stands considerably lower than the north; consequently there is a sort of whirlwind inside the garden when the south-westerly gales blow. I have had fixed some iron standards on the top of the south wall, 7 ft. high, with wire netting strained between them; but this does very little good. The fruit trees against the top wall suffer very much, as the wind seems to strike against it and run right along. It has been suggested to me to pull down the east wall to allow the wind to escape, but I am unwilling to do this without trying other means. The objection to hedges is that they would take two or three years before they were large enough to be of any use.—T. P. HUGGINS.

BEES.

"BEE KEEPING FOR AMATEURS."

THIS is a pamphlet of some twenty pages, by Thomas Addey, and published at the *Bazaar* office, 170, Strand. It contains all that any one could expect to find in a pamphlet, and the matter is of a practical character. The following article on swarming will be seasonable just now, and give our readers some idea of the kind of matter contained in the book in question:—

"**Swarming.**—In a favourable season swarms may be looked for at the latter end of the month of May or the early part of June; when this is the case have a hive ready to put them in, and with a coarse cloth rub the inside before the bees are shaken into it. Have a cloth to set the hive on when the bees are in it; and, before turning the hive over, put a brick for the mouth of the hive to rest on, as this will cause the bees to commence building combs on that side nearest to the entrance, ensuring protection from invaders on the commencement of comb building. After the swarm for the most part has got settled in the hive, which will perhaps take half an hour, gently take the hive in the same position to the stand where it is to remain, and clear all away. As to the straggling bees, they will either find their new domicile, or go back to the parent hive, which will avoid the sacrifice of life which would have ensued had they been permitted, as in the old system of management, to remain through the day before removing the hive to its standing. After sunset give the new swarm a feeder, containing about 4lb. of sugar liquid, as this will greatly assist the bees in comb building, and the queen will soon find space to lay her eggs, and a strong healthy swarm will be obtained. On the other hand, if no assistance be given and dull weather confine the bees in the hive, an enfeebled stock and perhaps a total wreck will ensue—a calamity which may easily be avoided by a little trouble and a trifling expense."

POULTRY.

Insects in Poultry.—All kinds of birds are more or less liable to become infested with small insects, which irritate and annoy them to such an extent as often to seriously injure their health. Fowls when kept in confinement frequently suffer very much from a small insect which breeds very quickly amongst their feathers. We have met with cases in which the feathers round the neck and on the head have been completely covered with nits, and the body alive with insects; and it is hardly necessary to say with these thousands of pests feeding night and day on the bird that they soon become weak and emaciated. When fowls are troubled in this way, it is in all cases from an absence of the proper materials to enable them to free their bodies from the insects, for if the necessary means are at hand the birds are sure to take proper precautions for their own comfort and cleanliness. All they require is that there should be placed in a sheltered and dry place a quantity of cinder ashes, old mortar, or dry earth, for them to dust their feathers in directly they begin to find they have any insects on their bodies. This rubbish they will work so effectually through their feathers that the insects are very soon glad to take their departure. It may happen that from usage and long suffering and debility, the birds have not sufficient energy left to trouble about a dust bath even if it is provided for them. In such cases as these a little sulphur should be well dusted amongst the feathers, while the head and neck should be rubbed with an ointment made by mixing sulphur with lard. The great thing, however, is to have a heap of loose rubbish easy of access and dry, and then the birds will take care to keep their bodies free from all kinds of insects; but when no dust bath is provided, no matter how cleanly the house may be kept, the birds are sure to be troubled with vermin.

Nests for Sitting Hens.—During the warm season of summer the best place for hens' nests is on the earth, because that supplies just the amount of moisture that is needed to keep the shells moderately soft and the chickens healthy. Nothing is better for nest material than unwound straw-band, as it is soft and sweet. Straw is better than hay at any time. If made up elsewhere, we have found disused bloater boxes excellent things in which to place the nests, standing them in any quiet corner, and in dry weather giving the eggs an occasional sprinkle with warm water.—A.

An Egg within an Egg.—Mr. Towers, of Exeter, lately showed me an egg laid by one of his white Cochin hens, April 21 last. It weighed 4½ ounces, and measured 8¼ in. by 6¾ in. Mr. Towers being struck with this, to him, extraordinary large hen's egg, resolved to blow it and preserve the shell. He proceeded in the ordinary way to accomplish this object; but he found rather less than more come from this large egg. He shook it, and found something hard was left inside. He broke a little more of the shell, and to his astonishment there was another perfect egg loose inside, with shell apparently as hard as the outer one. The size of the inner egg is about ½ in. less than the outer one. Mr. Towers very kindly presented the curiosity to the museum, where it is looked upon with great interest; and I have no donbt the fact will be interesting to your readers.—Z.

Eggs not Hatching.—In reference to "Poultry Maid's" remarks about eggs not hatching on account of the chickens having died before arriving at maturity, the cause is probably a want of sufficient moisture under the nest. If hens are sat on the ground, it is seldom they fail to hatch if the eggs are fertile. We must imitate Nature in these matters. If a hen can arrange her own affairs, she sits herself in a hedge bottom, where the ground is quite damp. In the morning she starts off to feed, and returns with her breast and wings wet with dew. This tends to keep the eggs constantly moist; and without this being attended to one cannot expect strong and healthy chickens.—S. S.

Disease in Fowls.—Many of our fowls seem to be suffering from a kind of scurf, and lose all their feathers on the head. We are puzzled as to the reason, for they are regularly fed, have a good field run, and came to a quite new house last February. They are otherwise in good health, as they lay well. They also have a good supply of cinder ashes.—MAY.

Vermin in Poultry.—I have a hen sitting on thirteen eggs; what can I do to get rid of the vermin, as I find they are very numerous? Will they injure the chickens?—A SUBSCRIBER.

Keeping Brahma Fowls.—One of my Brahma fowls has something the matter with his legs; he has appeared weak on them for some time, but now they seem almost useless. When he is made to get up, for he continually lays down, he stands and trembles; he appears to have the cramp. Will any one inform me if there is any cure for it? I have a poultry run of 10 yds. by 3 yds. Can any one tell me how many fowls that space is capable of holding without injury to the fowls?—J. PETERS.

Fowl with Swelled Breast.—I have a fowl whose breast has swelled to such a size that it almost touches the ground when she walks. It causes her great pain and trouble in swallowing her food; sometimes I observe she even vomits after taking Corn, Rice, or any hard substance. Last spring she suffered from an enlarged breast, but after laying some of the finest eggs I ever had, sitting and rearing a brood, the swelling entirely disappeared, and has only lately made a re-appearance. Is there any remedy for this disease? as I should be very glad indeed to relieve her from suffering.—KATE.

HOME PETS.

Canary Losing its Feathers.—Has "J. R." kept it during the winter in a room where fire and gas are daily in use? If so, that will at once account for the bird losing its feathers. It is moulting, and I would suggest a judicious addition of strengthening and stimulating food, such as a small quantity of hard-boiled egg daily; also a pinch of maw and hemp seed occasionally; in the drinking water alternate saffron and a rusty nail; a lump of Bay salt between the wires to peck at is also a good thing. And next winter take care that it is kept in a room without fire or gas; for, although draughts are injurious, a mere cold temperature in any room is beneficial rather than otherwise. I have tried both plans, and found that keeping birds in a room with a fire they were moulting all the year round; whereas, last winter I kept mine in a room where the thermometer often stood at 32°, and I never had stronger or healthier birds.—FERNDALE.

Feeding Birds.—Young thrushes are very easily reared. Skylarks are much more tender, but they should both be fed in the same way—on hard boiled yolk of egg, sopped bread, and finely minced lean raw beef, to which you may add, if you please, a sprinkle of Poppy seed, all well mixed together into a moist paste. The birds should be fed hourly at least, oftener if possible, from daylight to dusk. The mess of crushed Hemp seed and bread with which unhappy nestlings are too commonly crammed is totally unfit for their food, and almost invariably kills them.—FANCIER.

Parrots Talking.—Will some one who has had experience in parrots kindly inform me at what age parrots may be taught to talk? I have a grey one which is only ten months old. Is this too young?—E. A. E.

Canaries in Newly-painted Cage.—Is it injurious to canaries to place them in a cage recently painted green and white?—E. V.

Taming Love Birds.—I have a pair of Australian love birds, and would like to know how to tame them?—L. M. A.

Food for Birds.—Will some one kindly inform me what is the proper food for redpolls, siskins, and yellow-hammers? They are all to be in one cage (which I am making).—CRYPTOGAM.

Worms in Dogs.—Can any one give me a simple remedy for curing worms in a very small Maltese terrier? I have tried a portion of Naldire's powders, but they do not seem to do any good. She refuses to take it in milk, and when I gave it in butter she was sick afterwards, and I tried it in the yolk of an egg. On the paper it says they must be given in milk or butter, so I fear the egg was no use. She has also a kind of skin disease—a sort of excrescence or wart comes, and when it dries it drops off. I was told to try turpentine, sulphur, and castor oil, and rub it into the skin, but it causes too much pain. Would washing her with carbolic soap do any good, or rubbing the warts with treacle as recommended for warts in cows? She is only four years old, and I should not like to lose her.—C. R.

AQUARIA.

Stocking an Aquarium.—It is startling to read "W. B's." directions for stocking an 18 in. aquarium, when he states that as many as twenty-two fish, besides tadpoles and frogs, may be put in. My own experience teaches me that such a number is three or four times too large; and if so many are put in, the number will gradually be reduced by death of the majority. In starting an aquarium, it should be remembered that it can only succeed as long as there is a proper balance between the animal and plant life—the former depending nearly entirely upon the oxygen the latter supply for their respiration. The amount of this will depend on the size, number, and condition of the plants, and also on the quantity of light and the season of the year. If too many creatures are put in, and more than the plants can sustain, the fish will soon be seen at the top of the water gasping for air, and making bubbles, a sure sign that the animal life is excessive. I consider it would be safer for a beginner to commence with three or four fish, and as the plants root well and flourish, a few more might be added. Surely fish require food regularly, like all other living things; for the water in the aquarium contains little besides air, and therefore unless something is given them, starvation must result. In feeding, care should be taken not to give more than can be eaten at once, or what remains will foul the water. Often at first, if the food is different to what they are accustomed to, but little is eaten. I generally give vermicella, broken up, which I throw in so that it sinks to the bottom of the aquarium immediately.—G. ABBOTT.

Gold Fish Dying.—I have two gold fish in a bell-glass which were perfectly healthy when I first had them (about a fortnight ago), but now they are covered with a kind of white scum; and several of the snails have died. Can any readers inform me what is the cause and remedy? H. E. H.

White Matter in Aquarium.—The cause of the film is having too much light on the aquarium. Place a piece of green calico on the back to keep off the rays of the sun and light; then take a small piece of sponge or a tooth brush tied to the end of a stick and rub it off the glass. To remove the slime from the fish take them out of the globe and place them in a pail; throw over them some silver sand, so that it may fall on the skin of the fish, which will cause them to rub themselves and entirely eradicate the slime without injuring themselves. —NEPA.

THE HOUSEHOLD.

To Cook any Green Vegetables or Cauliflowers, &c.—Put them into plenty of boiling water with a little salt, and when nearly cooked pour off the water and add fresh water, either cold or warm, and let it come gradually to a boil, when the vegetables will be delicious, and no strong flavour, as is generally the case with Brussels Sprouts, Cabbage, &c.—AN EXPERIENCED WIFE.

How to Pickle Eggs.—Can any one tell me the proper way to pickle eggs?—M. BRAIN.

Gooseberry Caterpillars.—As this is the time to get rid of the caterpillar from the Gooseberry trees, I can give your readers a certain remedy. First water the tree all over and then dust on thinly some powdered White Hellebore, which can be easily procured from the chemist. Last year my trees were first stripped of all their leaves and then the fruit quite withered, so that I had none hardly. I tried Tobacco-smoke; but that was a failure. I am sure the Hellebore is effectual, as I have proved it on many trees this year.—E. W. MORRIS.

The Amateur Gardener.*—This is one of Messrs. Warne & Co.'s useful shilling books, which has lately been revised and greatly improved in appearance. Its contents are such as any amateur gardener might peruse with advantage. Work to be done in each month is given, together with tables for sowing and planting, and, where necessary, illustrations are added. It is one of the cheapest as well as most practical books with which we are acquainted. Blank leaves are also inserted, which will serve as memorandum pages.

* "The Amateur Gardener," by Mrs. Loudon. New Edition. London: Warne & Co., Bedford Street, Strand.

Blight on Fruit Trees and Roses.—With the following mixture and a syringe I have effectually cured all my fruit trees from the black blight, as well as my Roses from grubs and green fly:—¼ lb. of black Tobacco, ½ lb. of Quassia (Bitter Wood); boil for four hours in 3 gals. of water, and then allow it to sand for twelve hours. After using about half the mixture, if it is found that more will be required, fill up again with boiling water, and it will be ready for use next day. It has no injurious effect on the blossoms.—MINIFIE.

Fly on Rose Tree.—As some of your readers may wish to know how to rid their Roses of that pest the green fly, I submit to them a

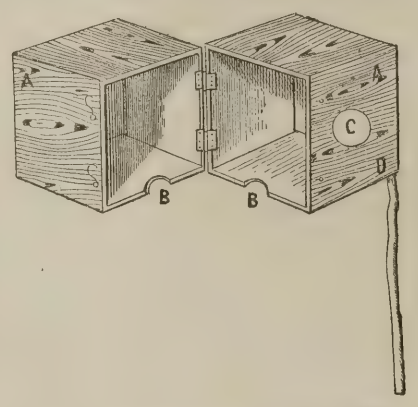


Fig. 1.—Fumigating box for Rose trees open.

plan that effectually cured mine last year. I constructed a box (A) to enclose the head of the Rose tree, divided and hinged, when closed fastening with two hooks and eyes; on the closing edges I glued strips of cloth to make it air-tight; in each end I inserted pieces of glass (C) opposite each other that I might see when I had sufficient smoke. In a corner of the box I placed a small flower pot (D), therein a few live embers and Tobacco paper, through the bottom

Fig. 2.—Fumigating box closed

of which and the box a piece of iron pipe, attaching a piece of rubber pipe to enable me me to blow through and obtain the amount of smoke I required. There must be a space (BB) cut in the bottom of each side of the box to allow the stem and stake to be enclosed, the cavities around which can be closed by a little hay, &c. I support my box on a stand similar to a photo camera; others may find a more convenient way. The box will be found useful for cleansing flowers in pots in a like manner.—A. H. HUNT, *Rickmansworth*.

Bone Dust as Manure.—I find this invaluable both for flowers and fruit, especially pot Vines and Strawberries; and it is not only a rich but a lasting manure, which I consider better than bones in a rough state. The latter are, however, best adapted for Vinery and fruit tree borders. For pot plants, such as Fuchsias, that bloom nearly continuously, if sufficient food be supplied to ensure fresh growth, a liberal sprinkling of this kind of manure will be found to be of the greatest service. In vegetable culture a sprinkling in the drills with Turnips and crops that are best pushed rapidly into full leaf beyond the attacks of fly and other insect pests, I have generally found bone dust most satisfactroy.—J. G.

Packing Strawberries.—Strawberries to be sent any distance should consist only of such kinds as will carry without risk of being damaged on the journey, as the finest fruit is of no value if it arrive at its destination bruised or otherwise damaged; even, however, in the case of the firmest-fleshed sorts considerable precaution is necessary in order to ensure success. I found from experience that the best material in which to pack Strawberries are the leaves of the green garden Orach (Atriplex hortensis); I therefore always sow a certain quantity of Orach seed in March or April so as to have young leaves available for packing purposes before the crop of Strawberries is fit for use, or soft spinach leaves would be a good substitute for the Orach. For packing I use shallow boxes of various sizes which do not hold more than two or three layers of fruit; I line the bottom with Orach leaves, and thereon put the Strawberries packed closely together. The first layer being finished, I again use Orach leaves, and so on until the box is full, when I add a good layer of leaves on the top; so that when the cover is put on, the boxes will, if necessary, endure hard usage for a couple of days without their contents being in the slightest degree injured. I have frequently sent Strawberries packed in this way both by post and rail over 200 miles, and once by steamer to Scotland, and they have invariably arrived in excellent condition. The sorts which I prefer for such purposes are La Constante, Sir Joseph Paxton, Waltham Seedling, Duke of Edinburgh, the Countess, Early Crimson Pine, Cockscomb, Fairy Queen, Lucas. Dr. Hogg, Unser Fritz, Ascot Pine-apple, and Duc de Magenta, all of which may be picked when quite ripe; whilst President, Frogmore, Late Pine, and James Veitch, should be gathered a day beforehand. It is of course useless to attempt sending such soft kinds as Black Prince, Marguerite, Keen's Seedling, jucunda, &c., however handsome they may be, any distance, as they would be sure to be more or less damaged. —F. G. H.

COVENT GARDEN MARKET.

WHOLESALE PRICES.

Cut Flowers.—*Per dozen bunches.*—Anemone, 2s to 6s; Azalea, 4s to 9s; Cineraria, 6s to 12s; Deutzia, 4s to 6s; Ferns (various), 3s to 9s; Heliotrope, 6s; Jonquils, 3s to 6s; Lily of the Valley, 4s to 12s; Lilac, 2s to 8s; Mignonette, 4s to 9s; Myrtle, 6s; Narcissus, 4s to 9s; Pelargoniums (zonal), 3s to 6s.; Pelargoniums (large flower), 6s to 12s; (double), 6s to 12s; (Rose-scented leaf), 6s; Spiræas, 6s to 12s; Tropæolums, 1s to 3s; Tulips, 4s to 9s: Violets (blue), 1s to 2s.—*Per dozen flowers.*—Abutilon, 4d to 6d; Arum Lilies, 3s; Camellias, 1s to 4s; Tree Carnations, 1s 6d to 3s; Eucharis, 4s to 6s; Gardenias, 2s to 8s; Roses (forced), 1s 6d to 6s.—*Per dozen sprays or trusses.*—Bouvardias, 1s 6d to 3s; Fuchsias, 2s to 4s; Primulas (double), 9d to 1s Stephanotis, 2s 6d to 4s.

Plants in Pots.—*Per doz.*—Arum Lilies, 9s to 12s; Adiantum cuneatum (ordinary), 6s to 18s; Begonias (flowering), 6s to 12s; Begonias (fine-foliaged), 6s to 12s; Bouvardias, 12s to 18s; Cytisus racemosus, 9s to 18s; Cineraria, 4s to 12s; Daphne indica, 4s to 6s; Deutzia gracilis, 9s to 18s; Dracæna (green-leaved kinds), 12s to 30s; Euonymus, 4s to 12s; Euonymus (variegated), 6s to 18s; Ferns (greenhouse and stove, various), 6s to 18s; Ficus elastica, 18s to 60s; Fuchsias, 6s to 12s; Gardenias, 24s to 36s; Lily of the Valley, 12s to 24s; Mignonette, 6s to 9s; Nasturtium, 3s to 6s; Palms (small), 18s to 60s; Pelargoniums (fancy), 9s to 24s; Pelargoniums (scarlet), 4s to 9s; Pelargoniums (double), 6s to 12s; Roses (hybrid perpetual), 12s to 24s; Spiræa japonica, 6s to 18s; Selaginellas, 3s to 4s; Virginian Creepers, 6s.—*Per pair.*—Maiden-hair Ferns (large), 4s to 7s; Palms (large), 15s to 42s; Amaryllis, 1s 6d to 3s each.

Fruit.—Apples (culinary), per bushel and barrel, 9s to 30s; Cobs and Filberts, per 100 lb, 120s; Grapes (English hothouse), per lb, 3s 6d to 7s; Grapes (imported Almeria), per barrel, 25s to 30s; Lemons, per box, 30s to 45s; Oranges (various kinds), per 100, 8s to 16s; Pomeloes, per dozen, 3s to 6s; Pine-apples (St. Michaels), each, 5s to 15s; Pine-apples (English hothouse), per lb, 1s 6d to 2s: Strawberries (early forced), per oz, 4d to 6d.

Vegetables.—*Per* 100.—Asparagus, 3s to 5s; French Beans, 9d to 1s. *Per dozen bunches.*—Carrots (outdoor), 4s to 5s; Watercress, 9d to 1s; Leeks, 1s 6d to 3s; Mint, 4s to 6s; Parsley, 6s; Turnips, 1s to 1s 9d; Radishes, 9d to 1s; Herbs, 2d to 6d. *Per doz. punnets.*—Cress, Mustard or small salad, 2s. *Per dozen.*—Cucumbers, 4s to 7s; Endive, 2s to 3s; Lettuce, 1s to 2s. *Per bundle.*—Horseradish, 3s to 6s. *Per lb.*—Shallots and Garlic, 6d; New Potatoes, 3d to 5d. Broccoli (Cornish) per crate, 10s to 18s; Broccoli (Sprouting), per bushel, 2s 6d; Savoys, per score, 5s; Chervil, per punnet, 3d; Corn Salad, per half-sieve, 2s; Mushrooms, per pottle, 1s 3d to 1s 9d; Potatoes (general store, round kinds), per ton, 100s to 200s; Kidney, per ton, 120s to 180s; Parsnips, per tally, 5s to 7s; Rhubarb (per dozen bundles), 2s to 3s; Spinach, per half-bushel, 2s 6d; Tarragon, per bunch, 6d.

GARDENING

REGISTERED FOR TRANSMISSION ABROAD.

VASE OF ROSES.

PERHAPS there is no operation in gardening which is performed with less taste, as a rule, than the arrangement of flowers in vases. We generally see a host of different kinds of flowers packed as close as they can be got together, great care being taken that the whole shall present an even surface when placed in the vase, and the object appearing to be to get as many different kinds of flowers into one receptacle as is possible. Now, to properly enjoy a vase of flowers, one kind, or at most two, should only be used. Take a handful of Roses or Gladioli or Dahlias, and place them in a vase, and they are effective; place them together and one destroys the effect of the other. The single Rose bloom, with a few leaves and buds, placed lightly in a small vase or glass, will afford ten times more pleasure than a handful of different kinds of flowers crammed into the same receptacle. The eye, as a rule, can only enjoy one object at a time, and this should be kept in view when arranging flowers in vases. We do not say, of course, that a few Fern fronds or light Grasses may not be used with advantage, provided they are tastefully disposed. An example of this may be seen in the accompanying engraving, the result of a sketch after the celebrated Regnier. It has been truly said that the highest art is that which renders most correctly the spirit of the subject without condescending to photographic detail, since we never can attain to both at once. When gazing on the charming group the subject of the accompanying engraving, we cannot but observe how fully this remark has been fulfilled; for, while recognising the graceful shape of the Cabbage or Provence Rose, still dear to many a Rosarian, it is obvious that the closely-packed petals are indicated rather than minutely copied; but as the likeness is not lost thereby, the gain in lightness and grace much more than compensates for the absence of detail. Our modern cultivators, in their endeavours to improve (from a gardening point of view) the queen of flowers, have almost succeeded in banishing the light and but semi-double Damask Roses forming the top of the group from our gardens; but to a painter's eye they will always furnish a spray of bloom such as he delights in. This is not, even in these days, forgotten by modern French artists, who tread worthily in the "spirit" rather than the footsteps of Regnier—the light and delicate sprays of Tea and Noisette Roses being very favourite subjects with them, while the massive blooms of a Pierre Notting and Maréchal Niel are sparingly used, and only as a counterfoil to some rich drapery, such as that before us.

ROSES EFFECTIVELY ARRANGED.

FLOWER GARDENING.

As I have had some experience and I think I may add decided success, in gardening, I cannot resist the temptation of writing to support "Justicia" in his reasons against the "bedding-out" system. My present garden is a mere strip—two borders 20 yards long and 1 yard wide, and a very small bit of ground which is used for Rhubarb, Beans, and Vegetable Marrows, and also does duty as reserve ground. Since February I have had a continual and increasing succession of flowers, which will not cease till Christmas, as I generally have Chrysanthemums on that day. If I had Christmas Roses I should have them in January, and therefore never be without flowers out-of-doors all the year round. Can any one who pursues the

"bedding-out" plan make such a statement? Our garden does not cost £5 a year—£1, or at the most £1 10s., being spent on plants, seeds, and bulbs; the rest going for soil, manure, and labour. Now, if I filled our borders with "bedding-out" plants spring and summer, and shrubs for winter, I should have to spend more than double this sum to have any effect, and I fear that many friends would miss the lovely bouquets of mixed flowers which it is my greatest pleasure to bestow. "Bedding-out" flowers are most unsuitable also for the flower mission, as they do not last well; moreover, the sick poor have double pleasure in seeing some old-fashioned favourite, the very perfume of which brings back pleasant memories of bygone days. Some of your readers may care to know the names of my various plants, and I will give them in something like the order in which they flower: From February to June—Primroses, Crocuses, Daisies, Forget-me-nots, Pansies*, Violas*, Polyanthus, Primula japonica (very showy and quite hardy), Wallflowers, Geum*, Columbine, Pinks, Oriental Poppy, Day Lily, Campanulas* of several sorts (white and blue), Delphiniums*, Clarkia, Nemophila, Scarlet Linum; from June to December—Bartonia, French Poppies, Blue Cornflower, Ox-eye-Daisy, Chrysanthemum Etoile d'Or, Geraniums, Calceolarias, Phloxes of various sorts, Carnations, Asters, Fuchsias, Zinnias, Verbenas, cream-coloured Marigolds*, Gladiolus, Anemone japonica alba, large perennial Coreopsis, Dahlias, Dianthus*, Nasturtiums, Chrysanthemums. Those plants marked thus (*) flower twice in the season from May till October, and I have generally a second supply of annuals to fill up the few blank spaces. Some good dwarf Roses give a desirable effect here and there against a most objectionable wooden paling at the back of the border. I have Lamarque, Maréchal Niel, and Cramoisie, yellow and white Jassimine, and a small Magnolia. Round the trunks of three hateful Lime trees I plant Sweet Peas and Major Convolvulus. So that I think your readers will allow that I make the most of my space, and enjoy a variety which would be impossible if I practised the "bedding-out" system. My friends wonder how I manage. I can only tell them that I love the flowers, and do not mind any amount of trouble for them. My two guiding rules are "Give and receive" and "If you want a thing done well do it yourself." I am always dividing my plants and giving them away, and I never refuse anything that is offered at any time of year. I do everything myself in my own particular border; digging, transplanting, pruning, and even watering are never trusted to a stranger's hand. A hired gardener is to my mind the *bête noire* of a mixed border—worse than cats or slugs even. I will conclude these remarks by adding that I seldom have to cut off dead blossoms. Gather your flowers judiciously when in their beauty, and you will have a much longer succession of bloom than if they were allowed to run to seed, and you will also give a great amount of pleasure to those who receive the lovely bouquets; and what bouquets can be made from a mixed border is only known to those who have had the pleasant experience which has fallen to me. AMATEUR M.

Improved Flower Gardening.—I was glad to see the discussion between Mr. Grieve and "Justicia" about the present system of bedding-out. The geometrical system now adopted in public gardens is to my mind hateful, but I think "Justicia" overdoes it in condemning all bedding plants as he does. I have, wherever I have lived, planted my garden with herbaceous plants: Daisies and Primroses in front; Hollyhocks at the back; Phloxes, Delphiniums, Pentstemons, Pyrethrums, Geums, Potentillas, Canterbury Bells, Foxgloves, Irises, Funkias, Lilies, spring bulbs of various kinds, in the middle; but, when the bulbs are dying down and looking untidy, and the Primroses going out of bloom, Verbenas, Geraniums, Calceolarias, Heliotropes, Phlox Drummondi, Zinnias, &c., are wanted to keep up the supply of bloom. Mr. Grieve condemns among others the Epilobium. I once took an old-fashioned house, in the garden of which there was a patch of E. lanceolatum (Willow-herb) about 6 yds. by 2 yds., and for two months in the summer it was a mass of bloom. It is the best plant for bees I know of; from sunrise until eight and nine o'clock at night my bees were busy upon it. —APIS.

FRUIT.

SUMMER CULTURE OF HARDY FRUITS.

Strawberries.—A good display of blossom on the Strawberry quarter, even after it has escaped the frosts, is not always a guarantee of a good crop if the summer culture of the plants be neglected. The weight of crop very much depends upon watering, mulching, and manuring, particularly in dry seasons, even though the ground may have been well enriched when prepared at the beginning. A mulching of half-rotten stable manure, or, in its absence, decayed hotbed manure or similar material, should be applied now, if not already done, covering the ground between the rows 2 in. or 3 in. deep, and well up to the collars of the plants. This will keep the ground uniformly moist, and at the same time render the placing of straw between the rows unnecessary, as the rain washes the mulching quite clean, and it serves the same end. Should manure not be available for mulching, short Grass may be used, and plenty of it; as, in the course of the summer, a thin layer of it soon shrivels up and vanishes. We prefer to delay mulching till the flower-scapes are up fairly, or even till the fruit is set in tolerably moist seasons when mauure is put on, as we find it stimulates the foliage too much, at the expense of the flowers; but in thin soil a mulching of some kind is indispensable, and in light or sandy soils it is the only way of ensuring well-swelled fruit. Before the mulching is applied to them the ground should be hoed and cleaned, and, if it be dry, also watered, and then mulched at once. When fresh plantations have to be formed in autumn, a year is just saved by layering the runners in good time, and keeping them stopped beyond the layer. Perhaps the very finest fruit for size and quality is obtained from plants that have been layered early in the season and planted in August; and when plantations have to be made, it is just as easy to give the plants some sort of preparation as not. With this object, a ridge of good soil should be laid between the rows and the runners laid on it; and when well rooted they should at once be transplanted—by August at the latest. There has been much dispute concerning the practice still in force in some parts of cutting the foliage off the plants after they have done bearing, in order to encourage a later growth. Theoretically, the practice seems wrong; but it is a fact that some of the best cultivators adopt it. Probably it succeeds better in some parts than in others. In late districts the practice is not to be recommended, as the second growth of leaves and crowns has not time to mature; but in early seasons, or in early localities, we think it is advisable to cut the oldest leaves off to let the light into the crowns. It is a noticeable fact that the first growth of leaves is always tall and rank, and that when they are cut away about July the second growth is short and stocky, the leaves broad, and the crowns prominent, like plants grown in pots for forcing; and in such cases the plants invariably bear well. Plants that have been forced in pots and afterwards planted out, make their growth during August and September, and have also the same squat habit, never making a rank growth; yet it is well known that they invariably bear enormously. It is proverbial that such plants never miss a crop. The cutting-over process may therefore be recommended when the crop is soon over, and the foliage old and rusty by mid-summer; but the operator should be careful not to cut too close to the crowns.

Small Fruits.—The practice of digging, either with the spade or the fork, among Gooseberry and Currant bushes during the summer is to be condemned. Nothing deeper than a push hoe should come upon the ground. All are benefited by thick mulchings, especially the Red Currant, which is more subject to honey-dew than the others in dry seasons; and the mulching, by keeping the roots moist and encouraging growth keeps it off. The Red Currant generally makes very profuse growth, and the trees are much benefited by summer pruning, which consists in removing the suckers which spring from the base of the plants, usually very abundantly, and in shortening the side-shoots of the main limbs something in the same way as bush Pear trees. Gooseberry bushes are also benefited by similar treatment; but Black Currant bushes, unless it is to thin out the shoots, may be left alone till the winter pruning. Raspberries only need a good mulching and abundance of water at the roots when the fruit is seeding; the weakest of the young canes should also be removed to give the others room, five or six being sufficient at a stool.

Fruit Trees.—The grand point in the culture of all fruit trees is to provide a successional growth of bearing shoots or spurs. Beginning with wall trees, and taking the Apricot first, the chief points of summer culture consist in disbudding in good time, so as never to allow the shoots to get crowded and smother each other, and afterwards in keeping the front or fore-right roots regularly pinched at every two or three joints, and layering in leading shoots wherever they may be needed to cover the wall. The Apricot produces its fruit on the shoots of the previous year's growth, and also on spurs along the branches, and both should be assiduously cared for and encouraged as above directed. The roots prefer a rather firm and well-drained soil, but require, nevertheless, an abundant supply of water during the fruiting season. Much of the rain which falls upon sloping borders of a hard texture runs off, and they are often drier than is imagined. They should therefore be either slightly forked over or mulched, to prevent evaporation, and when the summer is dry well watered. We have seen trees on the open wall absolutely flagging for want of water under such circumstances, which is very injurious to the trees. Dryness at the root means the starvation of the present crop and the failure of the next.

Peaches.—With these the main thing is to keep the shoots as thinly and regularly distributed as possible. They should first be allowed to make a good growth, and then be laid in loosely, keeping the fruit always well exposed to the sun from the commencement. The root treatment is the same as for the Apricot, only as the Peach is more subject to insects, red spider particularly, mulching and watering is of even more consequence in its case, and is far more effectual than the syringe or insecticides in keeping down these pests. Mildew, however, must be destroyed by sulphur dusted on the leaves or applied by the syringe; or some of the antidotes for that disease may be tried; the "Mildew Composition" has a good name.

Plums and Cherries.—These should be treated, as regards pinching and training, like the Apricot, keeping them spurred-in in front, and letting the terminal shoots which are laid in extend as much as they will, except such as are getting the lead too much, which should be stopped. Watering and mulching are highly beneficial, as both the Cherry and Plum root near the surface of the ground.

Bush and Pyramidal Trees.—Apples and Pears on dwarf stocks require little more attention than the thinning out of the shoots and pinching the lateral ones on the main limbs, so as to admit the light freely among the branches and keep the trees in shape; but rigid formality is to be avoided. The natural bush shape is as good as any, and quite as ornamental, while it affords the greatest facilities for ex-

tending the bearing capacity of the trees. The terminal shoots of the main limbs should not be stopped at all except when very strong, or when necessary to retain the balance among the branches. Shoots that are allowed to grow always furnish the most fruit-buds. The directions also apply to trees on the natural stock, when these are trained and pruned; but the orchard is the place for them, and there thinning the branches out occasionaly is all that is needful. J. S.

Orchard House Fruit Trees.—During this season of the year there is plenty of work in orchard houses; the trees should be syringed morning and evening plentifully, and freely watered—a healthy free-growing plant will take up a considerable quantity. The trees should also be surface-dressed. I have found malt-dust mixed with sewage excellent for that purpose, but it must be prepared a month before it is used, and after the water has been added to the dust the heap should be spread out about 1 ft. in depth; do not buy the malt germs, but the dust; malt-makers will know what is wanted. Thinning the fruit must now be commenced, leaving that at the base of a shoot; thin out isolated fruits and those on leafless shoots; but as in unheated houses the stones are not yet formed, the present thinning must not be final; pinch ill-regulated shoots, and put sticks to pyramidal trees that are not straight. As the Peach has a tendency to grow into a standard, all the top shoots of pyramids must be pinched; as a general rule, leave about five leaves; ventilate abundantly. Apricots may now be placed out-of-doors for a succession; in southern districts they will ripen well in the open air. Plums and Pears may also be set outside to leave room for the Peaches and Nectarines. Look closely after the brown aphis; Quassia-chips 4 oz. to the gallon of water, and 4 oz. of soft soap added when applied, will keep the trees free from this pest; wash the under surface of the leaves thoroughly.—R.

THE SHRUBBERY.

The Best Hydrangea for Shrubbery Borders.—Hydrangea paniculata is destined to become as plentiful in our shrubberies as the Lilac. It is quite as hardy, far more showy, and lasts much longer than the Lilac, but it lacks the sweet scent of that well-known plant. It is quite the best of the now numerous family of Hydrangeas. I have, planted on an ornamental border, various Hydrangeas, consisting of varieties of H. japonica, hortensis, and Otaksa; but the H. paniculata quite eclipses them all. One plant of it, which three years ago was put out of a 4-inch pot, is now quite 4 ft. in height, and as much in diameter. Last summer it bore twenty-eight fine spikes of bloom, varying from 6 in. to 18 in. in length, according to the strength of the wood, the largest spikes being on the top shoots. The soil in which it grows is a moist stiff loam. The plant seems to want abundance of moisture at the root in hot weather, to enable it to produce its gigantic trusses of bloom. H. Otaksa ranks next as regards showiness, and it is dwarfer in habit than the old hortensis. Its foliage is much the same in shape as that of hortensis or japonica, but a little more pointed, and more glossy and smooth.—W. D.

An Easily-made Fumigator.—I have made a fumigator which I think perhaps others might like to know of. I have a brass syringe, with shifting screw jets, &c., to it. I have made a perforated metal cylinder, with a bottom also perforated; this just fits into the barrel of the syringe, and is turned over at the top so as not to move up or down when the jet is screwed on. I then fill it with Tobacco, and stick a fusee end in this, set light to it, put it in the barrel, and screw either the single jet or rose on. The working up and down of the piston rod slowly ignites the Tobacco; and so I get and keep up a stream of smoke about 18 in. long; if the smoke is wanted more spread, I put on the coarse rose. Once filling the Tobacco holder is enough to do a number of plants in my conservatory. I do it of an evening, and keep the house closely shut up till the morning, and then syringe the plants with water.—C. J. W.

House and Window Gardening.

BASKETS FOR ROOM PLANTS.

Among the many receptacles that have been named for concealing the pots of room plants, I do not observe baskets. After trying many plans, we have found nothing so good as baskets of close texture, painted, and varnished a warm brown (I believe called japanning), a colour which detracts from nothing and harmonises with everything, the brown earth and green vegetation being a safe example to follow. We send pots of the various sizes used to the Blind Asylum, and there the baskets are made to fit them; they have stout wooden bottoms, as the weight of the plant is too great for basket-work. When not required they fit one within another, and take up very little room. The varnish prevents the adherence of dust and dirt. Fresh Moss is laid on to cover the surface of the pots. Our large baskets for groups of plants 7½ ft. to 10 ft. in circumference are made of open basket-work, and are lined with Moss. And here let me remark that some of the species of Hypnum are the best in the long run for this purpose; though there are many Mosses more beautiful, but they do not last so long. The Hypnums grow on dykes or loose stone walls, and also on the exposed roots and trunks of trees, and come off in fine large flakes, very suitable for linings. It seems to be generally forgotten (as also with Seaweeds) that Mosses are complete plants, with roots and seeds, and that it is in vain to expect such species as are plucked up from among Grass, or scratched off the soil, to last long. By having two lots of Hypnum it can be changed weekly, and if spread on the floor and well watered, it is wonderful how revived and refreshed it becomes for the next week's use. In summer, when all Mosses are, so to speak, out of season, we find a good substitute for our linings in turf; first mowing it close and then cutting it into strips long enough to go round the inside of the basket. The Grass grows in a couple of days, and looks very well, peeping through the basket-work. If we were within reach of a hill, or "links," where fine turf was to be got, with such plants as Polygala, Potentilla, Thyme, Cistus, Galium, Euphrasia, Linum, all flowering amongst it a charming addition to the plant basket would be the result; as it is, we must be content with our road-side turf, drawing out Dandelions and Plantains, and being satisfied with a daisy or two. I fancy these plain brown baskets do not attract the eye from the plants—the first point to be considered, in my opinion, in any arrangement, either in the garden or house, or with cut flowers. To enhance the beauty of one plant by contrasting or combining its form or colour with others, is a safe and legitimate attempt; and we see such pleasing effects every day in the fortunate grouping or position of trees in the landscape (too seldom by any design of the planter), down to the Mosses and Lichens grouped on the trunks of these trees. But when man's inventions in the way of stone and lime, statuary, rockery, gold and silver vases, Majolica ware dishes, elaborate wire baskets, and glasses of fantastic forms, are attempted, then the difficulty is so great, that nine out of ten fail; and the tenth will be a very questionable success in the eyes of the true lover of plants and honest student of Nature. F. J. H.

Window Plants.—Windows should now be gay both inside and out. Such plants as are inside should be as near the glass as possible, regularly and well watered, but they should not be permitted to stand in pans or saucers of water for any length of time; their young growths should be pinched if they become too long. Myrtles, India-rubber plants, Callas, and similar plants that have smooth and thick leaves should be gently sponged; but Pelargoniums, Heliotropes, most kinds of Ferns, and such plants as have hairy leaves should be taken out-of-doors and syringed occasionally, in order to clear them from dust. Window boxes, if well drained, allow superfluous water to pass off freely; water may, therefore, be administered plentifully without any fear of its stagnating about the roots. A good loamy soil, mixed with leaf-mould or decayed manure, makes a good compost for plants in boxes. The beauty of Calceolarias is soon over, as is also that of several other flowers; therefore, some preparatory means must be adopted for supplying their places with fresh material, and for this purpose Pelargoniums, small plants of Acacia lophantha, Fuchsias, Nasturtiums, Lobelias, Mignonette, &c., should be held in readiness. Plants now in the boxes should be induced to display themselves to the best advantage, and for this purpose if a very narrow strip of wire netting be run along the top of the box and made to lean backwards, and another piece bent downwards in front, and some of the shoots of the plants attached thereto, a large and showy surface is obtained. Brackets and suspended baskets should likewise be well furnished with suitable plants, such as the hardier sorts of Adiantums, Polypodiums, Aspleniums, Aspidiums, Athyriums, Pterises, &c. Ivy-leaved Pelargoniums, Lobelias, Petunias, and the small-leaved dwarf-growing Ivies, are also very pretty when used as basket plants.

Fine-foliaged Begonia (B. Rex variety) suitable for walls and rocks.

GLASSHOUSES & FRAMES.

Begonias for Walls and Rocks.—The back walls of shaded plant houses, which are generally unsuited for light-loving flowering plants, cannot be better utilised than by covering them with Ferns, Selaginellas, fine-foliaged Begonias (similar to that here represented), and graceful trailing plants of elegant habit. There are several ways in which these wall gardens may be formed, but the best which I have yet seen adopted is to cover the face of the wall with a coat of peat and living Sphagnum Moss, 2 in. or 3 in. thick, these materials being held in position by means of zinc hexagon netting fastened firmly to the masonry. Under such circumstances scandent Ferns, Begonias of different sorts, Pothos argyræa, Tradescantia, Panicum variegatum, and trailing Aroids may be planted for immediate effect, and spores of quick-growing Ferns may be shaken over the moist surface as a preparation for future display. Frequent syringing is requisite, especially in dry, hot weather, until the plants have become established. In warm, shady plant houses or conservatories these walls of verdure are not only beautiful additions to the other arrangements, but they also serve a useful purpose in preserving the atmosphere in that humid and genial condition which is so essential to the welfare of most plants.—B.

Ferns for Bouquets.—Onychium lucidum is one of the best Ferns for cutting, as it not only has very elegantly-divided fronds, that render it suitable for bouquet work, but it is very lasting in water when used in a perfectly mature state. To have this and others in the latter condition, they should be grown well up to the light, where they can have plenty of air to thicken and harden them, as much of their enduring powers depend on this; thin, flimsy fronds withering almost as soon as they are removed from the plants. Davallias are mostly lasting, but the best of them all for bouquets is D. bullata—unfortunately, a deciduous variety, and therefore only available for use during the summer.—S.

Herbaceous Calceolarias.—It is surprising to see how little these beautiful greenhouse plants are grown; and few know what a loss they have in not including them amongst ther list of spring seeds. Somehow people suppose that Calceolarias are very difficult and troublesome flowers to deal with; but in reality they are not any more so than the Cinerarias and Primulas, &c., which no one thinks of doing without. The chief secret in growing Calceolarias to perfection is to constantly shift them into larger pots, as once they begin to grow, they quickly fill the smaller ones with roots. If the seed be sown any time between March and the end of May, in pots of loam and silver sand, barely covering the seed with a little sand, and then placed in a warm greenhouse, they soon germinate and will be ready for potting off into 3-in. pots in a few weeks, after which they may be shifted on into larger sizes as they require it, till they occupy the ones they are to flower in. They must be kept carefully guarded from frost through the winter in a cool pit or frame, and brought into the greenhouse and placed near the glass when beginning to throw up the flower stems. Plenty of air should be given, to cause a stout growth. It is a great improvement to both flowers and foliage to water the plants regularly twice or three times a week with liquid manure. About the beginning of May, you will be rewarded by a grand show of these beautiful flowers, varying in hue from the deepest shade of brown and crimson to the palest yellow; many are very richly marked and blotched, while others are self-coloured. They will be found very useful, either for the greenhouse or for exhibition purposes.—W. A. G.

SWEET-SCENTED FLOWERS FOR A COOL CONSERVATORY.

THE following are all plants which emit an agreeable fragrance, either from flowers or foliage, and in some instances both are powerfully scented; as for instance, Diosmas, Myrtles, and Geraniums. If a good border of turfy soil could be made many of the plants would do better planted out than in pots. This would include all climbers, and such plants as Luculia 'gratissima; Roses such as Maréchal Niel and Lamarque Heliotropes when planted out under glass attain a large size, and are nearly always in flower if in a light position. Mignonette planted in a similar position with the seeds picked off is virtually a shrub. Magnolia fuscata should be planted against a wall or pillar as should also the Jasmines. Hardy shrubs, such as Lilacs, double Thorns, Syringas, Belgian and Japanese Azaleas, should be potted in autumn and planted out again when the blooming is over. If they could be forced gently, an early bloom will be obtained that would be appreciated. Bulbs of course, such as Hyacinths and Narcissus, will be had early in the season, with Lily of the Valley, Tuberoses, and Lilies of various kinds following on in succession; but one might write a treatise on this subject and yet not exhaust it. I am assuming that the frost will be kept out, as although a house altogether unheated might be made interesting with hardy plants, or those requiring a slight protection only, yet the enjoyment is much enhanced if the structure be heated so as to keep out frost. Adenandra fragrans, Aloysia citriodora, Azaleas (Japanese and Ghent), Boronia megastigma, Carnations (Tree and Clove), Citrus (all the Orange family are suitable), Cytisus Everestianus, Cheiranthus odoratissimus (Night-scented Stock), Diosma ericoides and others, Doryphora Sassafras, Daphnes (all the family), Eupatorium odoratum, and Eucalyptus globulus, will all be found suitable. The foliage of the Eucalyptus yields an agreeable perfume, and when the plants become too large they can easily be pulled up and young ones planted, as it is one of the easiest of plants to raise from seed. French Lavender, Geraniums (all the old scented-leaved kinds, such as Lady Plymouth, Prince of Orange, Radula major and minor, citriodora, &c.,) Humea elegans, Heliotropes, Hyacinths, including the Musk Hyacinth), Jasminum grandiflorum and others*, Lonicera fragrans*, Violets (in pots specially prepared and potted early), Lilium auratum, giganteum, and others, Lily of the Valley, Pinks (including the old white and Anne Boleyn), Lilacs, Thorns (including Paul's new double scarlet), Magnolia fuscata, Luculia gratissima, Mandevallia suaveolens*, Myrtles, Pergularia odoratissima*, Pittosporum Tobira*, Prostanthera violacea, Rhynchospermum jasminoides*, Mignonette, Rhododendrons (Himalayan species and hybrids, notably Edgworthi), Roses (especially Teas), Harrison's Musk, and Petunias (single and double). Those marked thus * are climbers. H.

Ceropegia elegans.—This is a pretty climbing plant, bearing sage-green maroon-spotted flowers. It thrives well planted out in any ordinary heated greenhouse, and continues in bloom for a long time. It is not a common plant, but we believe it is to be found in Messrs. Carters' nursery at Forest Hill. It is a native of India, and a very interesting plant.

Ceropegia elegans; a greenhouse climber; flowers sage green spotted with maroon.

Fuchsia Rose of Castile.—This, though an old kind, is still a favourite with many growers. It is extremely floriferous, lasts a long time in bloom, and is equally well adapted for the formation of large specimens as for growing in small pots for general decorative purposes. Amateurs with small glass accommodation, as a rule, content themselves with treating the Fuchsia as a summer-blooming plant, not being aware that it is possible to prolong the flowering season far into the winter months. By growing such kinds as lend themselves best to this particular method of culture, and by affording them the treatment necessary to impart luxuriance and vigour of constitution, not only may the Fuchsia be had in bloom in a cool greenhouse during the late months of the year; but the same plants will flower again freely in early spring. Rose of Castile is the very best variety with which I am acquainted for this purpose; for, unlike the generality of the kinds commonly grown, it really does not appear to need any period of complete rest, retaining its foliage throughout the winter, and bursting into bloom again on the advent of the fine sunny days. It is altogether a most valuable variety and one which should be in every amateur's greenhouse. Plants from cuttings struck in spring and grown along freely during the summer months are preferable to older specimens. The cuttings should be taken off with four leaves, inserted in sandy soil, placed in a cool, shady frame or hand-light until well rooted, when they should be carefully potted-off into small pots, in a nice free compost of two parts leaf-mould and one part fibrous loam. Keep them in a frame, watering carefully, ventilating freely, shading from hot sun, and syringing morning and evening in hot weather. Shift on as required until the plants come into 6-in. pots, using more loam for the final shift and potting more firmly. Place a neat stake to each plant as soon as the need for such support is seen, pinch out the flower buds as they appear, but do not attempt to control the growth in any way by stopping the shoots; for this Fuchsia, when left to itself, naturally assumes a pleasing pyramidal form. By the latter end of August place the plants in the open air in a light but sheltered situation, allowing the flowers to develop after the middle of September, and placing the plants under cover by the latter end of the month. The result of this treatment will be a good show of bloom almost up to Christmas. After the flowers are all faded water only just enough to keep the foliage fresh. By the middle of February fresh growth will be forming, and the plants should be then assisted with a little manure water. By the beginning of May there will again be a good display of bloom.—J. CORNHILL.

Old Chinese Primula Plants.—It is a common practice with many, as soon as their Primula plants have done blooming, either to throw them away or set them in some out-of-the-way corner, where they are so much neglected that they are of no further use. Young seedlings are raised to take their place under the impression that they will make better plants the following winter than the old ones, if cultivated until that time. In many cases this is a mistake, as old plants, if given the same attention as seedlings, make much finer specimens, and produce much more bloom—until they are at least two years old—than the best yearlings. In order to suit certain special decorative purposes, we annually grow a number of seedling Primulas in 3-in. pots. About this time these are shifted into 6-in. pots, and they make fine, free-blooming, most useful plants during the succeeding winter. They bloom much earlier than the seedlings. When the plants become more than two years old they are rather inclined to get leggy; but any not having this objection may be grown for three years or more. Where large numbers of plants are raised from seeds, it often happens that they do not all produce first-class blooms. When they have all bloomed once, the worst should be thrown away, and only the best kept for growing on. Plants which have been growing in 6-in. pots may be taken out of them, the ball of soil about the roots reduced, and then be re-potted into the same sized pot. Our old Primulas were re-potted some time ago. Since then they have been kept in a cold frame with the lights over them, and shaded on very bright days; and they are now making many young leaves. Besides this, they are emitting little crowns all round about the old main one, and it is these which will produce so much bloom next autumn and winter, and make the plants appear a great mass of bloom, when seedlings will only be producing a few flower spikes from their single crown. In potting, a little of the best loam obtainable may be used, and this should be freely mixed with a good quantity of decayed manure, silver or river sand, and charcoal or wood ashes. The pots must be well drained and the soil should be put in very firm about the roots. After this, if the plant should fall on one side, two or three little pins of wood from 4 in. to 6 in. long should be placed down through the leaves into the soil close to the stem, so as to steady the head until the stem has become stronger. Any frame with a glass light to it, or other house, will do to start them into growth. As soon as the roots begin to penetrate the new soil, cease shading them altogether, and grow them as much exposed to the sun as possible during the summer, as this is the best way

ensure all soft-wooded plants blooming profusely and well during the dull days of winter. —CAMBRIAN.

ROSES.

Indoor Climbing Roses. — Vigorous-growing varieties of Roses, especially such as Maréchal Niel, Gloire de Dijon, or Lamarque, that do not flower freely if pruned to any great extent before growth commences in the spring, will now, after the principal flowering is over, require attention; whilst the plants are young, and before they have filled the space which their heads are destined to occupy, they need not be much reduced; but when they have filled anything near all the room available, if cutting back is not carried out some time in the year they get crowded with useless, weak wood, little able to produce handsome, full-sized flowers. To avoid this, now that the spring blooming is over, a portion of the large, strong, old branches may be cut out near the point on the main stem from which they spring, leaving a stump, the latent eyes of which may be expected immediately to break into growth. These will form strong vigorous branches, which will produce the best flowers next season. This removal of a portion of the old wood annually, to be replaced by new, may be carried to the extent of one-third or one-fourth the entire plant, which, so treated, will always contain a sufficient quantity of young, vigorous flowering growth, and will not attain a dimension beyond that which there is space for, and that profusion of weak, useless shoots that results from insufficient pruning will not exist. The plants at the same time should be thoroughly well washed, so as to free them from insects. If there is any mildew upon them, a liberal application of water impregnated with sulphur will be found useful. Where planted in inside borders, or in a position where the root space is confined, manure water, given so as to soak the whole mass of soil as far as the roots can extend, will be of the greatest possible use. This may with advantage be repeated from time to time for the next two months whenever the soil requires moisture.

Fly on Roses.—Continual efforts should be made to keep down aphides. Regular use of clean water without stint, applied with the syringe and garden engine, will effect the object; their numbers may be reduced in the ordinary way by crushing with the fingers or the small sugar-tongs-shaped brushes made for the purpose; but in thus crushing them on the buds the matter from their crushed bodies tends to injure the character of the flowers, unless they receive a good washing immediately after the insects are destroyed.

Potting Autumn-struck Roses.—Rose shoots taken off early in autumn, and at that time made into large cuttings 6 in. or 8 in. in length, and inserted deeply in cold frames, will by now, if all has gone well, have formed a considerable amount of roots. Those that are required for pot purposes should be taken up very carefully, so as not to break their newly-formed fragile fibres, and at once potted; 5-in. pots will be large enough, draining them well, and using the soil a little lighter and more sandy than such as is advisable when the plants have got better established, at the same time making it firm. As the plants will have pushed their shoots a considerable length, they should for a few weeks yet be kept in frames, gradually giving more air as the roots lay hold of the soil, and when they are fairly established transfer them to the open air, plunging them in ashes or Cocoa-nut fibre.

Green Fly on Roses.—The following is a simple, quick, and effectual method of clearing Roses of this pest:—Pour water slowly from a watering pot with a fine or medium rose over the leaves infested, holding them very slightly with the left hand, gently moving the fingers all the time; the insects will wash off easily the moment they feel the touch, and cleaner than if the plants were syringed for a length of time; they cannot bear the slightest contact with the fingers and water without going. If you shake the shoots occasionally during the water falling upon them, it will also help to clear them of the drowned flies. No wash is needed by the above method.—W. A. T.

The Hardy Dragon Tree (Dracæna indivisa).—Nearly all the Dracænas or Dragon Trees at present in cultivation are generally treated as tender tropical plants requiring considerable artificial heat in order to grow them successfully. Recent experience has, however, convinced many plant growers that they will luxuriate in a much cooler temperature than has been supposed, and during the past two or three years we have seen them grown freely in the London parks, planted out in ordinary soil, and treated as sub-tropical plants. The species we now illustrate is very hardy in constitution, and is not only valuable for cool conservatory and sub-tropical decoration, but is also perfectly hardy when planted out in Devonshire, Cornwall, and other southern counties, and it has also withstood the winter on warm dry soil in many parts of Ireland. A good strong plant of this Dracæna is always an effective object when planted out in sheltered positions on lawns during the hottest months of the year; and plants of it so treated are fitted to withstand a much lower wintertemperature than when they are grown in a heated structure. It is readily propagated by means of cuttings of the stem, and for pot culture we recommend a compost of fresh fibrous or turfy loam, peat, and sand, the two former in nearly equal proportions, and the plants should be well rooted and established before they are planted out. In Hampshire this plant has been known to endure 16° of frost, and if the dead leaves are allowed to remain around the stem—that is, allowing Nature to protect herself—it will stand even more cold than that. It may be mentioned that the practice of pulling off the decayed leaves of this and similar plants is often the cause of their death.

The Hardy Dragon Tree (Dracæna indivisa).

VEGETABLES.

Earthing Celery.—This operation should be performed only on dry days, taking care that none but well-pulverised dry soil is permitted to come into immediate contact with the plants. The soil should be chopped down on each side of the trench, and turned over to dry early in the morning, well breaking the lumps as the work proceeds. When the plants are dry—which they will be towards the middle of the day—the operation may be commenced by carefully removing any decayed leaves from their bases; then gather the leaves neatly up together with the left hand, and firmly place the soil round the plants with the right. When all the plants have been served thus, the sides of the trench should be evenly chopped down and the surface left neat and tidy. Many people tie up the plants with matting previous to earthing, and some use Celery collars; but neither of these plans is necessary: they only involve needless trouble and labour, and earthing can be performed by any intelligent man without resorting to such troublesome means. It is certainly not necessary to earth up Celery when it is growing rapidly, and moreover it is bad practice. A little earth, pushed down after a heavy watering to prevent evaporation, is all we should give during the growing season, and we know it to be a fact that some of those who grow the finest Celery in the country do not earth until full growth is attained; indeed, some of them do not earth at all, but effect the blanching by other means. The repeated earthings which Celery receives in the majority of gardens are not only harmful to the crop, but the cause of a great waste of time and labour. Common errors are frequently made in Celery culture—one being that in earthing-up the plants too much soil is applied at one time, by which the hearts are covered in, and are thus made to bulge out on one side and become deformed; whereas, when the operation is more lightly done, as well as oftener, the heads are kept upright and the growth is much more vigorous. Another error, which is perhaps the worst, is "earthing" or banking up the crops too heavily in autumn, or before winter sets in. This is a very common practice, especially among amateurs, who often cover their Celery over head and ears. This is sometimes done with a view to keep out the wet and frost from the crops, but in such cases the plants fail to grow from want of air; in fact, as already indicated, the plants are buried, and consequently soon become rotten; and though the wet weather may be blamed for this, it may even happen when the ridges are covered with litter or boards. It is therefore obvious that earthing should be done more sparingly, taking care that the growing hearts of the plants are well above the ridges, especially in the case of late crops. If this be done, there will seldom be any reason to complain of crops rotting, however damp and severe the winter may be. Those who protect

the ridges to fence off the weather appear to overlook the fact that the means employed for this purpose prevent the escape of moisture by evaporation from the earth, in consequence of which the plants are more apt to rot than if their tops had been freely exposed to the air.

Thinning Onions.—By thinning the crop out well you will have large Onions, and in fine seasons probably well ripened; but when a plentiful crop of good sound keeping Onions is the object, it is a mistake to thin them too much. As a rule, small or moderate-sized Onions are the best ripened; and a small Onion is just as good, in a culinary point of view, as a large one, if not better. For instance, small well-ripened Onions are preferred for pickling purposes; and to secure these it is the usual practice to sow the silver-skinned variety thickly, and leave them unthinned, and in this way "button Onions," as they are called, are produced. By thinning the plants out we should only get thick necks wholly unsuitable for the purpose. Long-keeping qualities are very much sought after by the Onion grower; and it is well known that well-ripened samples only will keep, and these are more certainly secured by leaving them thick in the bed. To leave the plants 7 in. or 8 in. apart, as is often recommended, is a mistake, unless Onions for exhibition only are required; but where sound bulbs—say about as broad as the mouth of an ordinary teacup—will satisfy, leave the plants close enough together to touch each other when they attain that size—that is, supposing them to be sown in rows 7 in. or 8 in. apart, as Onions always should be sown, in order to facilitate the clearing and stirring of the ground. If sown broadcast, then the plant should have a little more room. When thinning the crop, leave them about the length of the forefinger apart, and by autumn the ground will have the appearance of being fairly thatched with Onions, of a size and quality fit for any culinary purpose. Cottagers, who generally have not too much room in their gardens, often crop thicker than is here recommended; and beds may sometimes be seen that would astonish thin croppers. Sometimes the rows are only 5 in. apart, and the plants from 2 in. to 3 in., and the bulbs fairly clustered over one another, literally covering the ground—very nice samples, and thoroughly ripened; and they will keep good till June the following year. In order to satisfy oneself on this matter, let any one leave a thick and a thin row together, and weigh the produce at harvest time.

Earthing-up Potatoes.—As this is the season for earthing-up Potatoes, a description of the mode of culture that I have for several years practised with success may be useful. The ground in winter is well prepared by being dug up in ridges and exposed to frost. About Lady Day I have it forked down, spread manure on the surface, and then plough in the Potatoes 6 in. or 7 in. deep and 2 ft. to 2½ ft. apart. When they begin to break the ground I harrow them over with a pair of very light harrows on a sunny day, which kills all the small weeds. When about 8 in. or 9 in. high they are hand-hoed, and then require no further attention till they are dug up the first or second week in August. Last year I began to dig them on the 29th July, as the Regents had begun to grow out. In digging, they all hang to their haulms, and considerable caution must be exercised in handling them, in order that they may not be bruised. They should then be put in a long narrow heap, and covered with dry litter or Fern, thatched with "reed" or prepared straw to keep them dry. This straw is similar to that used in this neighbourhood for the roofs of cottages and other buildings. The straw for making reed is threshed and combed by hand. In a fortnight or three weeks they should be looked at, to ascertain if any are diseased; and, if this is not the case, they should be gradually earthed up, the ridge being left unearthed to prevent them heating. Last year I had some under a north wall which were not picked over until Christmas, when they were removed to the lime and sand floor of a dark cool cellar, where they keep much better after the end of the year than in ridges or caves out-of-doors. The disadvantage of earthing-up is that the first leaves are buried, and a fortnight of the short season before the disease sets in is lost, which must be taken into consideration. I believe the crop is no heavier for earthing, and the practice entails much extra labour at a very busy time. My remarks apply to good, well-drained ground; in wet soils earthing may be advisable. I find that the true Lapstone Kidney is one of the best kinds, and it does not run out if grown in the same ground; I have grown it here for seventeen years. York Regent is one of the best late Round kinds. With me it is a heavier cropper than Paterson's Victoria, and more free from disease—both are excellent in quality, but the latter is better for cropping between, as the haulm is erect in its habit. The York Regent soon runs out, or degenerates, if grown year after year on the same ground; but on planting fresh seed it produces, with good cultivation, very heavy crops. Although the tubers readily skin, and appear very unripe when taken up, the quality is excellent afterwards throughout the whole season. Many of the cottagers in this neighbourhood have followed my advice in reference to Potato growing, and have, I believe, found the advantage of doing so.—J. G., *Exeter*.

COMING WEEK'S WORK.

Extracts from a Garden Diary.

June 14.—Sowing Parsley in cold pits for winter use; potting off seedling Campanulas; planting out Walcheren, Snow's Winter White, and White Cape Broccoli; clearing of Cabbage stumps, manuring the ground, and getting it dug up ready for another crop; shifting Caladiums, Balsams, Amarantus, and Coleus into larger pots; potting young Primulas, and placing them in a cold frame where they can be kept close until established; sowing Champion of England and Nonpareil Peas, and French Beans; also London Coleworts, and Incomparable Cabbage; planting Asparagus and some April-sown Lettuces; also planting Celery in trenches for main crop, and another batch of Cauliflowers and Couve Troncuda; putting in Lavender cuttings out-of-doors under a hand-light; thinning Onions, Carrots, and other root crops.

June 15.—Sowing Giant White Cos, the Favourite, and All the Year Round Lettuce; potting on Cinerarias and Primulas; putting out Celery plants; raking down and levelling all flower borders and beds; layering Vicomtesse Héricart de Thury and President Strawberries on pieces of turf 4 in. square; potting Stocks, Asters, Alyssums, Lobelias, and Calceolarias for room and conservatory decoration; sowing Syon House Cucumber, Chicory, and American Cress; planting Scotch Kale, Fearnought Cabbage, Savoys, Broccoli, and Vegetable Marrows; watering thoroughly outdoor Strawberries that are swelling their fruit, and afterwards covering the ground with short Grass, in order to keep the fruit clean; nailing in shoots of wall trees, and removing all curly leaves infested with insects; pegging down Tropæolums and Verbenas, and staking up Pyrethrum flowers.

June 16.—Potting Musk plants for autumn use; also Lady Plymouth Pelargoniums; sowing Shilling's Queen and Atkins' Matchless Cabbage, and various kinds of Endive, Lettuce, and Radishes, also Golden Ball and American Redtop Turnip; thinning Apples, Pears, and Plums; putting in cuttings of show Pelargoniums and Mimulus in frames, and layering British Queen Strawberry runners for next year's forcing; sowing Canadian Wonder and Long-podded Negro French Beans; striking Peas and getting them earthed up; thinning Turnips, and Spinach.

June 17.—Sowing Coleworts and Little Pixie Savoys; planting out another row of Cardoons; dividing and planting out double Daisies; thinning out Pears where hanging too thickly; clipping Box edgings; mulching Peas with rotten manure; tying in all the leading shoots in Peach houses and watering the borders where required; clearing off Lettuce stumps and Spinach; shifting Chrysanthemums into their flowering-pots; also Achimenes; sowing Negro Long-pod French Beans and a little Parsley; planting Endive, Lettuce, Melons, and Gourds; also Celery and April-sown Cabbage, and making up vacancies among Winter Greens; tying up Carnation flowers; thinning Turnips and stopping Vines; hoeing between all growing crops.

June 18.—Sowing Silene pendula and Forget-me-Nots; potting on large Coleuses and Cockscombs; putting sticks to Fuchsias and Phloxes and tying them out; turning gravel walks to give them a fresh appearance; nailing in all the leading shoots of Plums, Apricots, and Peaches, and giving the latter a good washing with the garden engine every evening to keep down red spider and other insects; cutting back Ivy where overgrowing windows; gathering green Currants for bottling; potting seedling Cyclamens, and placing them in heat; also potting some Violets and Lobelias for indoor decoration; sowing Mignonette in pots; also Melons and Cucumbers; planting land just cleared of early Peas with Snow's White and Cooling's Matchless Broccoli, also Neapolitan Cabbage Lettuces on Celery ridges; putting Poinsettias in heat to induce them to produce a supply of cuttings; examining Peach trees carefully for green fly, and sulphuring hot-water pipes in Vineries to ward off red spider; syringing Ferns to wash off thrips, and putting paraffin on Apple trees to kill American bug.

June 19.—Planting out Spiræas; also Autumn Giant Cauliflower; taking up Hyacinths; netting Cherries that are ripening, also Strawberries; digging out trenches in which to plant Cauliflowers, and manuring others intended for Celery; plunging out-of-doors large plants of Dielytra spectabilis that have been used for forcing; sowing Snowball, Red Globe, and American Strap-leaved Turnips; planting Autumn Cauliflower and Purple Sprouting and Early White Broccoli.

Glasshouses.

Passifloras and other creepers must now be thinned, taking care to preserve as large a quantity of young wood as possible without overcrowding, and permitting the shoots, after they reach a certain height, to hang down in graceful festoons. Keep up a good succession of flowering plants from greenhouses and frames to replace those going out of flower.

Pits and Frames being now clear of bedding plants, may be filled with annuals, Pelargoniums, Fuchsias, Hydrangeas, Begonias, &c., in order to forward them for the decoration of the conservatory. Hydrangeas are now coming into bloom, and require some assistance in the way of manure water; any shoots not furnished with flower-buds should be removed and used for purposes of propagation. By means of plenty of ventilation—complete exposure, in fact, during fine weather—retard the show Pelargoniums. Old roots of Cyclamens not bearing seed-pods may be transferred to a frame having a north and shady aspect. The young ones must be kept in a good growing state. Plants of Spiræa japonica that have done flowering should be transplanted into a plot of ground that is rich, moist, and warm.

Primulas and Cinerarias.—Both Primulas and Cinerarias, if sown as advised, will shortly be fit for placing in 2½-in. pots in soil consisting of three-fourths good loam and one-fourth rotten manure and leaf soil in equal quantities, with a good sprinkling of sand. When potted, put them into frames facing northwards, as these plants cannot bear exposure to full sunshine, to break the rays of which, when very bright, shade with a piece of netting or thin canvas. Cinerarias should stand on a bed of ashes that will hold moisture and maintain a humid atmosphere about the plants; they cannot endure being placed on shelves exposed to dry currents of air. Place Primulas on inverted pots, so as to keep them up near the glass, or they will become drawn and long in the leaf-stalks. After potting, keep the lights closely shut down at night with only a little air on during the day until they have commenced to grow freely, after which give air plentifully night and day.

Pinks.—Cuttings of Pinks for forcing should now be put in and potted on singly as soon as rooted. They are easily managed, do not occupy much room, and, with a little warmth, afford a succession of sweet-scented flowers alike suitable for bouquets or vase decoration. They are not much subject to insects, though green fly sometimes attacks the young leaves; its presence, however, is easily detected by the leaves beginning to curl up. Dipping and syringing with Tobacco water will be found the best remedies. The plants must always be sufficiently supplied with water, or they get into a stunted condition.

Salvia gesneræfolia.—Cuttings of this put in some time ago will be ready for moving into 6-in. pots. This most useful winter-flowering subject naturally assumes a bushy habit, but to furnish the plants with plenty of shoots near the base, the points of the leading growths should now be pinched out. These ought to be at once plunged out-of-doors in a sunny sheltered situation. It is a free grower, and makes roots rapidly. In the course of six weeks' time the plants will require moving into larger pots for blooming, keeping them outside till the beginning of September.

The White-flowered Abutilon Boule de Neige blooms nearly during the whole year, producing in succession its beautiful drooping flowers, alike suitable for display on the plant or for cutting. It is of the easiest possible management. Cuttings of the half-ripened shoots, 5 in. or 6 in. in length, inserted singly into 3-in. pots in sand, kept moist, shaded, and covered with a propagating-glass in a little warmth, will strike in a few weeks, and make nice small specimens that will bloom through the autumn and winter. A. vexillarium and A. vexillarium igneum are equally worthy of cultivation, flowering freely in small pots with ordinary greenhouse treatment. The two latter, grown with single stems 12 in. or 18 in. in height, and then stopped so as to form a bushy head, make beautiful miniature standards suitable for table or window decoration, or for placing in the greenhouse, where, if raised on inverted pots, they greatly relieve the even surface of dwarf-growing subjects.

Acacias and Cytisus.—Acacia Drummondi and A. armata are the two best varieties

for pot culture. They are of easy growth, and not liable to die off suddenly through either a superabundance or scarcity of water, like many hard-wooded plants. Young plants of these Acacias that have been grown on from a small state, and others that are larger and have been cut back and re-potted after blooming, will in most cases, have made sufficicient growth, and should be exposed in the open air; this is necessary to fully harden and mature the growth and to induce the formation of flowers, for if the plants be kept under a glass in a growing state all the summer they will not produce flowers in such profusion as if thus exposed. By getting them out-of-doors in good time they will be in a condition to bloom earlier through the winter. The very useful winter-blooming Cytisus racemosus superbus, which is much better than the common C. racemosus, requires to be similarly treated. If a few examples of this free, delicate, yellow-flowering plant be grown, a succession of its highly fragrant flowers may be had through the winter.

Fruit.

Thin the shoots and berries of Grapes as required; only allow one bunch to each lateral, and pinch the shoot at the second eye beyond the bunch. If the borders are indoors, see that they are thoroughly moistened. In the Peach-house border watering must also be attended to, and liquid manure supplied now and then. Disbudding, syringing, and other daily operations will require attention. Top-dress Cucumber beds immediately the young roots are seen protruding above the surface, thin out superfluous laterals and decaying leaves, and always maintain a regular supply of young and good bearing wood. Never permit too many fruits to be on one plant at a time, as they only prevent each other's development. Syringe both Melons and Cucumbers twice a day with clean tepid water; but if mildew be suspected, mix with it a little flour of sulphur. Strong and healthy plants militate against red spider; therefore manure water must be freely applied to Cucumbers. Melons ripening require to be kept a little on the side of dryness. As the frames are now cleared from bedding plants, the latest-sown Melons should be put in them; these will come in late in the season. The beds need not now be made so substantial as was necessary earlier in the season; if a good supply of last autumn's leaves are at hand, they may be made of at least one-half of this and well-prepared manure. Three feet in depth will be enough now; beds of this description will be sooner cool enough to receive the plants than those recommended earlier in the season. In localities not favourable to the growth of Tomatoes, or where a difficulty has been experienced through attacks of the disease with which this vegetable has of recent years suffered, it would be advisable to grow some in frames. If the plants are put into 12-in. pots and plunged in the ground, and the frames elevated on bricks, so as to give increased head-room, good crops may be secured. The principal thing to be observed in their culture is to keep the plants sufficiently thinned and well tied out, not allowing them to suffer for want of water, and giving enough air to induce stout growth.

Vegetables.

Whenever a crop is done with, manure and dig the land on which it grew, in order to have it in readiness for something else. Nothing impoverishes the ground so much or looks more untidy than runaway vegetables. Peas in windy places are sometimes apt to partially escape from the sticks which support them; when this tendency is first noticed, if a strand of rope yarn is run along the rows on the lee side and linked here and there to the sticks, it will turn them back in the right direction and prevent them from being broken down.

Make a further small sowing of Early Horn Carrots; there is a frequent demand for small, young Carrots, which it is always best to anticipate. Sow Spinach once a fortnight in cool, damp-bottomed land that has been deeply worked; in dry weather it is sometimes a disappointing crop. Sow Turnips to succeed those just up; burnt earth or ashes from any substance except coal has an invigorating influence upon the growth of Turnips in dry weather. The Red American Stone and Orange Jelly are the best Turnips for sowing at this season. Avoid, if possible, the necessity for sowing in freshly-dug land. If the land has been prepared a week or so, the moisture, even in dry weather, will have risen by what is termed capillary attraction, and by drawing the drills rather deeper than necessary or desirable early in the spring, the seeds may be laid in moist soil, and germination thereby assisted.

Continue planting, as opportunity offers and space becomes vacant, such crops as Brussels Sprouts and early Broccoli. A sufficient breadth of spring-sown Cabbages should also be planted, giving them room according to their kinds; small varieties, such as Cocoa-nut or Little Pixie, will do if they be placed 15 in. apart each way, whereas those of the Enfield Market class should stand 18 in. asunder in the rows with 2 ft. between. Savoys should have a similar space allotted to them, according to the small or large variety grown. A few spring-sown Red Cabbages should also be planted 18 in. from plant to plant, and the rows 20 in. apart. With the large number who cannot find room until something that has preceded them is cleared off, there is no chance but keeping the plants until the required space is at liberty in the beds in which they were recommended to be pricked out a short time ago, from which they can be removed with very much less check than if allowed to remain in the seed-bed until permanently planted. The main crop of Celery may now be planted, choosing the first favourable opportunity when the weather is showery: for, although the plants may not be so large as to take any harm in the nursery bed, they will receive less check from moving than if planted later when they are larger.

CONSTRUCTING A FERNERY.

THE great point in constructing a Fernery is to provide a sufficient body of soil of the proper description for the roots to work in, at the same time making due provision for maintaining the same in a sweet healthy condition. Ferns vary somewhat in their requirements with respect to soil, according to their respective natures, some thriving only when planted in pure peat, others growing stronger when a certain portion of loam is added thereto, many kinds being benefited by the addition of good leaf-mould. Every kind of Fern, however, with which I am acquainted will grow more or less satisfactorily in good fibrous peat; therefore I would advise that this form the sole ingredient employed in an indoor Fernery. The beginner cannot, therefore, make a mistake, but will have the satisfaction of knowing that each plant is provided with a suitable rooting medium. In a small house the best arrangement would consist of a walk in the middle, not extending quite to the end of the structure, but allowing space for the formation of rockwork. On each side of the walk a sloping bank of soil must be thrown up, placing here and there amongst it pieces of sandstone, brick burrs, or any material of a similar nature, arranging them as naturally and informally as possible, and creating here and there cosy little nooks, which may prove congenial homes for some of the more delicate rooted species. Some kinds, especially mountain varieties, only give satisfaction when the fibres can touch as it were some inorganic substance. These kinds love moisture at the root, but it must be accompanied by most perfect drainage. I would, however, warn those attempting the formation of a Fernery not to overdo the matter in this respect. Just enough rocky matter to ensure drainage, and to impart a natural appearance is necessary, and no more. The system, too, often followed of building up a rockery in a solid way, leaving here and there a shallow pocket, cannot be too severely ensured. Even the small growing kinds languish in such places, and as for those of a naturally vigorous habit they can never, when thus starved, afford any true idea of their beauty and manner of growth. Virgin cork may be used just in the same manner as the hard materials named. It may be buried in the earth here and there, allowing it to project from the soil. Any naked portion of the wall may also be covered with it. There are also some kinds of Ferns, such as the Elk's-horn and the Davallias, which, if wired on to cork with a little Sphagnum Moss will thrive very well thus treated, provided that the Moss is kept moist during the summer months. The lower portion of the rockwork may be bordered with such Mosses as Selaginellus Kraussiana and helvetica, and other species may be introduced with good effect in other parts of it. Care must be taken to plant the strong-growing kinds at the back, coming gradually down to such as are distinguished by their small proportions. With respect to a fountain, if such be desired, it may be placed according to the taste of the owner. Our own impression is, however, that unless arrangements can be made for ensuring a constant supply of pure water this part of the affair is best left out, especially in a house of limited dimensions. J. CORNHILL.

Do Ferns require Sunshine?—Ferns dislike bright sunshine, thriving best where the atmosphere is constantly moist and the light of a subdued description. At the same time, it must be admitted that this interesting family of plants is often subjected to treatment which is far from being in accordance with their nature and requirements. Many growers make a practice of either heavily shading their Ferns during a great portion of the day, or of creating dense perpetual shade by damping the glass with a mixture of some kind, not appearing to realise the fact that Ferns, like other plants, require a certain amount of light to build up their tissues; and that when unduly deprived of its influence, the foliage cannot well attain its due amount of healthy vigour. There are some species which will thrive in very light-excluded situations; others, again, such as the generality of the Adiantums, require a considerable amount of light, and are even benefited when they catch at some part of the day a portion of the sun's rays. Many of our most beautiful stove species, such as the Gold and Silver Gymnogrammas, seldom retain their vigour and beauty long unless placed in a very light position. Those who would wish to form a correct idea of the requirements of the Fern tribe in this respect should visit their native haunts. There they will see at a glance that every plant receives a large share of filtered light; they will note that in every case, although the plant is well sheltered from the glare of a hot sun, it invariably turns towards the light; and in most cases it will be found that either the morning or evening sun reaches it. If the grower takes Nature for his guide in this matter he cannot err. Whether his plants be grown in a glass structure or in the open air the same rules will apply. A slight shade of tiffany, to be applied only when needed, is all that is required; and if the structure has a north aspect, but little artificial shade will be required. The plants will get a maximum of light without being subjected to the aridity which is apt to prevail in a structure so situated as to be exposed to the summer's sun. These remarks apply equally well to the construction of Ferneries in the open air. Choose, if possible, a situation where the plants are completely screened from the noonday sun, but where they are at no time densely shaded. The north side of a wall or building, or a situation in the immediate neighbourhood of tall trees, where the early morning sun, as well as its departing rays, penetrate—where the atmosphere is at all times cool and moist—is just the place in which Ferns thrive, and attain a luxuriant development.—J. C. B.

Hardy Climbers for Basket Handles.—Scarcely any hardy climber is so well suited to this purpose as Ivy, for it is evergreen, permanent, and will bear any amount of trimming. Showy handles would detract from the gay colours of the flowers massed in the baskets. A margin of Ivy and the handle covered with the same material, whether green or variegated, greatly improve the appearance of iron wire baskets. Some baskets should be dressed with green, some with golden, and some with silver-leaved Ivies; and the floral fittings should be such as would harmonise with these colours. Petunias, Verbenas, Phlox Drummondi, and similar plants, are exactly suited for baskets.—A. D.

Hardiness of Lobelias and Primulas.—It may be interesting to your readers to know that the beautiful Lobelia cardinalis, which bears scarlet flowers and dark brown leaves, has lived out in a border through the whole of last winter, a sprinkling of ashes merely being used to protect the roots from frost. Also Japanese Primulas are quite hardy here, and have lived through the two last winters in the open ground.

This is in Herefordshire, by no means a warm climate.—M. C. H.

The Sickle-leaved Catchfly (Silene falcata).—This pretty Catchfly forms perennial tufts consisting of numerous curved, awl-shaped, hairy leaves. The flowers are borne singly on stems about 6 in. high, and are about ¾ in. across; the petals are divided into halves down to the throat, as are also the central appendages, the colour of the whole being a creamy white. It is a native of the Bithynian Mount Olympus.—W.

HARDY JUNE FLOWERS.

THE engravings on our next page represent some hardy plants which flower in June, in addition to those we gave last year. Although some here given are not the best hardy flowers that bloom in June, they are all well worth growing.

Silvery Yarrow (Achillea Clavennæ).—A dwarf, white-leaved, distinct plant, 6 in. to 10 in. high. Flowers white, in neat heads standing well above the foliage. A good and easily grown rock plant, and also an excellent subject for the front rank of the mixed border, where the soil is not too cold and stiff. On congenial soils it might be used as an edging plant for the sake of variety. Increased by division of the tufts in autumn or spring.

Lebanon Candytuft (Æthionema coridifolium).—A little novelty in leaf and flower distinct from any other kind in cultivation. Flowers rather large, of a pleasing flesh-colour prettily veined with rose, in small dense clusters. It does not possess the rude vigour of our evergreen Iberises, among which it is placed by some authors, but it is none the less valuable for being unlike them, and is fitted for association with a dwarfer and more select class of subjects. it should be planted on warm and sunny parts of the rock garden, in well-drained sandy loam. Increased by cuttings or seed.

The Pot Marigold (Calendula officinalis).—This excellent old plant can be had "gay" late in autumn, as well as in the early part of summer. Our beds of it are dazzling, and the flowers double to the centre; such a blaze of colour could not, at this season, have been had with any other plant. After saving sufficient seed, we cut down the plants to the ground, thoroughly soak the beds when needful, and in about three weeks the "evergreen tufts of leaves" are again in full growth, and by the end of August the second crop of flowers begins to appear. A top-dressing of fine soil helps the shed seed, which produces plants in abundance, and a constant succession of flowers.

Mountain Coronilla (C. montana).—An erect, free-flowering, slightly glaucous perennial, 15 in. to 18 in. high. Flowers yellow, fifteen to twenty in each umbel. Suitable for the mixed border, rougher parts of the rock garden, margins of shrubberies, and naturalisation in ordinary garden soil. Division or seed.

Amoor Pink (Dianthus dentosus).—A dwarf but sturdy and large-flowered species, 5 in. or 6in. high. Flowers more than an inch across, of a fine violet-lilac, with a regular dark spot formed of purple streaks at the base of each petal, producing a dark eye in the centre of the flower; the petals toothed at the margin, and bearded at the base. The rock borders of sandy well-drained loam. Seed.

Broad-petalled Geranium (G. platypetalum).—One of the handsomest plants of its family; 1½ ft. to 2½ ft. high. Flowers more than an inch across, deep violet, with streaks of a darker, almost reddish hue. Borders, or naturalisation, in ordinary soil. Division.

Scarlet Lychnis (L. chalcedonica).—A well-known old border plant, 1½ to 3½ ft. high. Flowers scarlet, in clusters. There are in cultivation single white, double white, and double scarlet; the best is the double scarlet. Borders, in light rich loam. Division and seed.

Gaillardia picta.—This is a handsome border plant, producing large showy flowers, rather profusely and in long continuance. It requires rather a dry warm situation and rich light loam, as the plants are apt to perish in heavy soils in cold wet places. Where they are apt to die in winter they may yet be used in mixed borders, treated as half-hardy annuals; for if sown in a mild hotbed at the end of February or the beginning of March, they may be grown into good plants, and a full display of their fine flower-heads obtained as early as upon those which may have withstood the winter in the borders. They are propagated by cuttings in autumn or spring in the manner of general bedding plants, and by division in spring, assisted afterwards by slight heat if the locality is a cold one.

Coppery Monkey-flower (Mimulus cupræus).—A dwarf, very free-blooming kind; 8 in. to 1 ft. high. Flowers coloured, both on the inside and out with yellowish-copper, or reddish-brown—almost bordering on crimson, with reflexed, velvety, and somewhat transparent margins; lower lip prominent and plaited near the throat, which is dotted with purplish-crimson. Leaves usually tinged with red. Borders, or the margins of beds of American plants, in light moist loam and peat. Division or seed, from which it varies much.

Dark-eyed Viscaria (V. oculata).—This is a showy and beautiful hardy annual, well suited to the hardy flower border. The seed should be sown in autumn or spring, and the seedlings thinned out when large enough. It grows about 6 in. or 8 in. high, and bears a profusion of rose-coloured blossoms having a dark centre.

Fraxinella (Dictamnus fraxinella). — A showy border-plant, covered with glandular

Fraxinella (Dictamnus fraxinella).

hairs, exuding a strongly scented and inflammable oily resin; 1 ft. to 2 ft. high. Flowers pale purple, in long terminal racemes; there is also a white variety. Borders, in any soil, but usually best in a dry one. Where it grows vigorously, it would be worth placing in isolated tufts in the Grass near the margins of shrubberies, in unmown spots. Division or seed, which should be sown when gathered.

Gladiolus Colvilli.—This is one of the hardiest of the Gladiolus, and one that is best suited for permanent situations in borders or in front of shrubberies. If planted in deeply-trenched well-manured soil any time from December to April, and left undisturbed, it will at this season of the year yield abundance of spikes of purplish-lilac blossoms. The bulbs of this variety are very cheap, being obtainable at about 10s. per hundred.

Horned Violet (Viola cornuta).—A very ornamental and popular species, 6 in. to 10 in. high. Flowers nearly all the summer, pure white. Beds, edgings, borders, &c.; best in sandy loam, though it will grow almost anywhere. Division, cuttings, or seed.

Double-flowered Silene pendula.—This is really worth growing, as its semi-double and double flowers are larger, of a richer colour, and continues in beauty much longer than those of the single kind. Indeed, this plant has in addition the merit of furnishing useful flowers for cutting, as many of the blooms are as double as those of a Pink. Lovers of spring gardening will find this double variety worthy of attention.—D.

Mulching in the Flower Garden.—During hot dry weather vegetation frequently suffers more from heat and drought on strong land—from its tendency to crack into deep fissures, and thus part rapidly with its moisture—than on light sandy soil, where the surface remains intact. There is, too, a vast difference in the power of various soils, often even in the same locality, to absorb heat during bright sunshine, and it is on those soils which, either from their colour or composition, may be termed hot soils, that the value of a thin covering of some non-absorbent retentive substance will be most appreciated. For several years past I have mulched nearly all the beds in our flower garden, and with the most satisfactory results. In the case of all plants which are benefited by a little extra nourishment, we mulch with short manure; but in the case of others that usually make growth enough without any such support we simply cover the beds thinly with short Grass, from which the plants derive much benefit, and the saving of labour in watering is very considerable. Indeed, I did not think that any amount of watering would produce the same result, because it tends to encourage surface rooting, and every now and then something occurs that, for a short period at least, prevents the accustomed supply being given, and in a hot soil like ours the young surface roots soon perish; where, however, the beds are mulched there is no occasion to feel uneasy about the water supply. In most cases it is best to put on the mulching as soon after planting is finished as is convenient. Verbenas, Violets, Ageratums, Calceolarias, Heliotropes, Iresines, Coleus, Tricolor Geraniums, &c., we mulch with manure decayed sufficiently to break up easily with a fork. I have generally used horse manure, but last season I obtained it from a bullock-yard, the manure from which is of a cooler character than that from stables, and better suited for a hot soil. The expense of the manure compared with the well-being of the plants and the saving of labour in watering is a mere trifle. It should be placed evenly all over the surface of the beds with the hand, and where the appearance of the manure is objectionable, about 1 in. of fine soil should be placed over it, and all plants that require pegging down should receive that attention in good time. Pelargoniums of the scarlet section will stand a good deal of drought in a deep soil; but in hot summers a thin covering of short Grass or Moss is a great help to them, and, if put on in time, will prevent their losing their lower leaves. This class of plants usually makes growth enough, and therefore all they require is some thin covering to check evaporation. Petunias, when once established, even on the hottest and driest soils never seem to require either watering or mulching; a dry hot season, in fact, suits them best, and very showy inexpensive beds they make when trained low on sticks bent over the beds. Cocoa-nut fibre refuse is excellent material for mulching flower beds. It looks well and keeps the ground very moist, and it is, moreover, so cheap that no one need be without it.—H. S.

Brompton Stocks. — These are very beautiful in borders at this time of the year, but are more abundant in small gardens than in the parterres of the rich. The giant scarlet, however, so massive and withal so fragrant, is worthy of a place in any garden, large or small. Not less beautiful, too, but much rarer, is the Giant White, a grand Stock that, when well grown, will produce marvellous spikes of bloom. I have seen them on plants 3 ft. in height, 12 in. in length, and equally fine all round.—D.

Achillea aurea.—This is one of the showiest, if not the showiest, dwarf member of its large family, and is admirably suited for the rock-garden, for choice borders, for bedding-out, or for edgings. It grows 12 in. or more high, has finely-cut leaves and bright golden-yellow flowers, abundantly produced, and appearing for a long time in succession on young plants recently transplanted into rich ground.—J. C. N.

Silvery Yarrow (Achillea Clavennæ).

Colvill's Gladioli (G. Colvilli).

Scarlet Lychnis (L. chalce lonica).

Pot Marigold (Calendula officinalis).

Dark-eyed Viscaria (V. oculata).

HARDY JUNE FLOWERS.

ANSWERS TO QUERIES.

2246.—**Rhododendrons not Flowering.**—Rhododendrons do not require pruning; they naturally assume a dense, compact habit, and the employment of the knife in their case could only be productive of evil consequences. Plants which make a free growth seldom fail to flower unless the situation be of a very sun-secluded nature. The Rhododendron, like other flowering shrubs, requires a certain amount of light and air to mature the wood. Perhaps the trees in question are in a shady situation. This season, however, bloom is more or less scarce in most places; the past summer being deficient in solar heat, the blooms did not form.—J. C.

2247.—**Araucaria Losing its Branches.**—A top-dressing of good sound loam would in all probability prove beneficial. Be careful, however, not to let it touch the stem of the tree. It is not at all uncommon for the Araucaria to lose its lower branches when too closely environed by other trees and shrubs. When standing in a free, open spot, it seldom suffers in this manner. If your tree is shut in by shrubs of an ordinary description, we would advise their prompt removal, or the tree will probably suffer to a serious extent. —J. C. B.

2265.—**Tacsonia Van Volxemi.**—Young plants of this climber require but little pruning. Encourage them to make liberal growth by means of copious waterings and frequently syringing the foliage in hot weather. In the case of established specimens, the strong shoots may be shortened back, and all weakly wood thinned out. When this plant is trained to the roof, it is better to allow the individual shoots some freedom of development. If permitted to droop down somewhat irregularly from the roof, it presents a more natural and far more pleasing appearance than when a more rigid course of training is pursued. —C. B.

2259.—**Narcissi Failing.**—We can only surmise that the bulbs are deficient in vigour. As soon as the foliage decays, take them up and plant them in a rather cool and sheltered situation. The Narcissi, as a rule, delight in a liberal supply of moisture at the roots, and thrive best in a loamy soil. Take out the natural soil about 18 in. in depth, fill up with a good compost, consisting of turfy loam and a little leaf-mould and well decomposed manure. Plant so that the bulbs come about 2 in. under the surface, and do not disturb them again. Thus treated, they should flower freely every spring. C. B.

2271.—**Oleanders not Blooming.**—We should suppose that the plant in question does not get enough light and air when expanding its blooms. As soon as the flower buds appear, admit air freely. It would, indeed, be better to place the plant in the open air in a very sunny position during the summer months. The growth made is probably of a somewhat feeble nature. This plant revels in hot sunshine in combination with abundance of moisture at the root during the growing season. —J. C.

2261.—**Watercresses.**—The profit to be made out of half an acre of Watercresses depends on so many circumstances that it would not be safe to estimate; but with a good soil, retentive bottom, and care that the crop, once established, is never stinted in a constant supply of water, could not fail to show a most profitable result. A simple method of spreading the water over your ground will be to bank up the stream at the highest point, then cut V shaped trenches from that point right and left, about 4 in, or 6 in. deep, following every irregularity in the ground in a serpentine manner, always maintaining the same level, and only allowing sufficient fall to induce a gentle flow of water along the entire trench. Success will greatly depend on the careful construction of this trench: a dead level would be fatal, as the points most remote from your water supply would remain dry through absorption, &c., and tapping the trench at intervals to supply the beds below; on the other hand, too great a fall would produce scour in the bottom of the trench, which must be very carefully guarded against. Your beds should be about 3 ft. wide, perfectly level, and following the line of the trench; the outer edge should be lined with slate, driven down to the hard bottom and rising quite 3 in. above the soil, and the points made comparatively water-tight by overlapping and a liberal puddling of clay: this, if effectually carried out, would give a perpetual supply of about 2 in. of water over the surface of the beds, without which, I am of opinion that Watercress growing cannot be made a financial success. Each succeeding bed should be made in the same way, the overflow from above supplying that below. The trench should be tapped at intervals of not less than 6 ft. or so on from bed to bed to the lowest part of your ground. A footway from 12 in. to 18 in. should be left between each bed, which will much more than repay itself in the gathering of your crop and repairing leakages. The indiscriminate mauling that natural Watercress beds are subjected to will at once point out the desirability of having these footways, and not having your beds too wide. I do not know a more generous plant than the Watercress if liberally treated. It delights in shade and plenty of rich manure. I grow it freely under a quickset fence in a natural stream, banked at intervals to produce a normal flow, and occasionally drop at the head-water a spadeful of finely decomposed manure and loam mixed, with a little salt added, which finds its way, through the action of the water, to the whole bed.—WATERCRESS.

2258.—**Planting a Rockery.**—The following are all pretty and interesting species, and should thrive in the situation mentioned:—Sempervivums arachnoideum and Browni, Sedums acre aureum, carneum variegatum, and Lydium, Saxifraga longifolia and the hardy species of Cactus, Opuntias Rafinesquiana and missouriensis. All these should be planted on the upper portion of the rockwork in the hottest and driest positions. Other suitable subjects consist of Androsace sarmentosa, Anemone apennina, Arabis lucida variegata, Lithospermum prostratum, Polygonum vaccinifolium, Saxifraga pyramidalis, Phlox Nelsoni, and Campanulas turbinata and carpatica. In the dampest positions may be planted Ramondia pyrenaica, Gentiana acaulis and verna, and Primulas cortusoides, amœna, denticulata, and cashmeriana.—J. C. B.

2257.—**Orinthogalum arabicum.**—It is difficult to assign a reason for the bulbs not flowering. Try the following treatment. Put the plants in a cold frame, just shielding them against vicissitudes of climate, watering when needed until the foliage dies away. Pot them again in October, and plunge the pots to the rims in a cold frame, allowing them to remain there until the flower spikes appear. This species flowers freely when planted out in the open air.—C.

2263.—**Jonquils and Tulips.**—The Tulips and Jonquils should not have been removed from the ground until the foliage was quite decayed. We fear that you will get but a poor display of flowers next year. Unless you have particular reasons for so doing, there is no need to take up the bulbs at all. If the soil is well prepared for their reception, and the ground around them is not much disturbed by the spade, they will increase in strength, and will flower freely every year. It is, indeed, only in this manner that the true beauty of these spring-flowering bulbs is fully displayed; they should be seen in masses, and then they produce a very pleasing and natural effect If the soil is naturally good, dig it deeply, working in some rich but thoroughly decomposed manure. Plant the bulbs in October, burying them several inches under the surface. Give them an annual top-dressing of manure, applied in the autumn, and allow them to remain undisturbed. Should the natural staple be very sandy, mix with it some good loam; if, on the contrary, of a heavy retentive character, lighten it by the admixture of some leaf-mould, river sand, or wood ashes. —J. C.

2252.—**Hardy Perennials.**—Let me advise "Rustic" to procure some seeds of Primula japonica at once, and sow in a seed-pan to transplant early next spring for flowering. It will be weeks, or perhaps months, in germinating, but is very showy, and quite hardy. Mimulus moschatus Harrisoni is showy and good. Gaillardia picta and Calliopsis philadelphica versicolor nana are not common perennials, but very good.—AMATEUR.

2245.—**Wall Climbers.**—Passiflora princeps, Tacsonia etoniensis, Rhyncospermum jasminoides, and Plumbago capensis, are all suitable subjects for the situation mentioned.—C.

2249.—**Manures.**—Pig manure is one of the most fertilising, but it should be well rotted; in the raw state it is not suited for plants unless it is mixed well with leaf-mould and good earth.—HENRY BROWN.

2266.—**Strength of Manures.**—Fowl manure is about half as strong as guano. My advice is not to dust either guano or fowl manure over the Onions, as some persons do. Mix well with water, so as to form liquid manure, and water at the roots only. This plan is best for Onions, flowers, and Lettuce. Many crops are spoiled by the dusting method.—HENRY BROWN, *Northallerton*.

2274.—**Rose Tree not Growing.**—"Bert" made a mistake in pruning his Rose at the same time as he re-potted it, and leaf-mould is not strong enough; well-decayed stable manure should have been mixed with the loam. "Bert" should remember also that unless the plant has filled the pot with roots it does not require one of larger size. He has probably over-watered the plant. Keep it rather dry, and dress it with decayed manure.—AMATEUR'S ADVISER.

2319.—**Sawdust for Garden.**—Is sawdust of any use in a garden? Would it improve a clayey soil?—CROSSCUT.

2320.—**Liquid Manure.**—I have arranged for the bedroom slops, soap suds, and kitchen slops, to come into a tank in the garden diluted as they are. Can the urine and soap-suds be too powerful? If copperas (sulphate of iron) be used to deodorise, would it impair the manurial value of the liquid?—ELLCEE.

2256.—**Fennel as a Salad.**—It is not the common Fennel that is so much used in Italy, but a variety called Finochio, It is blanched and eaten like Celery, either raw or cooked. Finochio requires a light rich soil, and rather moist situation. Sow from April to July in deep drills 1 ft. apart; cover the seed lightly. Thin out the plants in the rows to 8 in. Earth up when sufficiently large.—OMBU.

2309.—**Digging Potatoes.**—I planted some Mona's Pride Potatoes on the 29th March, and the tops of some of them are about 6 in. above the ground. When might I expect to turn some Potatoes up?—NOVICE. [In the course of a few weeks dig up a root and see for yourself whether you can turn up any Potatoes.]

2310.—**Rats in Vine Border.**—I have a greenhouse with five Vines in it Two of the Vines made a good start, and are looking well, with a good show of Grapes, but turning yellow; while the other three made no growth. On examining the border I found the roots nearly eaten up with rats. The two that made a good start were not much disturbed. The rats have disappeared, and the three Vines are now making a start.—W. M. N. E. [Fill up the rats' holes with soil, and give the border a thorough soaking with water. This will settle the soil round the roots and fill up the holes, when the Vines will probably grow all right. Those Grapes which have turned yellow had better be cut off, as they are useless.]

2311.—**Re-potting Ferns.**—When is the proper time for re-potting Ferns?—NANCY. [The present is a very good time, but a month ago would perhaps have been better.]

2312.—**Draining Pots.**—How should the pieces of pot for drainage be laid? and about how many pieces should be put in? Does it matter what size they are?—NANCY. [Lay one large piece hollow side downwards over the hole in the pot. The rest of the crocks should be broken up to about the size of a threepenny piece, smaller or larger, according to the size of the pot to be drained.]

2313.—**Wild Convolvulus.**—How can I destroy this?—EIRRAH. [Your only true way will be to keep the tops cut off with the hoe immediately they make their appearance. Indeed, if the ground is kept constantly hoed, their shoots will not have a chance of appearing above ground, and the roots will then in time die from want of that support which they can only obtain from leaves and shoots.]

2314.—**Topping French Beans.**—Do French Beans require to have their tops pinched out in the same way as recommended for Scarlet Runners?—A SUBSCRIBER. [It is not at all necessary; but to gain experience top one row and see the difference in the crop.]

2315.—**Asparagus and Lettuce.**—Our Asparagus bed is smothered with Lettuce plants, and we have scarcely any Asparagus. Do the plants interfere with the crop?—W. W. W [The Lettuce plants should have been cleared off before the Asparagus commenced to grow, but probably the bed is worn out.]

2316.—**Cuttings of Oak-leaved Geranium.**—I have a cutting of this plant which was taken last autumn. It has been in a hotbed all the winter, but has since been placed in a window with a westerly aspect. It keeps its green buds, but refuses to send forth shoots or leaves. How ought it be treated?—A BEGINNER. [Pinch off all flower-buds, and the plant will probably grow all right when it gets inured to its present quarters. The sudden change from the hotbed to the window would arrest its growth for a time.]

2317.—**Camellias Out-of-doors.**—In GARDENING of June 5 is an article on this subject; in what part of England, or in what country, is the garden he alludes to? —EASTBOURNE. [In Jersey.]

2318.—**Plants in Heated Frame.**—I have a frame which is heated with 3 ft. of horse manure: some people tell me that I should sink the pots down to the rim; others tell me that I should keep them about 2 in. or 3 in. from the top of the manure, to prevent the snails, etc., from eating the roots. Which is the best way to keep them?—M. P. [You do not say a word as to what plants you are going to put in your frame.]

Plant for Initials or Devices.—*W. D.*—One of the best white plants for the purpose is Cerastium tomentosum. It is best planted in autumn, and it is perfectly hardy.

Insects on Gooseberries.—*Mrs. R., Isleworth.*—The insect is probably that known as the Gooseberry caterpillar. See notes on the subject in recent numbers of GARDENING.

Woodlice in Mushroom-house.—*R. N.*—You may kill a great many by pouring boiling water round the walls at night; and many may be caught by placing slices of Carrot or Potato about the beds, and examining them every morning. A few toads kept in the house will also destroy a great many, and do no harm to the Mushrooms.

When to Water Plants.—*H. B.*—During winter and spring the best time to water plants is early in the morning, but during summer they should be watered in the afternoon.

Potting Auriculas.—*H. B.*—The present is a very good time to pot Auriculas. They should always be potted as soon as they have done blooming.

Remedy for Beetles.—*R. N.*—We are not aware that cats or dogs will eat the paste recommended some time since for killing beetles; but it is, of course, advisable to keep such animals from the spot where the poison is laid.

Rose-leaf.—*Subscriber, Hackney.*—It appears to have been frost-bitten, and afterwards scorched by the sun.

Vesuvius Pelargonium Sports.—*Ici.*—The sport you send was produced several years ago, and is now in commerce; also a white-flowered variety obtained in the same way.

Carnation not Blooming.—*Illawarra.*—Plant it out of-doors in good soil, and lift it in autumn and pot it and place it in a cold frame or window.

Plum Trees and Birds.—*C. E. B.*—You can put a net over the tree, but we do not think birds are likely to injure the crop. Wasps may, when the fruit gets ripe; and then muslin or gauze must be used if you wish to keep them off.

Cucumbers Turning Yellow.—*J. S.*—As soon as you see a fruit with a blossom on the end pinch out the point of the shoot on which it is borne, leaving one leaf past the fruit. You might also fertilise the blossoms, a process which you will find explained in GARDENING a few weeks ago.

Slugs, &c., in Fernery.—*Clifton.*—Petroleum will be neither effective nor safe for watering Ferns, &c., with a view to killing insects. Try the numerous receipts given in answer to queries in GARDENING during the past few weeks; or in Vol. I. you will find abundance of information on the subject.

Cyclamen Bulbs.—*S.*—The crowns of young Cyclamen bulbs when potted should be just seen above the soil.

Laburnum with Different Coloured Flowers.—*C. S.*—The Laburnum often "sports" in the manner you describe.

Procuring Bulbs.—*Clifton.*—The bulbs of Tulips, Anemones, &c., are best procured in September.

Taking Geranium Cuttings.—*Clifton.*—You may put these in any time from now to September. They will strike readily in sandy soil in the open border. Pot when rooted in well-drained pots of sandy soil.

Fuchsia Buds Falling Off.—*John Tib.*—This is sometimes due to dryness at the root, sometimes to over-watering, but generally from want of fresh air. Give plenty of air, shade slightly from the sun, and keep the soil in a moist condition, and all will be well.

Marechal Niel Rose.—*Tarragon.*—This can be procured at any good Rose nursery, such as Paul's, Turner's, &c.

Broccoli Plants.—*G. R.*—Let them stay where they are; what you have been told about their not "heading" till next spring is all nonsense.

Moving Roses, &c.—*Phillipa.*—The Roses will have done blooming by July, and will be starting again into growth. They may then be moved with a fair prospect of success if you do not keep them out of the ground too long, and do not injure the roots. After planting well water them, and apply a mulching of half rotten manure. Tulips, &c., may be taken up with safety, and kept or planted again at once. Cut down the Pansies at once, and they will throw up new growth, and may be moved by the time you name. Chrysanthemums, if not too large, will bear moving well.

Dandelion Salad.—*H. J. V.*—The question you ask has been answered several times lately.

Soil for Valisneria.—*Rev. L. A. B.*—This is an aquatic plant, and will grow without any soil if placed in the water. If you plant it in coarse sand or gravel at the bottom of a tank it will grow freely.

Hyacinth Bulbs.—*H. E. R.*—Plant them out in good soil under a wall or fence. They will be of no more use for pot culture, but if treated as advised, they may throw up a few flowers each year if left undisturbed.

Lobelia Seeds.—*H. E. R.*—If the seed has been washed up by careless watering you had better sprinkle a little dry silver sand or very fine mould over the seed, and then press it down with some flat surface.

Roses Failing.—*Rev. F. N.*—The Roses are covered with brown scale. All you can do is to brush it off now, and next spring prune back the trees, and paint them all over with seal oil.

Cauliflowers in London.—*W. W.*—We have never seen good Cauliflowers grown in London, but there is no reason why yours should not be planted and tried. Mix some soot with the soil, which must be deep and fairly rich. After planting, put a ring of lime around each plant to keep off slugs.

J. A. Gamble.—Kindly observe our rule, viz., ask your questions on separate pieces of paper, and write on one side only.

Coleus.—*H. B., Dulwich.*—See GARDENING, June 5.

A Sub.—We cannot say what the plant sent is, but it is certainly not a Begonia. Send samples to the seedsmen you bought the seed from.

Names of Plants.—*L. E. M.*—The Quamash-root (Camassia esculenta).——*W. R. T.*—Buddleia globosa, belonging to a genus of Scrophulariaceæ.——*W. Inglis.*—Coronilla Emerus.——*J. B.*—Cyrbonium falcatum.——*G. S. N.*—Saxifraga granulata.——*Canonbury.*—The Yellow Day Lily (Hemerocallis flava); a hardy bulb.——*P. A. D.*—Ferns: Lastrea dilatatum and Athyrium Filix fœmina. Flower: Trientalis europæa.——*M. M. C., Hereford.*—I, Narcissus incomparabilis fl.-pl.; 2, N. incomparabilis; 3, Leucojum pulchellum.——*Sep.*—A, Greater Stitchwort (Stellaria Holostea); B, Cerastium Biebersteini; C, Duke of Argyle's Tea Plant (Lycium barbarum.——*S. K.*—Weigelia rosea.

QUERIES.

[We have occasion to again remind our readers that all queries for insertion must be written separately on one side of the paper only, and must be accompanied by the name and address of the writer, with any *nom de plume* he may wish to use. Three questions only at a time can be inserted.]

2319.—**Vinegar Plant.**—I understand that this is a greenhouse plant, and will supply vinegar. Can any one tell me where I can get one, and how it is to be treated for this purpose?—A. B. C.

2320.—**Climbers for Greenhouse.**—I have a small unheated greenhouse, size 4 ft. by 3½ ft., and 7 ft. high, against a north wall, in which I want to grow some climbing plants. Can any reader inform me what will be the most suitable for my purpose requiring the least attention? Would a Vine succeed in such a position?—EAST LONDON.

2321.—**Pot-bound Plants.**—Can any one say why plants become pot-bound? I am told that it is because the limited soil of a pot soon becomes exhausted and the plant throws out fresh rootlets in search of nourishment. Is any means known of supplying plants in pots with sufficient nourishment to prevent this?—M. P.

2322.—**Raising White Thorns.**—Will some one tell me how to raise White Thorns from seed, and how the seedlings should be treated?—J. H.

2323.—**Flies in Rooms.**—An invalid relative is suffering from the number of flies which come into her room. We hear certain plants placed in the window will keep them out. Can any one tell me the names of these plants?—J. L.

2324.—**Summer Pruning Pyramid Fruit Trees.**—Will some one kindly fully explain how and when this is done? Should the leaders be left or shortened back? and should those shoots which are cut back now be further shortened at the winter pruning?—M. H. H.

2325.—**Roses Losing their Buds.**—I have wall Roses, Maréchal Niel (south-west aspect) and Gloire de Dijon (north-west). The buds fall and leaves curl up. No trace of pests except a little cobweb, which is at once removed. Watering with water and soft soap brings to the surface many worms. What remedy? My standard Perpetuals are healthy.—SALOPIAN.

2326.—**Plants for a Greenhouse.**—Can any reader inform me from practical experience the best way of heating a small greenhouse, 7 ft. by 5 ft. 8 in. by 10 ft. in height? Sun never very strong upon it even in summer. I wish to cultivate plants to be in full bloom at Christmas. Also kindly give me names of plants that will be best for the purpose.—TUNBRIDGE.

2327.—**Asparagus near the Sea.**—I have a large piece of ground with a southerly aspect sloping down to the sea. It is thus exposed to the full force of the sun, and also to that of the wind from quarters ranging from south-east to south-west. The soil is deep, the subsoil being old red sandstone, porous. Is it practicable, plenty of manure being at command, to grow Asparagus thereon? and will damage done to the foliage by strong wind produce decay, or, at all events, arrest the development of the roots?—W. B. W.

2328.—**Food for Roses.**—How is calcareous food best applied to out-of-door Roses in a locality where the soil is devoid of that necessity?—R. H. P.

2329.—**Book on Pig-keeping.**—Will any one recommend me a cheap book on pig-keeping—one which gives practical advice to one who is quite ignorant on the subject?—H. CHATE.

2330.—**Sulphur from Greenhouse Flue.**—I have a greenhouse, 30 ft. by 12 ft., heated with 9-in. glazed pipes, and have tried several remedies to stop the sulphur coming through the joints and cracks, but without success. Would any reader kindly inform me what to do without taking them out?—W. B.

2331.—**Failure of Rose Trees.**—I find that a great many of my Rose trees are not coming into leaf this year. They all flowered well last season, but the heavy rains caused a great many of the flowers to rot on the trees. I should be glad if any reader would give me information as to the cause of this, and if there is anything I can do to them. They are bush Roses, principally Cabbage, York and Lancaster, and common red kinds. They were not pruned this year.—NANCY.

2332.—**Club-footed Cabbages.**—I generally raise my own Cabbage plants, but for the last five or six years I was sadly annoyed by having about one half of them club-footed, which came to nothing; but this year, although sown on the very same plot of ground as last year, I have not yet seen one plant so diseased. What can be the reason? I sent to a respectable firm (as usual) for fresh seeds, but being pressed by kind neighbours to spare all, I made shift without sending for more by sowing some two or three year old seed I had in the house. Has the age of the seed anything to do with it?—Y. A.

2333.—**Bouvardias for Bedding.**—Can Bouvardias be grown as bedding-out plants pegged down over a small bed?—WATFORD.

2334.—**Pelargoniums for Show.**—Would any reader who has exhibited regal, single, zonal, and double Pelargoniums, tell me what time to allow between final stopping and show day, and say whether dark take longer than light ones in all classes?—MARIE LEMOINE.

2335.—**Transplanting Violets.**—I have some Czar Violet roots, and wish to make a new bed. I find quantities of runners, but scarcely any rooted. Is it as well to divide the old crowns?—WATFORD.

2336.—**Grubs in New Land.**—I am starting, as a novice, to garden, having this year acquired a good piece of land. The turf that was on the top has been dug in fairly deeply, and my crops are looking pretty well on the whole; but during the last few weeks I have noticed that almost all my seedlings have disappeared, and now my Lettuce, which was looking so well, is withering up. I examined the ground yesterday, and find that it is infested with large grubs, and that they eat off the roots close to the tops, which latter of necessity die. How can I get rid of them?—SEIRIOL.

2337.—**Plantains on Lawns.**—Can any one tell me of any means of destroying plantains on lawns? Arsenic, I am told, will do so, and vitriol, but the latter is not effectual.—C. C. O.

2338.—**Roses not Blooming.**—My Maréchal Niel and Cheshunt Hybrid Roses in a conservatory, south-east aspect, make plenty of wood and leaves, and look healthy, but they do not flower. They are three years old, and have been planted twenty-one months. What is the cause?—C. C. O.

2339.—**Rabbit-proof Plants.**—Will some one tel me the names of a few herbaceous plants, shrubs, &c., which are rabbit-proof?—E. D. T.

2340.—**Romneya Coulteri: Mentzelia ornata**—Will any one inform me how to successfully grow Romneya Coulteri? I cannot get more than about 1 ft. of growth in the season. It is planted out in good soil and in a south aspect. Also Mentzelia ornata, which I cannot get beyond a seedling by various treatments.—W. B.

2341.—**Chemical Manure.**—Can any of your readers kindly tell me how I can easily and without apparatus make a good strong, yet cheap, chemical manure for poor ground? Particulars as to quantity to mix, &c., would be acceptable.—H. MOULTON.

2342.—**Daisies on Lawns.**—About four years ago I converted an old-fashioned garden into a pleasure ground, and had it sown with Grass seeds, intending to make it like a carpet, with short Grass regularly mown. Soon after some Daisies appeared in the Grass, and more in the next year, and now the Daisies have entirely overrun my pleasure ground. What should I do to get rid of them?—E. G.

2343.—**Figs Rotting Off.**—I covered a Fig tree with glass last winter; it has thriven well up to the present, but the Figs invariably rot in the eye when they begin to ripen. I have not watered since the middle of April; I then gave the ground a thorough soaking with spring water. How should I treat it further?—GUERNSEY.

2344.—**Maggots on Holly Leaves.**—Can any one tell me how to destroy a small white maggot which enfolds itself in the tender young leaves of the Holly? Every Holly I have seen is always alike, and there is a always a maggot within every new shoot. It feeds on the new leaves, curls them up, sticks them together, and sadly interferes with the annual growth of this truly English evergreen shrub.—R., *Hampstead.*

2345.—**Pigeon Manure for Plants.**—Can any one tell me at what strength this may be used for plants?—C. E. B.

2346.—**Barked Apple Trees.**—Some of my young Apple trees are entirely barked a yard up the stem. What will be the consequence, and how can it be alleviated?—APPLE LOVER.

BEES.

Are Bees Profitable.—Last year I kept bees about five minutes' walk from King's Cross, and about one mile from the Regent's Park. They are undoubtedly profitable in the hands of an enthusiast—one who loves his bees and cares for them as he would for any pet; at least so I found them even last year, which was admittedly the worst for 40 years or more. Begin with a swarm in May or June in a bar-frame hive, and thoroughly read up the subject and grasp its principles from some good modern manual. But do not be misled by reports of enormous profits derived from bee-keeping put forth by some writers. Under exceptional circumstances, I have no doubt very large profits are obtained; but these favourable circumstances seldom fall to the lot of the tyro in any pursuit.—APIARIAN.

—— Bees can be and are kept, not only in the neighbourhood of London, but actually *in* London. At the show of the British Bee Keepers' Association at South Kensington last July was exhibited a super filled by bees kept in the Strand. Of course they were fed; but now the squares, the embankments, some churchyards, and other open spaces, are kept as gardens, bees would probably get their own living during the summer; and at the West End, where they had access to the Lime trees and the Clover in the parks, would perhaps store a little honey. Bees are kept in Lincoln's Inn Fields, in Camden Square, and in Newington Butts. A working cabinet-maker, living in Trafalgar Street, Walworth, told me when I met him at a bee show that he had that year taken 30 lb. of honey from his hive, and sold it to his mates at 1s. 6d. per

pound). I keep them here (Vauxhall); and a little further out—as Stoke Newington, Clapham, Brixton, &c.—many are kept. The Baroness Burdett Coutts, president of the British Bee-Keepers' Association, keeps bees at Highgate also. My personal experience is that bees in the immediate neighbourhood of London will, with a little assistance in early spring, get their living; and a few miles out, say a radius of four miles, more or less, from St. Paul's, would, in good years, bring in a little profit.—APIS.

A GARDEN HAMMOCK.

A HAMMOCK well "triced up" forms an excellent resting-place on board ship, more especially in a heavy gale, but it is vastly inferior to the hammock (hamaca) of South and Central America and the West Indies, which, in the opinion of those who have tried both, is a more perfect lounge than any sofa that has yet been made. These hammocks, whether made of palmetto fibre or of cotton—they are exported in large numbers from Manchester—should be fully 11 ft. from "clew to clew," and when spread out laterally should have a width of quite 6 ft. Two good-sized trees, about 10 ft. apart, should be chosen, from which to suspend the hammock; in each of these, at a height of 6 ft. from the ground, fix a stout screw-hook, having an iron thimble on it, round which the "lanyards" or ropes should be passed—this thimble preventing the rope being cut by the hook. Each end of the hammock is then suspended, and it is then lowered down until it is

A Garden Hammock.

some 16 in. from the ground. Spread it well out sidewise, place a pillow in it for your head, and the veritable hammock of tropical America is ready for occupation. It is usual to have it lowered to within 18 in. from the ground, as you are thus enabled with a touch of the foot to set it swinging when you please. Hooks should always be used, as they render it possible to bring everything within doors at a moment's notice. A. L. T.

POULTRY.

Green Food for Poultry.—I have always found great difficulty in getting a constant supply of green food, but now I grow Oats: they grow 3 in. or 4 in. high in a few days, can be grown on flannel in a kitchen in winter, and are juicy and greatly relished by the fowls. I take a handful and cut into ¼ in. pieces with a pair of scissors, the fowls tumbling over my feet in their eagerness to pick it up. Of course I offer this hint to keepers of fowls in town. Mine are in a paved stable yard. I have, including chickens, about 40, and my yard has a total area of about 200 square yards. Will some one say if this number when grown up will be too great for the space? They have, of course, plenty of amusement scratching on the dunghill and in the stables.—APIS.

Food for Poultry.—Can any reader inform me whether worms collected by throwing lime and water on the Grass, garden beds, &c., are suitable and harmless food for ducklings and other poultry?—L. N. B.

Disease in Fowls.—I have had several hens which gradually drooped and then died. When examined, they had scarcely any flesh on the breast. Could any reader inform me as to the cause, and if there is a cure? I feed them chiefly on Maize, and they have a run of six acres. I have had two hens die in the same manner as described by "Amateur," in GARDENING of May 29th.—G. N.

Featherless Fowls.—Propably the cause of "F. R. C's." hens losing their back and tail feathers is an awkward or too heavy cock, in which case he will often strip the backs of the hens of their feathers, and sometimes take skin and all off. The eggs are in no way affected.—BELLINI.

Fowls with Dark Combs.—The combs of fowls often turn a dark colour after laying for several months without ceasing, also from too close sitting. The cause is due to exhaustion. Feed the fowls well and give them animal food, worms, &c., and they will be all right.—BELLINI.

Young Ducklings.—I would be glad if any one could inform me what breed of ducks would be the best to raise for the market with a view to profit; also, if it is possible to purchase young broods in quantities, and if so, where?—I. T. B.

HOME PETS.

Canaries Unhealthy.—A couple of my canaries hatched out, but the young died at a fortnight old through being insufficiently fed. A few days before they died the cock was taken ill. I took him away and kept him in a cage by himself. He would sit in a heap close on the perch, feathers ruffled, tail and wings drooping, and appeared sleepy. Last Sunday I gave two drops of castor oil. On Monday a warm bath; in the evening repeated oil; Tuesday repeated bath; Friday put him back to the hen. He is rather livelier, but still looks very ruffled and mopish. After taking the cock away, the hen became unwell, the breathing very short and quick; the whole body works, and the tail jerks at every breath and the feathers ruffled. On Saturday I found she made a noise in breathing, like a small watch ticking. As they are both together I have put three drops of sweet nitre in their water the last two mornings. I have another couple, just building for the first time, but am afraid they will do no good. The hen sits with stomach resting on the perch, and very ruffled and the breathing short. The diet for all is Rape and Canary seed, with egg and bread. If anyone can give me any assistance I shall esteem it a great favour.—E. UNDERWOOD.

Breeding Canaries.—I have a few canaries, and some of them are continually making a noise with their bills. Also I have had one hen that sat well upon four eggs for a week, and then gave up sitting; and another that sat three days and gave up. Can some experienced breeder tell me the cure for such birds? The hens are both two years old.—S. TURNER.

Lice in Canaries.—Infuse Tobacco in hot water, and with this decoction thoroughly scrub the cage, wires, perches, seed troughs, and every part. Let it dry before putting back the birds. Repeat once or twice, and again, as prevention, at intervals of a few months, and you will never have an insect in your cage. It is unfailing.—F.

Peacocks.—Will any one give me information about Peacocks, as we are anxious to keep one? What kind of food would it require, and what kind of shelter at night? Would it be likely to peck the family and the dog, or could we make a pet of it? Would it injure the garden by scratching up the earth? Would it stray from the garden, which is a pretty large one, but not enclosed all round?—E. R.

Worms in Dogs.—Give as much Areca Nut powder as will lie on a shilling, made into a pill, with butter, at night, and the following morning a tablespoonful of castor oil. Carbolic acid is not a safe remedy for the skin disease. Try an ointment of petroleum made by Foulger & Co., 133, St. George Street, E.—C. B.

Starlings Talking.—Will any one inform me whether female starlings talk, as well as male?—A. REID.

THE HOUSEHOLD.

COOKING SPINACH.

THIS excellent vegetable forms a good accompaniment to meat when plainly boiled in plenty of water, with all the moisture carefully pressed out of it; it should then be chopped small, put into a clean saucepan with a slice of fresh butter, and stirred until it is well mixed and very hot; it should then be placed smoothly in a dish, marked in dice, and served.

Puree of Spinach.—Boil it until quite tender, chop it, and rub it through a sieve with great care; put it into a saucepan with a small lump of butter and pepper and salt; stir this mixture well, and serve it hot. A dish of mutton or veal cutlets, or fried pieces of chicken, may be arranged like a crown on a dish with this purée in the middle, or there may be poached eggs or little rissoles placed upon the purée. Any of these form a pretty luncheon or supper dish.

Mould of Spinach.—Boil the Spinach, and after it has been squeezed and chopped, stir it over a moderate fire until it is very dry; moisten it with as much thick rich gravy as will flavour it well, and turn it over and stew it fast until it is again dry; then press it into a hot mould of handsome form, turn it into a dish, and serve it quickly; 2 oz. or 3 oz. of fresh butter may be used as a substitute for gravy. A perforated tin shape is the best for moulding Spinach, but one of earthenware, slightly buttered, answers perfectly well.

Spinach a la Française.—When boiled and chopped, put the Spinach into a pan with a tablespoonful of pounded sugar, a little grated nutmeg, 6 oz. of fresh butter, and a tablespoonful of flour; when this mixture has been stirred over the fire for some time remove it, and add a tablespoonful of thick cream; dish it, decorating it with fried croutons — these are small pieces of bread, cut out with a pastry cutter, and delicately fried in butter. Leaves of light pastry (baked) may be used instead.

Stewed Endive.—Wash in plenty of water three good-sized heads of Endive, and simmer gently for ten minutes in one quart of water and one teaspoonful of salt; strain the water off thoroughly, add one teaspoonful of cream or milk, 1 oz. of butter, and a small pinch of Cayenne pepper; shake the saucepan about until the butter dissolves. Serve, place the Endive on to a very hot dish, and pour the sauce over.—J. BAKER.

COVENT GARDEN MARKET.

WHOLESALE PRICES.

Cut Flowers.—*Per dozen bunches.*—Anemone, 2s to 6s; Azalea, 4s to 9s; Cineraria, 6s to 12s; Ferns (various), 3s to 9s; Heliotrope, 6s; Lily of the Valley, 4s to 12s; Lilac, 2s to 8s; Mignonette, 4s to 9s; Narcissus, 6s to 12s; Pelargoniums (zonal), 3s to 6s; Pelargoniums (large flower), 6s to 12s; (double), 6s to 12s; (Rose-scented leaf), 6s; Spiræas, 6s to 12s; Tropæolums, 1s to 3s; Tulips, 4s to 9s: Violets (blue), 1s to 2s.—*Per dozen flowers.*—Abutilon, 4d to 6d; Arum Lilies, 3s; Tree Carnations, 1s 6d to 3s; Eucharis, 4s to 6s; Gardenias, 2s to 8s; Roses, 1s 6d to 6s.—*Per dozen sprays or trusses.*—Bouvardias, 1s 6d to 3s; Fuchsias, 2s to 4s; Primulas (double), 9d to 1s; Stephanotis, 2s 6d to 4s.

Plants in Pots.—*Per doz.*—Arum Lilies, 9s to 12s; Adiantum cuneatum (ordinary), 6s to 18s; Begonias (flowering), 6s to 12s; Begonias (fine-foliaged), 6s to 12s; Bouvardias, 12s to 18s; Cineraria, 4s to 12s; Daphne indica, 4s to 6s; Dracæna (green-leaved kinds), 12s to 30s; Euonymus, 4s to 12s; Euonymus (variegated), 6s to 18s; Ferns (greenhouse and stove, various), 6s to 18s; Ficus elastica, 18s to 60s; Fuchsias, 6s to 12s; Gardenias, 24s to 36s; Lily of the Valley, 12s to 24s; Mignonette, 6s to 9s; Nasturtium, 3s to 6s; Palms (small), 18s to 60s; Pelargoniums (fancy), 9s to 24s; Pelargoniums (scarlet), 4s to 9s; Pelargoniums (double), 6s to 12s; Roses (hybrid perpetual), 12s to 24s; Spiræa japonica, 6s to 18s; Selaginellas, 3s to 4s; Virginian Creepers, 6s.—*Per pair.*—Maiden-hair Ferns (large), 4s to 7s; Palms (large), 15s to 42s; Amaryllis, 1s 6d to 3s each.

Fruit.—Apples (culinary), per bushel and barrel, 9s to 30s; Cobs and Filberts, per 100 lb, 120s; Grapes (English hothouse), per lb, 2s to 6s; Lemons, per box, 30s to 35s; Oranges (various kinds), per 100, 8s to 16s; Pomeloes, per dozen, 3s to 6s; Pine-apples (St. Michaels), each, 5s to 15s; Pine-apples (English hothouse), per lb, 1s 6d to 2s; Strawberries (early forced), per oz, 4d to 6d.

Vegetables.—*Per* 100.—Asparagus, 3s to 5s; French Beans, 9d to 1s. *Per dozen bunches.*—Carrots (outdoor), 4s to 5s; Watercress, 9d to 1s; Leeks, 1s 6d to 3s; Mint, 4s to 6s; Parsley, 6s; Turnips, 1s to 1s 9d; Radishes, 9d to 1s; Herbs, 2d to 6d. *Per doz. punnets.*—Cress, Mustard or small salad, 2s. *Per dozen.*—Cucumbers, 4s to 7s; Endive, 2s to 3s; Lettuce, 9d to 1s. *Per bundle.*—Horseradish, 3s to 6s. *Per lb.*—Shallots and Garlic, 6d; New Potatoes, 2d to 5d. Broccoli (Cornish) per crate, 10s to 18s; Broccoli (Sprouting), per bushel, 2s 6d; Saveys, per score, 5s; Chervil, per punnet, 3d; Corn Salad, per half-sieve, 2s; Mushrooms, per pottle, 1s 3d to 1s 9d; Potatoes (general store, round kinds), per ton, 100s to 200s; Kidney, per ton, 120s to 180s; Parsnips, per tally, 5s to 7s; Rhubarb (per dozen bundles), 2s to 3s; Spinach, per half-bushel, 2s 6d; Tarragon, per bunch, 6d.

THE GLOBE-FLOWERS.

FEW plants are more desirable for our gardens than those known by the name of Trollius, or Globe-flowers. All the species, though varying considerably in height, are of compact habit. With them such a thing as stakes, or other modes of support, need never be resorted to. They carry their own golden globes with an independence that constitutes by no means a small portion of their charm. They may be grown in beds, borders, on lawns, by the side of ponds or streams, and any one not possessing a garden may grow them well enough in deep pots; and grand they are, too, in early spring when in full bloom in the greenhouse or window. They must, of course, be grown out-of-doors till they show signs of flowering. Prior to giving an outline of the more distinct species of Trollius at present in cultivation, it will be as well to notice some of those characteristics which are common to all the species, and thus in some measure economise space and avoid unnecessary repetition. In the first place, they are all of a dense habit of growth, the foliage and flowers rising from an underground crown, which possesses no rambling proclivities—a failing which mars the value of many an otherwise good herba-

GROUP OF GLOBE-FLOWERS (TROLLIUS).

ceous plant. The roots are numerous and deep searching, especially in a border where perfect drainage removes the water-level to a considerable depth, a character which, though not absolutely essential in this case, should form an important feature in all well-made herbaceous borders. The flowers present considerable variation in colour, from a pale yellow to deep golden, almost bordering on vermilion. All the species are spring or summer bloomers, and are at their best in April, May, and June. Occasionally in old-established plants a few autumnal flowers are developed in September and October, but these depend alike on the season and the strength of the plant itself. As regards propagation, they may be most readily increased by division of the root, an operation which should be performed either in September or in March; of the two the former is the best time, as the plants have then an opportunity, during the remaining portion of the autumn, of making fresh roots and thoroughly repairing the damages unavoidable in the operation before the dry early summer sets in. When divided in March, a few dry days, accompanied by sunshine, is sure to find the foliage uncomfortably prostrate on the ground, and the blossoms are equally certain to be puny and short-lived. Besides root-division, they may also be propagated by seeds. These, in vigorous well-established plants are produced freely, and generally retain, with marked persistency, the specific characters. It is to be noted, however, that they rarely vegetate the same year that they are sown, but come up vigorously the following spring, and, if carefully attended to, will make fine flowering plants the second season after vegetating; they will not, however, attain their full development until the fourth year or even later. They grow freely in any soil, are partial to a good stiff loam overlying a cool moist subsoil, but, if cultivated in a dry situation, should have a good supply of manure, not only to act as a stimulant, but as mechanical and moisture-retaining element in the soil; for, be it remembered, that the mountain meadows they affect are almost invariably supplied with cool water springs below, which enable the plants to withstand the burning heat of an uninterrupted day's sunshine without showing, by their flaccid leaves, any indication of exhaustion. T. europæus (the Mountain Globe-flower) is the native species with which we are all familiar; its height is about 15 in.; the flowers are of a lemon-yellow colour, forming a perfectly globular flower from 1 in. to 2 in. in diameter. This plant is of common occurrence throughout the upland meadows of Europe, and by no means an especial native of Britain alone. T. asiaticus has much more divided leaves, also distinguished by their bronzy-green colour; the flowers are similar in size to those of the last species, but of a golden-yellow not globular, the sepals, as they reach maturity, expanding. When growing vigorously it attains a height of 18 in.; it flowers in the early part of May and rarely perfects its seeds, but is readily increased by root division. It is a native of Siberia. T. albus is considered by some as a mere variation of T. europæus; occasionally met with under the title of T. pumilus. The flowers are of a pale-lemon colour, but not white, as the specific name would indicate. They, however, are dwarf in stature as well as small in development. The plant—whether known by the "white" or "dwarf" titles, is especially fond of peat soil, more, perhaps, than any other species of the genus—is exceedingly compact and distinct in the arrangement of its leaves. These, like its blossoms, are scarcely half the size of the common European species. T. dauricus is distinguished from the foregoing by its gigantic growth, both in respect of plant development and bloom. Its leaves are large, much divided, of a deep olive green, and supported on long footstalks. The flowers are large, lemon-coloured, the sepals overlapping one another in a globose form. It is a native of Dahuria, and is a most desirable plant. It seeds freely, and may by this means be readily increased perfectly true to its type. In heavy soil, which appears to be admirably adapted to the requirements of the genus, it attains the height of 3 ft. or more, and is identical with the species known by the title of T. giganteus and T. Demayanus. T. napellifolius is a handsome strong-growing species; the flower globose, deep yellow, bordering upon orange, more than 2 in. in diameter. It is a native of Central Europe, where, on the slopes of the Carpathian Mountains, it forms a very conspicuous object; and in our herbaceous borders, it carries off the palm as unquestionably the most showy of the genus. T. sinensis is a very distinct plant; it is a native of Japan and China. The flower-stems attain a height of 2 ft. or 3 ft. The flowers are of a deep yellow, the sepals partially expanded. It blooms in month of July, and, in this respect, bears some affinity to the American variety of the Asiatic Globe-flower, to which it is in some degree related. Besides the foregoing, we have T. altaicus, T. caucasicus, T. intermedius, T. tauricus, and T. medius, all of which bear a very close relationship to either the European or Asiatic forms. So slight, indeed, is the difference, that in the species above enumerated, the ordinary cultivator will find all that is required, so far as the genus can supply, towards the decoration of the early summer borders; and with that selection he will not be disappointed.

A Carrot Basket.—A very pretty hanging basket can be made from 4 in. or 5 in. of the top or crown part of a large Carrot. The inner portion of this upper end of the Carrot is to be removed with a knife, leaving a shell about ½ in. thick. Three or four cords are fastened to the rim, and the basket is ready to hang up at a window. The cavity of the basket is to be kept well filled with water, and care taken that it does not become dry. After a while the Carrot will start into growth, and as the delicate, finely divided leaves appear, they will turn upward on all sides, and soon cover the little basket, with here and there the orange colour of the Carrot showing through with good effect. Should the leaves need training to arrange them satisfactorily around the basket, it may be easily done by means of a thread passed around them; or, a bent pin stuck into the Carrot may be used to hold a leaf in place.—*American Agriculturist.*

ROSES.

THE BEST ROSES FOR INDOOR CULTURE.

ROSES out-of-doors in June and July, all must admit, are unsurpassed in loveliness; but some of the best Teas and other varieties produced in spring under glass are equally beautiful. By "under glass" I mean when they are grown on the extension system—that is, trained against walls and up rafters, pillars, &c., when they produce blooms, not by the dozen, as when in pots, but by the hundred or thousand. We grow a good many pillar and wall Roses, and we have lately been cutting large quantities of fine buds and blooms from them. All Tea Roses succeed well under glass, but some bloom much freer than others. The best single Rose for clothing a pillar, wall, or any other extensive bare place under glass, is Gloire de Dijon; the blooms of this variety, although very pretty, are not so attractive, perhaps, as those of some others, but the length of time during which the plant remains in flower, and the succession of bloom which it gives in twelve months, is perfectly astonishing. As is now pretty well known, the blooms are very globular in shape, and a delicate fawn colour, shaded with salmon. This variety grows and blooms in any half-shaded position equally as well as any other variety will do in the best of situations. Maréchal Niel is another magnificent Rose under glass in spring, and if it only produced its flowers for an equal length of time in succession, as Gloire de Dijon, it would, in my opinion, be more valuable than all the other Roses in cultivation put together. When in bloom it is simply superb; but it does not remain in flower very long: our best plants produce from 400 to 700 blooms during April and a little while in May; then they are over for another nine or ten months. This is the only thing that can be said against this Rose, and that is not sufficient to deter any one from cultivating it; for if it only bloomed one week in the fifty-two, that would amply repay all the trouble that could be bestowed on it. The flowers, which are deep yellow, are very full in the centre, large when fully opened, exquisite in the bud state, and most deliciously fragrant.

Céline Forestier, a Rose strongly recommended by many, is with us useless under glass. It has grown freely enough, and has made abundance of healthy wood; but we get no flowers; nor have we seen it bloom well anywhere. So we place a black mark against it. Madame Falcot is a splendid Rose in the bud state. Like most other Tea Roses, it is very poor when fully open; but, leaving this objection out of the question, it is worth growing in quantity on account of the great value of its buds. They are deep orange, or I might say bronze-orange, in colour, and they are produced freely both on small and large plants. Niphetos is a favourite Tea Rose of ours under glass, as it blooms so freely, and produces its fine large creamy-white coloured buds and blossoms in such long succession. We would include it in the best half-dozen Roses which could be named for cultivating under glass. Devoniensis stands high in the list when the quality of the bloom only is taken into consideration; but, as regards number or free-blooming, as a rule it is simply "nowhere," and therefore it is not advisable to grow it, unless where space is unlimited. Cheshunt Hybrid is good, although not the best; but it is worth growing on account of its bright cherry-carmine colour. Belle Lyonaise is another fine climbing Rose, with beautiful canary-coloured flowers, deeply tinted with salmon. We find it better than Cheshunt Hybrid, inasmuch as it blooms freer and larger. Marie Van Houtte is also a magnificent Rose for indoor culture, and one which should be included in all good collections. Bouquet d'Or, Lamarque, and Solfaterre belong to the same Noisette section as Céline Forestier; but they all are much superior to the latter, and are well worthy of cultivation.

Roses under glass do best under much the same kind of treatment with regard to soil, &c., as that under which they succeed so well out-of-doors. Good loam, plenty of manure, and abundance of water at the root, consti-

tute their chief requirements. As to planting, that may be done at any time, provided the plants are in pots; otherwise spring is the best time to plant. A good bed or station should be made for them. The extent of rooting space is not of so much importance as having what is done done well. A good plant may be grown in a hole not more than 2 ft. square. Plenty of drainage should be placed at the bottom, and above that the soil should be rammed down firmly. In planting, the roots should be kept near the surface, and they should not be broken or much disturbed. Until growth has freely commenced water must be sparingly applied, but after that never stint the supply—a rule which should be closely adhered to, not only when the plants are in full growth, but also when they are at rest or growing little or none. This is one of the chief secrets of successful Rose culture under glass. Directions as to training must be left to those who have charge of the plants, as they know best what is wanted to be covered; but this much may be said—that the shoots should never be trained on the top of one another, and the greater the distance between them, reasonably speaking, the better they will succeed. The pruning of all Tea Roses should merely consist in thinning out the weakest of the shoots, and cutting in to keep the plant within bounds. Green fly is about the only insect to which Roses under glass are subject. It is particularly fond of attacking the points of the young shoots and bloom-buds, and should be cleared off them by close syringing before the blooms open; afterwards syringe them off as they appear, for the plants while in bloom cannot be syringed without injuring the flowers. C.

VEGETABLES.

Beans for Exhibition.—In gathering these care must be taken to have all the pods as nearly as possible the same length and age. They should be full grown, but young and brittle, choosing only straight handsome pods for the purpose. If enough cannot be got at one picking, some may be gathered two or three days previous to their being wanted, and if their stalks be inserted in shallow saucers of water and kept in a cool place, they will keep perfectly fresh and green. If required to be sent any distance previously to being exhibited, they may be kept fresh by packing them in tin boxes between layers of damp Moss, Spinach, or Ivy leaves. During summer, leaves of the Ice-plant answer well as a packing material.

Sticking Scarlet Runners.—Where procurable, common Pea-sticks are best adapted for Kidney Beans, but they require to be rather larger and stronger than for Peas; for unless firmly sticked, they are apt to suffer during rough windy weather. Where, however, such sticks are not obtainable, stout poles, 7 ft. or 8 ft. long, may be used, placing them firmly in the ground at intervals of 12 ft. or 14 ft. apart along each side of the row. Slender sticks cut the same length as the distance the poles are apart may then be tied lengthways along the poles 1 ft. or 1½ ft. apart; the plants will twine firmly round these, and thus support themselves.

Broccoli for Exhibition.—When Broccoli is required for exhibition, small plantations should be made in different situations, in order to make sure of having them in at the required time. For this purpose large compact heads are indispensable, though it is better to have them a little small and close than large and open. Trenches are sometimes dug for the plants, and it is a good system where time can be spared. The trenches should be dug 2 ft. wide and two spits deep; the top spit being taken out and laid on each side, then a good thick coat of fresh horse droppings, or rotten manure thrown in the trench, to be turned in and well incorporated with the second spit. The plants may then be put in, and as they grow the soil that was taken out of the trench may be put back round the stems of the plants and trodden in firmly. Good soakings of manure may be given them when the soil is dry, but after the heads are once formed it must be discontinued, or it will cause the flower to open. In cutting, the whitest and firmest heads should be selected, and the more they resemble each other in size and appearance the better; they should never be trimmed until they are going to be put on the exhibition table, and then not so severely as is often done. If it be necessary to cut the heads some time previous to their being wanted, the best way is to divide them with 5 in. or 6 in. of stem and stand them in shallow pans filled with cold water and put in a cool place. The leaves should be tied over the flower, and if an occasional sprinkling overhead be given them, it will help to keep them fresh. This will be found better than pulling up the roots and hanging them up in sheds and similar places.

Summer Lettuce.—Towards the end of June and through July sow Lettuce when possible on the north side of a wall, and thin the plants out according to the size of the kinds grown; 8 in. apart will be sufficient for Tom Thumb Cabbage Lettuce, whilst the larger kinds of Cos and Cabbage will require 10 in. or 1 ft. Sow in drills, as it gives facilities for frequently stirring the soil with the hoe. The thinnings may be planted elsewhere; but if the season be hot and dry, those not transplanted will probably be most satisfactory. When hot dry weather sets in, mulch with rotten manure, if possible, between the rows, laying it nearly up to the plants. A very great thickness will not be necessary; 2 in. or 3 in. at the most will be sufficient. This mulching saves a deal of labour in watering in a dry summer. In fact, without mulching, on some soils watering is worse than useless; it encourages, during the time the effect of the water remains, the production of fibres near the surface, and if the water be neglected for even a short time these fibres perish. Far better will it be on hot soils, if mulching cannot be resorted to, to deepen the soil in every possible way; keep the surface loose by frequent hoeing, and discard the waterpot altogether, unless a regular and constant supply can be given. But when the plants are mulched, a watering once a week or so washes the soluble portions of the manure down to the roots, and pushes on the plants rapidly.

Planting Broccoli.—Though June is the month in which most gardeners try to get their plantations of Broccoli finished, yet it is frequently July before the work is done. Plants put out in August will make nice heads, but the sooner the planting is done after the middle of June the better. Though planting early ensures the finest plants and largest heads, the time of sowing or planting does not materially affect the plants as regards the time they come into use. Though it is by no means an unusual thing to see nice little heads of Broccoli in cottagers' gardens where the soil is seldom turned over more than a spade's depth, and not over liberally manured, yet the plant likes a deep and rich soil. If practicable, the ground should be trenched two or three spades deep, or at least double-digged. When there is not time for doing either of these, then the ground must be dug over a spade deep only, taking care to break the soil up thoroughly, as deeply as a good spade will do it, and working in some well-decayed manure at the same time—the soil being broken up well in the trench, and the surface a little rough. Planting should be proceeded with as soon as the digging is finished. If the planting be done in June or July, from 2½ ft. to 3 ft. must be allowed between the plants; if deferred till August they need not be allowed so much room. If the weather be dry, the seed-bed or that from which the plants are taken should be watered well the night before, to soften the soil. The holes to receive the plants should always be made sufficiently large to admit of their being easily put in without breaking their roots. "Buttoned" and stunted plants are in many cases caused by bad planting. They are put in with broken and mutilated roots; and those that have a tap-root often have it bent double in getting it into the hole, and, instead of the point being at the bottom of the hole, it will be sticking up above the surface. No one should wait a very long time for wet weather in which to plant Broccoli: it is better to get the planting done, and water well once or twice, and the plants will then do till rain comes. When the plants are fairly established and have grown a little, they must be earthed up with the hoe, which will prevent the wind from twisting them about and disturbing their young roots.

Raising Mushrooms.—On looking over the "British Magazine" for 1760, I found the following quick method of raising Mushrooms, which may interest some of your readers. "Method to raise Champignons practised at Metz.—In a cellar, at a distance of 3 ft. or 4 ft. from the wall, raise a bed of horse, mule, or pigeon manure well mixed together. The bed must neither be flat nor raised in the middle, like the back of a trunk, but made sloping, and covered with ½ in. in depth of earth or mould. This bed, being watered from time to time, will produce Champignons for four years successively. The production of them will be hastened by watering the bed with warm water, and throwing into it the pickings of the same fruit. If you sow the grain that is found towards the foot of the Champignons among some cakes of what is called muckmould, the bed will produce the fruit on the third day after sowing; but the manure must be from horses fed with Corn. Muckmould is a kind of putrid horse manure, speckled with white spots and filaments. It may be made in any stable or shed exposed to the south by watering the mass from time to time with horse urine or warm water."—Hortus.

Mushrooms in Cocoa-fibre.—I wish to relate some experience I have earned in the growth of Mushrooms. Early in the spring I had a two-light frame made up with very light manure—in fact, it was little better than straw, there being almost next to no droppings amongst it. Under one light I had the manure covered with ordinary garden soil, and under the other it was covered with Cocoa-refuse to a depth of 5 in. or 6 in.; the frame was filled with pot plants, slightly plunged but not crowded. The whole was regularly watered and exposed to the sun and air. To my surprise, the Cocoa-refuse is one mass of Mushroom spawn, the Mushrooms coming up in clusters all over the bed in a way that astonishes all beholders; they are as pure a pink and white as you can imagine, and grow exactly like those gathered from an August pasture. The roots or fibres seem to revel in the refuse, and to extend some 3 in. or 4 in. in diameter in the refuse, but not deep down; in fact, the spawn seems confined to the refuse. Under the light where the soil is not one Mushroom is to be seen, nor is there a vestige of spawn. This is all unaccountable to me. Can any of your readers who are more learned in these matters than I am throw any light on the subject?—W. P. D.

An Asparagus Bed.—If any farmer were to read the directions given in the older works for making an Asparagus bed, he would at once conclude that Asparagus was a luxury not for him. A pit was to be dug, and oyster shells or brick-bats put in for a foundation; then numerous loads of manure were to be buried by trenching; and so much circumstance attended it that ordinary persons were frightened at the labour and expense. But of late years (says the *American Agriculturist*) our garden books do not copy English methods, and in nothing is the change for the better seen more distinctly than in Asparagus culture. Any one who can set out Tomatoes can plant an Asparagus bed. The first thing is to get the plants; good strong plants a year old may be had of most seedsmen. If one prefers it he can raise the plants, but those who buy them will gain a year. For family use the distance of planting varies. Where there is plenty of room, rows 3 ft. apart, with the plants 1 ft. distant in the row, is better than nearer. Choose good garden soil, and set the plants so that the crowns will be at least 4 in. below the general surface. At planting, give each root a spadeful of fine manure or compost, and trust to annual manurings to keep the plants in a productive condition, instead of the old method of manuring once for all future time. During the season keep the bed well cared for, the soil loose and free from weeds. As a general thing, the plants should grow two years before cutting.

Endive Running to Seed.—To avoid this at the present early season the seed should be always sown in a dung frame, grown rapidly, and planted out on the top of a heap of leaf-mould or dung. Even now Endive should be sown in a frame, the seed germinated as quickly as possible, and planted out as soon as ready on ground made moist with plenty of manure. Endive may be got up easily by simply sowing in heat, and pricking out and planting when

ready, as is done with early Celery. Thus treated, not 5 per cent. will run to seed.—C.

The Best Frame Potato.—I have tried a good many sorts of Potatoes for early crops under glass, but as yet have found nothing to equal the old Ashleaf Kidney. We have at present a long range of pits fit for lifting of a selected strain of the old true kind, and it is impossible to detect the slightest variation in a single plant.—J. G. L.

Late-sown Parsley.—Where large quantities of Parsley are required at this season, it is a good plan to make a late sowing—say between the middle and end of July. A large proportion of all biennials sown after midsummer fail to flower the following season, and in the case of Parsley it is a decided advantage to have a part of the crop in this condition, as it permits the supply to be kept up without cutting too closely the young spring-sown crop.—E. H.

Early Turnips.—For early Turnips I prefer Snowball and White Strap-leaf. When sown in succession they come in fine and tender all the season; and for late use a good breadth sown in August will keep up a supply during winter.—J. M.

GENTIANS.

THESE are considered supreme among Alpine flowers for their beautiful hues. Among the Rock Speedwells, the Gromwells, the Harebells, and many other families, we have numerous lovely blue and blue-purple flowers; but it is among the Gentians that we find blue flowers that startle us with the depth and brilliancy of their colour, and that sparkle in the early summer Grass as glowworms do in the dark wood. The Gentians are mostly mountain flowers, or of those open heaths, upland pastures, and wide-spreading bogs which in northern lands so often enjoy the fresh mountain air and its coolness. Occasionally they haunt the fringes of the stream, as in the case of the Bavarian Gentian, which is so exquisitely beautiful beside many thousand Alpine meadow-rills in Europe, and the nobler, if somewhat less vivid-coloured, Gentians which adorn the rocks and banks by the great North American rivers and streams. Usually they are dwarf in stature and compact in growth, but one very common species on the Alps, Gentiana lutea, may be classed with the most vigorous perennials. It, however, has not the charm of colour; but the lovely American fringed Gentians, while resembling our brightest European kinds in this respect, surpass them in size of blossoms, and spread forth into sturdy spreading bushes laden with fringed vase-shaped flowers. In a wild state Gentians do not by any means require peculiar conditions as to position or altitude. The same kinds frequently abound on high snow-clad ranges, hoary in much of their Gentian-haunted surface until far into the early summer, and hills not more frequently covered with snow than the uplands of Britain; generally, however, they love meadows and moisture rather than the rocks or sands, and they crowd most of all into those wide Alpine pastures where they have to struggle for standing room with sturdy little Primroses and silvery Cudweeds and large Violets that sometimes form an iridescent turf standing clear above their tiny leaves. In our gardens it is quite possible to enjoy the beauty of the Gentians without experiencing much trouble, though these plants are as yet but little grown. They may, from the point of view of culture in our gardens, be classed in two sections—the first, of strong easily-grown kinds, suitable for borders; and the second, of the dwarfer kinds, which should be grown on the rock gardens, or in borders or beds devoted to choice dwarf plants. The Asclepias Gentian, some of the American perennial kinds, and those with herbaceous shoots, generally grow freely in good moist soil in borders. So does the well-known Gentianella (Gentiana acaulis), which, however, being dwarf in habit and large and splendid in bloom, is used as an edging plant. It is well to form carpets of this in parts of the rock garden, planting in deep moist loam. The other type of Gentian, represented most familiarly by Gentiana verna, is by no means so difficult of cultivation as is commonly supposed. Want of moisture in the soil, want of free exposure to sun and air, and weak and imperfectly rooted plants are the main causes of failure. In the cool natural pastures and uplands, where the plant thrives in a wild state, it is rarely subjected to such drought as in a parched, cracked, and baked border. Deep, moist, sandy loam will suit it perfectly; if the

Gentiana acaulis.

surface be strewn with bits of broken stone, it is prevented from cracking and parching, as it often does when bare. Well-rooted plants should be secured to begin with. It is important that the plant be not overshadowed or overrun by tall or straggling border flowers. This is easily guarded against by associating with it plants

Gentiana cruciata.

somewhat resembling it in stature. These various conditions observed, the Vernal Gentian will soon spread into strong tufts and take care of itself from year to year, forming carpets on the rock garden and small beds or edgings on the level ground. The conditions it requires frequently occur in our gardens, particularly in elevated or sea-shore districts, and in these it

Gentiana asclepiadea.

may be grown as edgings to groups of dwarf shrubs, &c. It is quite easily grown in pots or pans of sandy loam plunged to the rim in the open air in a fully exposed spot in summer, and freely watered through the growing season.

Iris nudicaulis.—This has the vigour of the German Iris, which thrives so well on all soils in town and country, and the dwarfness of the old Crimean Iris. It is, however, much sturdier than this, and is second to no hardy plant introduced of late years. It is suited for the front ranks of the herbaceous border, and also well deserves a position among the more vigorous plants in the rock-garden, being so dwarf. It should be in every garden where early summer flowers are valued. I first saw it in the Paris gardens in 1867, and brought home some plants, which have since multiplied, so that the plant is now easily obtained.—W.

NOTES ON HARDY FLOWERS.

Aubrietias.—Some find these difficult to propagate; my practice is to pull off all the straggling side shoots now from the old plants, securing as much stem as possible, and breaking it off close to the main root; then a piece of ground is dug in a cool, shady border, into which is worked plenty of rough sand and leaf-mould; the shoots are then planted in lines, a little sandy soil being placed about the portion put into the ground, and all is trodden down firmly. The cuttings are then occasionally sprinkled and kept shaded from the sun, and thus managed, but few failures occur. One great advantage in getting the cuttings started now is that the plants become strong and dense by the end of the summer, and are well fitted for planting out. The best of the Aubrietias are Campbelli, Eyresi, græca, and the pretty variegated form of deltoidea; this requires careful treatment in the way of striking cuttings, which do best in pans of light sandy soil, kept moist and cool.

Dianthuses.—Among these there is the charming D. alpinus, dwarf in growth, and bearing large deep rose-coloured flowers. I find it does best in pots in a gritty sandy soil, and kept in a cool, shady place. D. barbatus, or the common Sweet William, is now blooming freely, and some of the improved forms are very beautiful. Sweet Williams generally are not sufficiently well cultivated, and the consequence is they fail to bloom so finely as they would do under better attention; I have seen some with flowers of great size and very handsomely marked. D. superbus, the flowers of which are deep pink and handsomely fringed, is a very valuable decorative plant, but sharing to some extent the prejudice which attaches to fringed flowers. It is now blooming with me in pots, and I am looking forward with some interest for the blooming of some seedlings. The showy annual Dianthuses, such as D. Heddewigi in particular, are beautiful both in borders and in a cut state. The latest selection is termed D. diadematus, the flowers of which are more or less handsomely marbled.

Foxgloves.—These look well as a background to mixed borders, associated with Larkspurs, Dahlias, Hollyhocks, and other tall-growing plants. I was looking over a bed of the improved varieties a few days ago, and very beautiful many of them are. Instead of only the ordinary purple and white kinds there can now be found flowers with rose, lilac, pink, and blush exteriors, the blossoms large and of fine form, and the throat or lip very handsomely spotted. It is in this rich, bold spotting that the beauty of the Foxglove so much consists. The small brown spots characteristic of our wild Foxgloves have been converted into large, rich, dark blotches and spottings, and when these markings are in combination with pure white tubes, the effect is strikingly beautiful. Foxgloves are now getting into full bloom, and in the case of extra strong plants there is first the massive centre or main spike, and then a number of side growths come forth later. Those who do not require to save seed should cut out the centre spike as soon as it gets shabby, and the side shoots will be considerably benefited thereby, especially if a good supply of water be given at the roots in dry weather. In the case of the best varieties a side shoot will supply an abundance of seed. If the seed be sown early in spring the plants will become strong for planting out in autumn, and will flower the following June. A good yellow Foxglove would be acceptable; but seedlings from D. grandiflora or D. lutea do not show any material improvement on the parental type.

Gladioli.—Gladioli, whether in masses or grown singly, require attention during hot, dry weather. In the case of a bed of fine seedlings the surface has just been gently stirred, and a mulching of 2 in. of good manure laid over it. The bed is well syringed every evening, and the falling water carries down to the roots much of the invigorating properties of the manure. Some of the shoots are coming up remarkably strong, and they are already being secured to stakes to

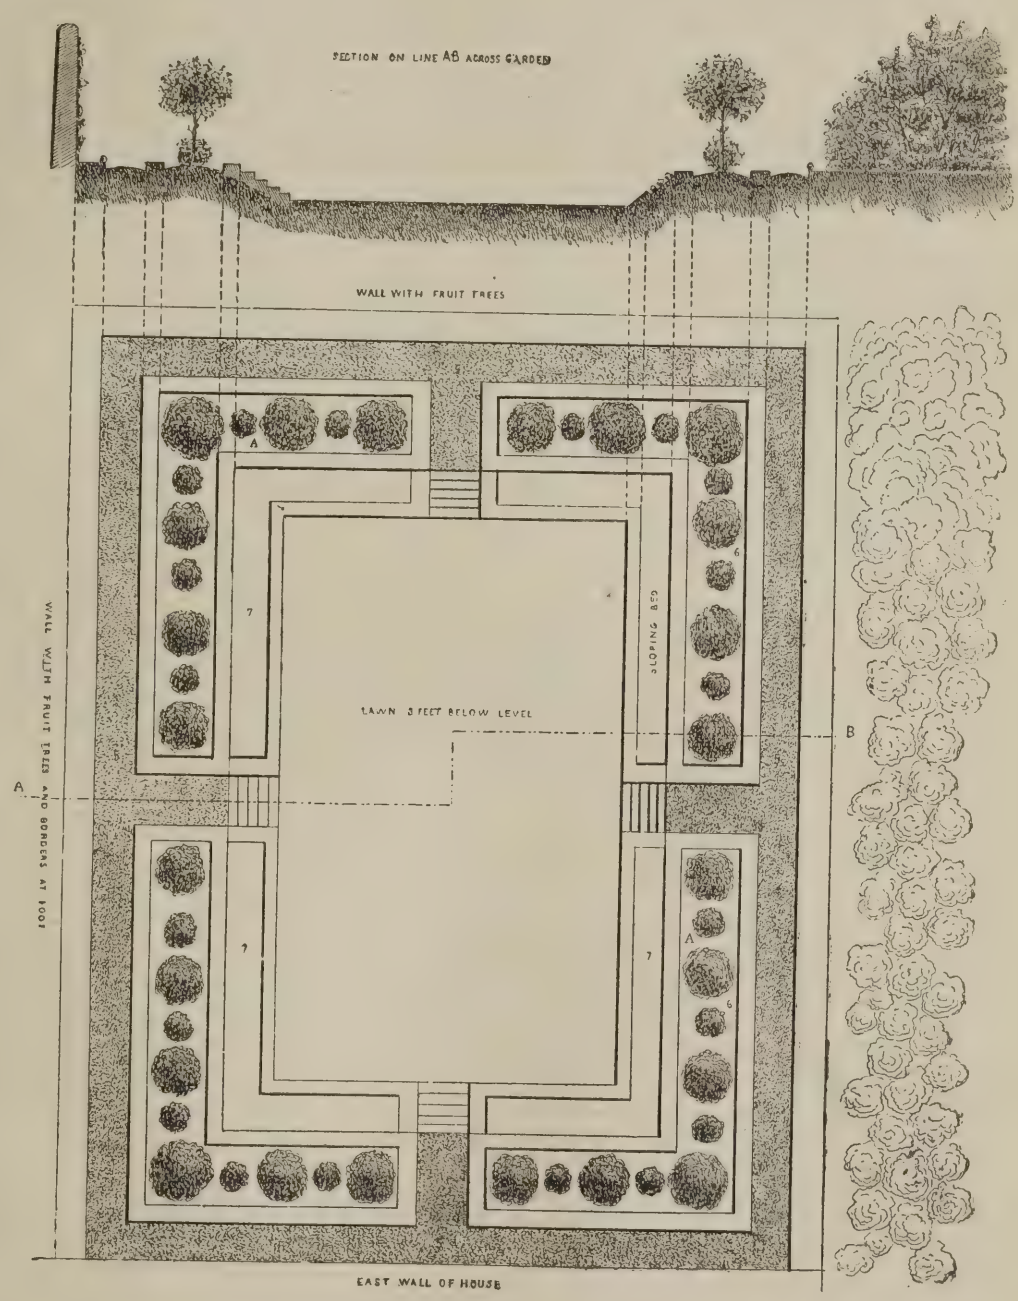
prevent them from being broken off by the wind. The following early-flowering species richly deserve a place in the mixed border, viz.—G. communis, the flowers of which vary somewhat, being occasionally white, blush, or pinkish-rose; G. cardinalis, red; and G. ramosus, rose, of which there are some very beautifully-coloured varieties.

Lathyrus.—Under this head we have the Everlasting Peas, among which L. grandiflorus is used largely for training on cottage walls, and it is already in full bloom in sheltered spots. It makes an excellent summer fence if planted against iron railings or anything of the kind that will afford it support; the flowers, which are of large size and handsome, are produced with great freedom; once planted, it will continue to grow up in spring and bloom in early summer for years. L. latifolius, the common Everlasting Pea, is so well known as scarcely to need mention, but it is, nevertheless, invaluable in gardens. L. Drummondi, the scarlet or carmine Sweet Pea, is much scarcer; it is extremely pretty, but requires to be somewhat in the shade, as the sun scorches its gay flowers and spoils their effect; like the others, it is propagated by seed and root division.

Mimuluses. — Mimuluses in pots should now be in a cool north house, as hot weather, when the plants are fully exposed to the sun, is very trying to them. By keeping them cool and shaded their beauty can be prolonged for a considerable time. Some seed sown now would yield plants that would bloom in August and September. Harrison's Musk deserves a word of praise. The habit of growth and character of the common Musk are maintained, but the flowers are spotted, large, and handsome. Musk is greatly helped by being potted from 2 in. to 3 in. deeper than usual, and then gradually filling up the pots with rich soil as the plants make growth; in this way fine examples of Musk can be had. I am treating the large kind in a similar way, and with good results.—D.

To Propagate Hardy Herbaceous Plants. — This may be readily accomplished either by division of the roots in autumn or spring; by cuttings put in on a shady border in summer; or, in some instances, by seeds sown in autumn or spring. Cuttings of the young shoots will root readily about June and July in a cool shady border. It is best to prepare a small bed by adding sand, road-scrapings, and leaf-mould, as the cuttings can be put in when convenient. Pansies, Pinks, Carnations, Phloxes, Penstemons, and all hardy plants can be propagated in such a bed. A few pliable sticks can be hooped over the cuttings, and a mat or some protecting covering placed over on bright, sunny days. The cuttings may be from 2 in. to 4 in. long, according to what kinds they consist of, and should be cut across just under a joint with a sharp knife; if the knife be not sharp, the tissues, instead of being smoothly cut, will be bruised, and so much damaged as to stop all circulation, and the cutting will probably damp off and decay instead of forming roots. Unless the leaves are large and flaccid, it is not advisable to remove more than the bottom pair, so as to give room to insert the cutting, for the leaves have a most important function to perform, and the more leaves a cutting carries, always provided they can be preserved from flagging, the sooner roots will be formed. Of course if a hand-light or a close frame be at hand to keep a close atmosphere round the cuttings, their rooting will be more expeditiously and certainly accomplished.

Dwarf Plants for Rhododendron Beds.—Numbers of beautiful dwarf plants may be grown with advantage in Rhododendron beds where peaty soil exists, as, for example, the Starflower (Trientalis), the white wood Lily (Trillium grandiflorum), variegated Partridge Berry (Mitchella repens), the Blood-root (Sanguinaria canadensis), the Podophyllum, the wood and the common Forget-me-nots, Rhexia virginica, Spigelia marylandica, Cypripedium spectabile and pubescens, Gaultheria procumbens, Linnæa borealis, Epigæa repens and Epimediums in variety, Acæna microphylla, Asperula odorata, Campanula hederacea, Cornus canadensis, Dryas octopetala, Erpetion reniforme, Hepatica angulosa and the varieties of the common species, Ionopsidium acaule, various Mimuluses, Nertera depressa, Nierembergia rivularis, Phlox reptans, Selaginella denticulata and helvetica, Smilacina bifolia, different kinds of Violas, and double Primroses in variety. For growing near the centres of large beds such plants as the Lilies, Gladioli, and Sparaxis pulcherrima are admirably suited.



Plan for a Spring Garden.

PLAN FOR A SPRING GARDEN.

THE accompanying plan is offered to the readers of GARDENING as a suggestion for bringing the whole beauty of the spring together in the flower garden as a prominent feature. When a suburban house is built in a rectangular plot of ground, set well back from the road, so as to have a good entrance court, there will be a space at least at one side of the house which is a little difficult to treat ornamentally. This space I suppose to be used as suggested. There are two fruit walls with continuous borders at the foot of them, in which wall fruit trees are grown,

and a shrubbery and plantation, screening the spring garden from the other pleasure grounds in summer when its beauty is over for the season. No. 5 is a continuous walk; No. 6, beds filled with standard Apple, Pear, Plum, and Cherry trees, with Currant and Gooseberry bushes or flowering shrubs between them; these beds are surrounded with Grass verges. No. 7 are beds on a slope with Grass verges. In the middle is a lawn sunk 3 ft. below the general level, and reached by flights of steps. The shrubbery should consist mainly of deciduous flowering trees and shrubs which flower early, such as Laburnum, Wistaria, Thorns, Almond, Double-flowering Cherry, Horse Chestnut, Daphnes, &c., &c., with an undergrowth of Wood Anemones, Scillas, and Hoteia japonica, and front lines on the north side of Christmas Roses, Winter Aconites, Hepaticas, Lily of the Valley, Columbines, &c. The borders 6 6 will afford sunny and partially-shaded positions for a selection of spring-flowering bulbs and annuals, but only those should be chosen which can either be lifted or will have entirely finished their growth by the time the fruit has to be gathered. The beds 7 7 will afford situations for a selection of the very choicest spring flowers—Auriculas, Polyanthuses, Primroses, hardy Primulas, Narcissi, Pansies, Anemones, Ranunculus, and Iris japonica. By the second week in June the gates of the spring garden should, metaphorically speaking, close for the season. J. D.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

June 21.—Potting Anne Boleyn Pinks; putting Cockscombs into their flowering pots; planting out some old Pink plants that have been forced; also Stocks, Asters, Perillas, Veitch's Autumn Giant Cauliflower, Snow's Broccoli, Savoys, and Scotch Kale; putting Lycopods in boxes for the conservatory; leaving abundance of air on Peach house in which the fruit is ripening; layering Strawberry runners and earthing up French Beans; sowing Snowball, Red Globe, and American Strap-leaf Turnips; planting out Capsicums in open spaces against south walls; potting on Balsams and Petunias; giving early exhibition Celery a little earthing; putting sticks to all flowering plants that require it.

June 22.—Sowing two rows each of the following sorts of Peas: Laxton's Omega, Ne Plus Ultra, and British Queen; planting out Borecole, Brussels Sprouts, and late Broccoli; putting in cuttings of choice sorts of Pelargoniums; giving all newly-planted bedding material a good watering, and pegging down any plants that require that attention; looking over Globe Artichokes, and cutting off all stems and heads not required for use; looking over Cucumbers and Melons and stopping the shoots; watering all newly-laid Strawberry runners; potting off young seedling Carnations; shifting large Coleus into larger pots; sowing Maclean's Wonderful Pea, Round Spinach, and Stone Snowball and the American Red Turnip; also French Beans and Lettuce; digging land in which to plant another crop of French Beans; nailing Apricot, Plum, and Peach trees out-of-doors.

June 23.—Planting out in the open air newly-struck Pink and Carnation cuttings; keeping floors of Vineries where fruit is swelling frequently watered; digging all vacant ground and hoeing between growing crops; tying in all leading shoots of espalier Pear and Apple trees; sowing Imperial and Heartwell Early Marrow Cabbage; also red and white Turnip Radishes; planting out Lettuces and Endive; cutting back Laurels encroaching on walks; pegging down and stopping Vegetable Marrows; thinning Turnips; putting strings round Peas that are forcing their way through the sticks.

June 24.—Sowing Giant White Cos, the Favourite, and All the Year Round Lettuces; planting out Celery and Cardoons; picking flowers off and tying out Fuchsias for exhibition; finish clipping all Box edgings; looking over all cordon-trained Apple trees, tying down leaders, and loosening any that require it; shifting Achimenes into their flowering pots; also dwarf Chrysanthemums; digging ground lately occupied by Lettuce for French Beans, adding plenty of well-rooted manure; syringing Ferns for thrips and green fly.

June 25.—Sowing Broad-leaved and Green Curled Endive; also Canadian Wonder Beans, Spinach, Mustard and Cress; stopping and nailing in Tomatoes; thinning out Parsley and Spinach; watering all newly-planted fruit trees; putting loose ties round all young Raspberry canes to protect them from the wind; pinching back the breast wood of Cherry, Pear, and Plum trees and nailing in the leading shoots; sowing some dwarf and Negro Long-pod French Beans; also various kinds of Endive; planting Broccoli amongst Potatoes; plunging Roses that do not require re-potting; thinning Salsafy, Scorzonera, and Turnips; potting old forced bulbs that have been well dried in hampers and storing them away; leaving a little air on Vinery all night where Grapes are changing colour.

June 26.—Potting Stocks, Heliotropes, and Carnations; thinning out Lettuces and Endive; also late-sown Carrots; nailing and tying in all Roses, creepers, and Ivy on walls and trellis work; placing sticks round Asparagus beds to protect the young growths from wind; watering all newly-planted Celery; putting large standard Heliotropes into their flowering pots; shifting scented Verbenas into 8-in. pots to grow on for cutting purposes; potting Arum Lilies, Gesneras, and Justicias; sowing Nonpareil Peas and main crop of Endive; pegging down Verbenas and Petunias in flower garden.

Glasshouses.

Plants under glass are now growing vigorously, therefore cold draughts must be avoided as much as possible; there must, however, be plenty of ventilation; abundance of water must also be given, and shade of some kind provided as a protection to plants in bloom, the beauty of which soon becomes impaired if exposed to sunshine. Give weak manure water to gross-feeding plants, and from specimens planted out in borders remove all superfluous shoots and suckers. Fuchsias trained to rafters require thinning, and Clematises tying to trellises. Do not allow deciduous climbers to intertwine with evergreen ones, as they apt to spoil the latter. Keep up a succession of Hydrangeas, zonal, show, and sweet-scented Pelargoniums, Fuchsias, Coleuses, Lobelias, Salvias, Cockscombs, Balsams, Schizanthuses, and similar plants, and transfer to frames or the greenhouse such plants as have done flowering. Heaths and some early-flowering hard-wooded plants may now be set out-of-doors on a bed of ashes. Old plants of Agapanthus umbellatus should have plenty of water and a sunny position. Cut in hard-wooded Veronicas that have done blooming, so as to encourage fresh growth. Pot off seedlings of Primula japonica and keep them out-of-doors, where they form stronger plants than if nursed under glass. Plants of Kalosanthes should now have some assistance in the way of stimulants, as should also Liliums that have formed their flower-buds, and some other soft-wooded plants. Erythrinas in pots should be grown in a cool and light house near the glass; they require plenty of water, and their main branches should have supports of some kind to keep them in proper position. Bouvardias that were cut back after flowering should now be making good wood; they must, therefore, be kept moist and warm for some time yet. Persian Cyclamens should be kept in cool and shady frames, or against north walls; they should receive a little water during the summer months: C. Coum and similar kinds should be kept moderately dry, but not too much so. Azaleas that have done blooming, and which have had their seed-pods picked off, should be re-potted, if necessary, and put into a warm pit, where heat, moisture, and shade can be given them. Camellias also make good growth under similar conditions, as do also Oranges of various kinds. Pinching in should be practised freely until the plants have attained the form it is desired they should assume.

Chrysanthemums.—The time of putting these plants into the pots they will bloom in will, as a matter of course, be regulated by the time at which they were struck. Such as are grown from cuttings put in about the close of the year, and which will produce a greater profusion of fully-developed flowers than the later struck ones, will, as already advised, be ere this in their blooming pots, and all the later propagated ones should at once have their last shift; for if kept confined in little pots too long the certain consequence is the loss of the lower leaves and a hardened condition of the shoots, both of which it is not possible afterwards to set to rights. Leaf-mould as a mixture with the soil is sometimes recommended for Chrysanthsmums, but when this is employed the plants have a greater disposition to make shoot growth than to flower freely. Good turfy loam, with a moderate addition of sifted rotten manure and sufficient sand will grow them well, potting firmly. As soon as they have got fairly hold of the soil stop the shoots as far as necessary, but not more, as this pinching is frequently carried much too far and resorted to too late, in which case it interferes with the blooming.

Auriculas.—The earliest potted plants are now making strong healthy growth, and afford a striking contrast to those not potted; the latter have also made growth, but the difference between the two is easily recognised, and the leaves are not nearly so richly coloured. A correspondent asks, "What am I to do with plants that have finished flowering?" The answer is, Pot them at once, and place them in a frame behind a north wall, or some similar position. Keep the frame close for a few days, but not quite close; tilt the lights at the back an inch or two. In potting remove nearly all the soil and examine the tap root; this is often in a state of decay, but whether it is so or not, it ought to be shortened. Let the soil be light and moderately rich; it should be composed of, say, four parts turfy loam, one of leaf-mould, one of rotten manure, and some sharp sand. The largest plants may be potted in 5-in. pots, and the smaller samples in 3-in. ones. Over-potting is a great evil.

Flower Garden.

As soon as fine weather sets in stir the surface soil of the beds, for the rains harden it to such an extent that if not moved it soon cracks, and growth is checked. A small hoe or hand fork can be used for this purpose, except in the case of carpet beds, which, being planted thickly, a hoe cannot be used; recourse must therefore be had to a sharp-pointed stick, with which a handy boy will stir up many beds in the course of a day. With an eye to effectiveness, let all ground work, edgings, and divisional lines be kept true to design by frequent and regular pinchings or peggings; if time thus to keep them in order cannot be afforded, no attempt at geometrical arrangements should ever be made; on the contrary, preference should be given to masses of colour arranged in lines or circles, broken at regular intervals by means of "dot" plants, in order to obviate the monotony of flat surfaces. All kinds of bedding plants will be the better for having their flower stems picked off till growth is established; at all events none should ever be allowed to seed, which Violas and Pansies are already doing, and if not picked over they will soon give up flowering. Calceolarias never fail to flower throughout the season if their flower stems be pinched off once after planting, and the same may be said of Lobelias, which we clip over with sheep shears. Tall bedding and sub-tropical plants will require support, which it is best to provide at once, ere injury accrues through storms of wind or rain. Small twiggy branches make excellent supports for all plants that do not exceed 2 ft. in height, such as Petunias, Perilla, and Calceolaria amplexicaulis; but all large-growing sub-tropical plants must have separate stakes proportionate to their height, and the same remark applies to Dahlias and Hollyhocks, the growth of which is more robust than usual. Standard Roses may also require renewal in the way of stakes lest their heads get overweighted and break off; keep them free from suckers, and in showery weather sprinkle the beds with soot or guano, as where neatness has to be studied surface mulchings of rotten manure—the best stimulant—are not always practicable. Keep dead and decaying flowers picked off, and as soon as any have done flowering, more particularly those of a straggling habit, shorten back the shoots in order to induce a second bloom. Complete the thinning and planting out of annuals; this has been a favourable season for such work, and if properly done a fine autumnal display may be expected—that is, if the plants be protected from slugs, which unfortunately are very numerous. As soon as planting is finished, there should be a general clearing up of walks, clipping and trimming of edgings, or any other operation that may conduce to neatness.

Peg down Petunias, Verbenas, old and leggy Pelargoniums, Tropæolums, &c., so as to render them as effective as possible. Bracken or small Beech pegs are excellent for this purpose. Have a stock of Lobelias in reserve to take the place of inferior kinds, which often appear where seedlings are used. Edgings of Cerastium should be gone over weekly, and all flowers cut off with a pair of shears; flowering shoots should likewise be picked off all plants of the variegated Jacob's Ladder, Golden Feverfew, and other plants grown only for the beauty of their leaves. A good supply of reserve plants for future stock should now be secured—for instance, Centaureas kept in pots during the summer time are better for propagating from than plants lifted out of the soil. See that the more common kinds of Carnations in beds and borders are kept clean; they are sometimes attacked by a maggot which eats into the centre bud. This, when perceived, must be destroyed, even if the bud has to be sacrificed.

Dahlias and Hollyhocks.—As Dahlias advance in growth see that they are kept regularily tied up. They should have three or four sticks to each plant, so as to keep them open and allow the sun and air to get to the centres. The

practice of tying these plants up to a single stick is bad and unsightly; it causes them to run up tall and affords little security against strong winds. To induce the plants to throw out strong side shoots pinch out the points of the leading growths. See that they are quite free from aphides, and if any are detected, syringe with Tobacco water. Hollyhocks must be well secured to stout sticks as they increase in size, for if they get blown over it spoils them. They do not require the sticks so long as those sometimes used, unless grown in very exposed places, in which they should not be planted. If the sticks are 4 ft. out of the ground, after being firmly driven down, they are high enough. Do not tie them so tightly as not to allow sufficient room for the stems to thicken. On the other hand, they must not be left so loose as to chafe with the wind against the supports.

Herbaceous Plants.—These being now in great beauty, a little extra care should be bestowed on them. Lift such Hyacinths, Tulips, and Crocuses as interfere with them, and spread them out to dry without removing any of the leaves. Cut over the decaying stems of Snake's-heads (Fritillarias) and similar early-flowering plants. Gather seeds of Squills as soon as they are ripe, and sow them at once. To plants that require support apply strong stakes, but Campanulas, Larkspurs, Pentstemons, Antirrhinums, Pyrethrums, and some others of a similar character look best when unsupported in that way. Transplant hardy Primulas kept in pots on to a shady border, where they should be kept clean and secure from slugs; P. japonica always grows better when planted out-of-doors than when grown in pots. A mulching of rotten manure, spent hops, Cocoa-nut fibre, or leaf-soil should be spread over the ground, and if its appearance on the surface is objectionable cover it with soil. Phloxes like plenty of nourishment, consequently a little manure water should now and then be given them. Everlasting Peas wintered in pots may now be planted out. Viola cornuta and other bedding Pansies should be kept well furnished with young shoots by occasionally cutting out the old ones, and the beauty of both English and fancy sorts will be greatly prolonged if they are grown in a moist and partially-shaded situation. Train Clematises in such a way as they will look best. Such herbaceous plants as have been wintered in frames may now be planted out, but in the case of plants intended still to be kept in pots, a shady position on a bed of ashes is best for them; and upon no condition should they become at any time perfectly dry. Remove decaying flowers, except in cases in which seeds are to be sown. Double Rockets which have bloomed should have their shoots layered, an operation which will soon induce the production of shoots in abundance, and these, when they have attained a length of 2 in. or 3 in., may be taken off and made into cuttings. Pyrethrums for late blooming, if cut down and allowed to grow afresh, will come into bloom during the later summer months. Hardy perennials generally which bear division may still be multiplied in that way, and where that is not applicable, cuttings should be inserted as soon as possible, in order to ensure their becoming well established before winter. Hardy annuals for late blooming should be sown in shady spots, to be transplanted hereafter to the positions in which they are to flower. Seeds of Brompton, Emperor, and Queen Stocks should also now be sown for flowering next spring. Continue to prick off perennials as soon as they are ready for removal. Plants in pots will require plenty of water at this season, and specimens of such plants as Phloxes, Pæonies, Pyrethrums, &c., will need attention in the way of staking and removing dead blooms. If not already done, lose no time in plunging the stock of plants in store pots in wood-ashes or sand.

Vegetables.

The cutting of Asparagus must now be stopped, and the beds will be much benefited by a good soaking of manure water; this, being a marine plant, enjoys salt, which, if it be added to the liquid at the rate of 2 oz. to a gallon, will materially assist Asparagus beds, especially such as have been long in bearing. Keep the beds quite free from weeds, which it is necessary in this case to remove by hand, as the use of the hoe would interfere with the plants. Beds that have been much cut should at the present time be encouraged by every means to make good growth, for on this depends their ability to keep up in years to come their producing powers, both as regards quantity and quality, in a satisfactory state. Asparagus often gets worn out much sooner than it otherwise would through suffering neglect after cutting has ceased. Advancing crops of Carrots should be again looked over to see that they are not left too thick, especially the main sowing. Turnips also will require attention in this respect; there are few crops suffer so much as this if allowed to stand too close together, as when in this state they run to leaf, forming bulbs that are not only small, but very poor in quality.

Thin the main crop of Beetroot before the plants get so large as to interfere with the growth. Some Colewort seed should now be sown; these will be useful for planting thickly late in the season after other crops are cleared off. In respect to this vegetable it is necessary that amateurs should make sure that they get the seed true, and not some small kind of Cabbage which is sometimes substituted for it, as the Colewort will turn in its leaves and make useful heads when planted later than any variety of Cabbage; it also may be planted under fruit trees when these are not grown too close. Of course they will not produce anything like the crop they will in an open situation; nevertheless, what they do yield is so much gain, and they help to keep down weeds.

Where dwarf French Beans are held in particular estimation a few more may at once be sown; these should occupy a south border, under the shelter of a wall, where, by a slight additional protection from September frosts, they will frequently go on bearing longer than those grown on more open situations. Autumn-planted Cabbages that have been cut and the stools left to produce a crop of Sprouts should, where the sand is at all poor or of a light nature, have a good soaking with manure water, by which, in addition to thinning out the shoots to some two or three to each stool, they will make small useful heads, that will come in through the autumn. Keep the hoe going on all favourable occasions amongst advancing crops of every kind.

Hardy Fruit.

Any trees that are fruiting freely, and which, on account of others being thin of fruit, must carry a heavy crop, should have assistance either in the way of manure water or a rich surface mulching, or an occasional sprinkling of guano. The application of such stimulants are doubly valuable when applied early in the season. As soon as the fruit has formed and is starting to swell is when they are most effective; after that period they are comparatively valueless—at all events as far as the present season's fruit is concerned. Pears and Plums on walls now need to have all the breastwood cut back to within two, or at most three, joints of the old wood; but previously select all new growths that are to be laid in as permanent branches, and tie, nail, or fasten them back temporarily with small sticks; then remove all the strongest-growing shoots from every part of the tree, and complete the operation at an interval of a week, thus avoiding the check that must necessarily ensue were all cut off at once. Finish thinning out any clusters of fruit requiring it, and let all wall trees be washed with clear water to dislodge the fallen blossoms and cobwebs. No time should be lost in keeping Strawberries off the soil by a thin layer of straw; this we never require to do, our practice being to give a thick mulching of fresh stable litter early in May, and this by the time the fruit needs protection is washed clean by the rains. All varieties have grown so vigorously that small twigs to support the clusters of fruit will be almost a necessity, and certainly of immense service against the ravages of slugs, which are numerous. Disbud, stop, and train in new growth on Vines in the open air where such is required, as in the case of indoor Vines; young canes produce the finest fruit, and provision should be made for the renewal of old ones, by occasionally training in new shoots to take their place at the winter pruning. The season will also be a short one for Figs, and the fruit will require all the aid that can be afforded in order to enable it to mature, such as exposure to full light and sunshine, by tying aside the leaves, and stopping all growths at the third or fourth joint, except those that are required to cover the wall. Such constant stopping not only represses growth and induces fruitfulness, but aids materially the swelling of the fruit. Loosen or untie altogether as may be requisite the ligatures of grafts; as a rule, it will be safe to dispense with ties altogether, and the only attention now requisite will be to keep the stock free from shoots and suckers; these latter should be persistently removed from all fruit trees.

House and Window Gardening.

Graceful Basket Plants.—Nierembergias are highly esteemed in London for furnishing small vases or window boxes, and deservedly so, for few plants are more graceful or better adapted for the purpose. N. gracilis, with small blue and white flowers and dwarf habit, and N. frutescens, possessing an upright habit, and bearing large white flowers with mauve-coloured eyes, are the chief kinds used, and it is satisfactory to find that by crossing these two kinds intermediate varieties have been raised which possess a better habit of growth than that of the parents, and by again crossing these with N. gracilis the result is good habit, large flowers, and fine blue, white, and mauve colours.

The Golden-edged Cocksfoot Grass.—This Grass is useful for many purposes, as from its perfect hardiness it may be grown

Golden-edged Cocksfoot Grass (Dactylis glomerata aurea).

as an edging in rows, or as isolated plants in open borders; and it is equally adapted for growing in suspended pots for the decoration of the greenhouse or conservatory, or in ordinary pots for edging or fringing plant stages. There are two variegated forms of this Grass—one with golden-striped leaves, the other with the variegation much whiter, and the stripes considerably broader.

Tuberous Begonias as Basket Plants. We find these Begonias to answer admirably when grown in hanging baskets; in fact, with us they both grow and bloom much more freely than when grown in pots. This is doubtless caused by the roots not being so much confined as in pots. The way in which we use them is as centre plants in the basket, employing some other plant to cover the outer surface. One basket planted in that way with a seedling variety very much like Vesuvius has seventy flowers now open, and the outer surface is covered with a dense mass of Harrison's Musk, which is also in full bloom. The pale yellow flowers of the Musk, and the scarlet blossoms of the Begonia produce a striking effect. We find it necessary to use baskets of a considerable size; ours are of a semi-circular shape, made of thin wire, and are about 11 in. in diameter at the top, and 10 in. in depth at the centre. The compost which we use is a mixture of equal parts loam, leaf soil, and fibrous peat.—H. J.

The Japan Primrose (Primula japonica).—For pot plants intended for windows, strong seedling plants, potted in September in a compost of turfy loam mixed with a liberal proportion of leaf-mould and rotten manure, are suitable. I use long narrow pots, 5 in. diameter at the top and 11 in. deep, such as are used for Hyacinths. It is a plant which requires a deep

pot, in order that its long thick, fleshy roots may grow downwards. It requires a great quantity of water, and should be supported with frequent doses of liquid manure. If grown out of doors, the flower-stems should be supported by small flower sticks, in order to protect them from injury from wind and rains.—H.

FRUIT.

SUMMER PRUNING FRUIT TREES.

IN the case of espaliers, or indeed any other trained or restricted fruit trees, summer pruning or pinching assumes very great importance, from the power and control it gives the cultivator over the trees. Should the bottom branches of the trees show any signs of weakness, leave them unpinched for a season or two, but pinch more closely and assiduously the stronger-growing parts, to divert the flow of sap into the weaker parts. By pinching the growing shoots of trees the flow of sap may be turned in any direction, in the same way that the flow of water can be regulated by a tap attached to a water-pipe. Pinching a shoot stops the flow, whilst leaving it unpinched encourages the flow in that direction. The question of summer pinching is deserving of very close study, not only in its application to fruit trees generally, but the best mode of treating each particular tree should be separately considered. There is too much variation in the strength of fruit trees to permit all to be treated exactly alike without in some cases causing derangement in the health of the trees; for whilst the strong grower must be repressed, it may be necessary to leave the weakly one untouched, and even by further means to encourage growth. Pinching, quite as much as root-pruning, enables the growing power to be repressed, and in a more natural and less hurtful way, because the check can be given gradually and at the right time. In most cases summer pruning is delayed too long, often till the young shoots are 1 ft. or more long and are getting firm at the base, and then perhaps they are cut back to three or four buds. But during the time of this rapid extension of wood the roots have felt the stimulating effect of so much foliage; and as in many cases cultivation is carried on almost up to the trunks of the trees, the roots have no chance but to strike downwards; and as this occurs year after year, the system of the tree gets out of order and refuses to bear fruit or blossoms, and of course when that condition is arrived at the only remedy is to lift, root-prune, and re-plant. But if the growth had been attended to earlier, a regular steady root action would have been carried on in proportion to the growth, for there is always a reciprocity of action between roots and branches, and when the latter are encouraged or allowed to extend themselves, the roots, to meet the heavy demand made upon them, must descend into the moist subsoil; and when that takes place, nothing but watery unripe wood will be produced till the tree is lifted out of the cold stratum, and its roots brought back nearer to the surface. In the meantime there is a season or two lost, and there is a possibility of the roots being trimmed in too much, and then the tree will require a year or two to recover its proper healthy and vigorous tone. In dealing with a well-balanced tree, the most reasonable way of proceeding would be to commence pinching when the longest shoots had grown 7 in. or 8 in., and shorten them back to five or six buds, going over them at intervals of three or four days until all were pinched or shortened back, making the time extend over three or four weeks. In this way no undue pressure would be placed on the roots, and the tree would be maintained in a healthy and vigorous state through both roots and branches; the sap that ran to waste in watery spray would be diverted into forming fruit-buds, and an early fruit-bearing habit formed that would tend still further to check any undue development of useless wood. When summer pinching is intelligently and well carried out, there is only in extreme cases any necessity to resort to root-pruning.

Figs Failing to Ripen.—As a rule, Figs do not succeed well in the north-western neighbourhood of London, as the soil is only clay, with perhaps 9 in. of good soil on the top. It may, therefore, be interesting to many of your readers if I inform them how I treated several of these trees successfully. I first took out the clay soil to a depth of 5 ft., and then put in 2 ft. of mortar rubbish—first, however, leading a drain to the bottom of the hole to carry off superfluous water. The hole was then filled with some loam, and a little mortar rubbish intermingled with it, in the proportion of about one barrowful of rubbish to a cubic yard of loam; and, after the soil had settled, the plants were put in. By careful training and summer pruning, the trees, which were old ones, bore very well the second year, and have since ripened good crops. I should add, perhaps, that the trees are in a close warm corner, facing due south, and that mats are thrown over them during winter.—W. J.

GLASSHOUSES AND FRAMES.

MANAGEMENT OF GESNERAS.

GESNERAS being for the most part tuberous-rooted plants, by judicious management can be had in bloom the whole year round. They are not difficult to cultivate; anyone having a Melon or Cucumber pit, or a stove house, which is better, and a Vinery or a warm greenhouse for summer quarters, can grow them well. They

Gesneria refulgens.

like partial shade and plenty of moisture when growing, both in the atmosphere and at the roots. A suitable soil may be made up of one-half turfy loam, the other half being peat, leaf-mould, and well-decomposed manure in equal parts; there should also be a liberal supply of silver and sharp river sand, and a good drainage of potsherds or pieces of charcoal. Gesneras should be grown for successional blooming, and as this can be done with a small collection, there should be a series of pottings of the roots. One tuber can be grown in a 5-in. pot, or three or four in an 8-in. pot. Some growers prefer single specimens, which speedily grow into good plants if properly managed, while others prefer large examples, when three or four tubers must be used. The tubers should be started into growth at intervals of from five to six weeks, beginning, say, with the middle of March, and continuing on to early in July, if space can be found for them. The soil should be filled up in the pots to within 1½ in. of the surface, so as to leave room for some top-dressing, and it should be gently pressed about the tubers. The pots should then be plunged in a gentle hotbed, if possible (but they will do without), in order to start the tubers into growth, and here they can remain till the shoots are about 4 in. in length, when they may be removed to a warm, dry, and light part of the stove near the glass. There must be no stint of water when required—in fact, Gesneras like plenty of moisture about the roots, so long as there is a free drainage, but they dislike the lodgment of water on their leaves, and therefore they should not be syringed overhead, as the leaves become much disfigured through water lodging on them. Each stalk should be tied to a stake, as the plants make a free growth, and require to be tied out so that the finely-marked leaves may be set off to the best advantage. After all, a single specimen in a pot is better than several of irregular growth; besides, a large pot containing small plants frequently has a confused appearance. There must be no neglect after the plants have done flowering. Indeed, to keep Gesneras in robust health, they must be well attended to after flowering, for then the bulbs for the following season have to be matured. In order to effect this, they must be carefully tended, giving them occasional waterings with weak liquid manure; but as the foliage begins to decay, less water will be required, and when the growth is finished, water must be entirely withheld. After this, though requiring to be kept dry, they must not be baked, but should be stored away in their pots in a cold dry place until again required. It is a common practice to shake the soil away from them when dry, and to store the bulbs in dry sand; but the best system is to leave them in their pots, and just start them into growth in the old soil before repotting, for by this treatment the bulbs are not so liable to injury, and the plants consequently flower much stronger. The following varieties are all well worth cultivating, viz.:—Barlowi, the leaves of which are bright green, covered with crimson hairs; the flowers are a delicate shade of salmon, slightly spotted on the throat. Chromatella, a kind with dark velvety leaves and elegant erect spikes of drooping rich yellow flowers. Cinnabarina, a variety with green leaves, and brightened with flame-coloured hairs; the flowers bright and cinnabarred, with a pale throat. Doncklaari, a kind with large darkly-tinted leaves and bright vermilion flowers. Exoniensis, a sort with large rich, dark velvety leaves, covered with minute red hairs; the flowers deep orange-scarlet, with yellow throat. Lindleyana, a sort with rich deep velvety green and red leaves; flowers rosy-pink and yellow, freckled with red. Nigrescens, a variety with large dark velvety leaves; dark red flowers, the throat light orange spotted. Zebrina splendidissima, a kind with leaves handsomely marbled with dark bright orange-scarlet flowers. And the one depicted in our engraving, G. refulgens—a handsome kind, both in foliage and flowers.

A FEW ORCHIDS FOR GENERAL CULTURE.

EVERYONE has not facilities for growing Orchids as a collection, and some are deterred from attempting their culture by the idea that they are very difficult to grow. To a certain extent this is true. Most species require special treatment and a good deal more attention than can be afforded in gardens where the labour is limited; but there are a few Orchids, nevertheless, about the culture of which there is nothing very difficult, and which might be advantageously included in any ordinary collection of warm greenhouse plants. Some of these are old and some new, but we will only mention a few that are good growers, free flowerers, and worth cultivating. The first on the list is the old Phajus grandifolius, otherwise known as Bletia Tankervilliæ, and which is a free-growing and vigorous subject, and very ornamental when it throws its magnificent spikes of flower in the spring. It succeeds well in the ordinary stove, and needs but little attention. When the plants need re-potting, the operation should be performed after they have done flowering, and just when they begin to grow. It delights in good strong turfy loam and peat, or leaf-mould, together with sand and plenty of lumpy charcoal and good drainage; in other respects it may be treated like any ordinary stove plant—neither kept too wet nor too dry either in summer or winter; and during the growing season it should have occasional waterings of liquid manure.

Calanthe vestita.—This, though belonging to a different class, is not unlike the first named in miniature, and requires similar treatment. It is a very pretty Orchid, and popular even among Orchid growers. Healthy bulbs, potted two or three together in 6-in. and 7-in.

pots, make nice little specimens. Light turfy loam and peat, with charcoal, form a good compost for it. The bulbs should not be buried in potting, but placed pretty firmly in the soil, and room left for watering. The finest lot of plants of this kind that we have seen were firmly potted in what appeared to be almost pure loam, pressed as firmly about the roots as we would a Strawberry plant. In summer the plants require moderate shade from strong sunshine; and in winter water should be sparingly given, but not entirely withheld.

Cœlogyne cristata.—This is one of the best Orchids for general culture; in fact, it should be grown in batches like the Chinese Primrose or the Cyclamen—and no doubt would be, if it was as easily procured. It grows freely in the stove or intermediate house, and produces its lovely white flowers in great profusion. It may be grown in a basket or pot, or on a block; but the pot is most convenient. Good drainage, fibry peat, Sphagnum, and lump charcoal are essentials; and these should be raised in a firm mound above the rim of the pot, and the plant pegged down upon it. Small plants will make good specimens in a short time, being easily divided, and small plants may be soon propagated when it is desirable to increase the stock.

Dendrobium nobile and its Varieties.—These still rank amongst our finest Orchids, whether regarded for the beauty of their flowers or the profusion in which they are produced. They are very easy to cultivate, and succeed best in fibry peat and loam, Sphagnum, and charcoal, packed pretty firmly together about the roots, and raised in a mound above the rim of the pot in the usual way. Plenty of drainage is necessary. Spring is the time to re-pot, after the plants are out of flower. As a rule, the strongest shoots spring from the base of the old stems; but sometimes they break away from the tops also and elsewhere. The best plan in any case is to peg all growths down to the soil, and encourage them to root into it. An ordinary stove treatment and plenty of water during the summer will easily produce a fine growth by October, when water should be almost withheld; and, unless the plants are wanted in flower early they may be transferred to a cooler house during the season of rest, but not starved or exposed to cold and damp. A friend of ours, who grows large specimens for the room vases, transfers them to his cool Vineries in autumn. In potting, as we should have mentioned, care must be taken to avoid burying the base of the stems; leave all but the roots clear and above the surface of the soil.

Dendrobium Farmeri and densiflorum are two fine species that succeed in the stove or intermediate house, and which, according to our experience, continue to grow and flower under very adverse circumstances. We have known plants that had remained in the same pots for years, and been long subjected to a low temperature during the winter and spring, that hardly ever fail to flower annually. They, however, repay genuine culture, and require the same treatment as D. nobile, except that they are better left in their summer quarters during the winter. None of the three are troubled much with insects or disease.

Odontoglossum cirrhosum. — This comparatively new species is described as one of the most lovely Orchids we possess, and we think it deserves the compliment; but what gives it most value is that it is a free grower, and prefers an intermediate house, or even a warm greenhouse, to the stove. It would perhaps be better wintered—at least in the last-named structure—after its bulbs are perfected, otherwise they seem inclined to make a second growth if left in heat. Its free growth is remarkable. Living Sphagnum chiefly and bits of peat mixed seem to be all that it requires in the way of compost. The plant delights in plenty of moisture at the root during summer, and should not be dried off altogether in winter, but the soil should be kept sufficiently moist to keep the Sphagnum alive. The leaves are not nearly so sensitive to damp as O. vexillarium. It is, in short, an uncommonly hardy intermediate-house plant, of easy culture, and should be in every collection of flowering plants.

Cypripedium insigne, insigne Maulei, barbatum, venustum, and niveum.—All these except the last are robust-growing kinds, easily kept in health; and their flowers, which are abundantly produced, are very ornamental and useful for cutting. The old insigne is an exceedingly free grower and flowerer, and Maulei is a very superior variety of it. They all grow freely in fibry loam, peat, sand, and charcoal, and should be potted tolerably firm, and well watered while they are growing. To attempt growing them in the usual Orchid compost, consisting of Sphagnum and poor peat, is simply to half-starve them. The pretty little C. niveum is a slow rather than a weak grower, and requires the same treatment as the others. Those named are perhaps as cheap and as easily procurable as any; but there are a number of excellent varieties, both new and old, which are equally good growers. Among some of the fine kinds may be named—Dayanum, Argus, Domini, Sedeni, Fairieanum, lævigatum, Roezli, Pearci, Lowi, and villosum.

Zygopetalum Mackayi and crinitum.—Both of these are free-growing plants and sure bloomers, and succeed in fibry loam, peat, Sphagnum, and charcoal. The pots should be well drained, and in potting the plants must be set pretty well up above the rim of the pot, and the compost packed neatly and firmly up to the base of the bulbs to keep them erect. Stove heat and plenty of water at the root during the growing season will suit them, but moisture must be nearly withheld during the winter.

Miltonia spectabilis and its Varieties.—M. spectabilis is a beautiful and popular plant, of easy culture. It succeeds in the same compost as the above, but without the loam, and is best grown in a shallow pan. It does not require a very high temperature, and should be shaded from strong sunshine, which turns the foliage yellow. We have seen a good specimen growing in a Vinery under the Vines, where it stood for some time after the fire heat was withdrawn, and was as green as Grass, and healthy, and flowered well.

Lycaste Skinneri.—This is another of those popular Orchids which is recommended for general culture. There are numerous varieties of it, all of which are more or less attractive. It requires ordinary stove treatment, and a compost of Sphagnum, peat, and charcoal to grow in, and good drainage. It should be grown extensively.

Cool Orchids (Odontoglossum).

Lælia purpurata.—A magnificent Orchid, and one not very difficult to grow; it thrives in the same kind of compost as the Lycaste, and requires much the same treatment in other respects.

Here ends our list. No doubt it might be added to; but we have chosen to enumerate only a few of the easiest cultivated and really useful species, and such as might be added to any mixed collection of stove or intermediate-house plants. When anything like a collection is attempted, and a house cannot be set apart for them, the best plan is to devote a shelf of the stove to them alone, in order that their wants may be more conveniently attended to, putting such as require most heat at the warmest end, and *vice versâ*. As regards moisture and shading,

&c., what will suit the generality of stove plants will suit the Orchids; but, as far as practicable, the latter should have the special treatment they require as regards watering and potting. S.

ANSWERS TO QUERIES.

2300.—**Insects on Plants.**—When plants become much infested wiih red spider, the foliage should be well sponged. This pest only appears when the atmosphere is very dry, and may easily be hindered from establishing itself if sufficient moisture is created in the structure either by means of damping down the paths and stages or frequently syringing the plants. The red spider makes its home on the under surface of the leaves; it is therefore advisable to occasionally thoroughly moisten every portion of the foliage. One or two good washings weekly will do more to dislodge the enemy than two or three daily sprinklings. The great point is to keep this plant foe at a distance by maintaining those atmospherical conditions which are inimical to its welfare. It may be safely asserted that where red spider has been allowed to spread, but little pains has been taken to ensure the conditions necessary to the welfare of the plants. In a healthy genial growing atmosphere red spider cannot live. Scale is often the result of indifferent culture—a starved, unhealthy specimen being more liable to be infested with it than vigorous-growing plants. At the same time, there are certain plants peculiarly susceptible to its attacks. Its appearance must be watched for, clearing each insect off before it has time to breed. When a plant has become much infested, only time and patience will clear it.—J. C.

2301.—**Propagating Gloxinias.**—The best time to propagate is as soon as the flowers fade. Take off healthy leaves, cutting them off with a sharp knife at the joint where the leafy portion terminates; reduce their proportions by cutting away about a third of their length, and insert them in fibrous peat or Cocoa-nut fibre round the edge of a 4-in. pot; keep them in a close house, maintaining the soil in a moist condition, avoiding heavy waterings; by the end of the season little bulbs will have formed at the base of the leaves. Gloxinias may also be propagated from seed to be sown in early spring in a warm house; the soil should consist of well-sanded peat, should be pressed down firm, and watered, the seed sown thinly thereon, and very slightly covered; cover the pan with a pane of glass until the young plants appear.—J. C. B.

2287.—**Autumn and Winter Flower-beds.**—The list of plants flowering during the late autumn and winter months is not a very extensive one. There is the large and varied family of Chrysanthemums, which flower until the advent of severe weather. There is Lobelia fulgens, with beautiful scarlet flowers; and the extremely effective Anemone japonica and its white variety. A good arrangement for an autumn bed would consist of Chrysanthemums in the centre, around them a row of Lobelias, then Anemones, mixing the colours, next to them Christmas Roses, finishing off with a neat edging of Cerastium tomentosum.—J. C. B.

2236.—**Acacia and Pampas Grass.**—As soon as the Acacias are large enough to handle, pot them off singly into small pots in a compost of half leaf-mould and half loam, adding thereto a good portion of silver sand. Place them in a frame or greenhouse where they may be kept rather close for a time until fairly established. If the pots get filled with roots, in the course of three or four weeks the plants may be shifted into the next-sized pot; otherwise it will be better to defer re-potting until next March, when they may be placed in 2½-in. pots. During the summer months keep them under cover, sprinkling in hot weather, and shading from hot sun. During September expose to the full air both night and day, merely sheltering from heavy rains; and towards the latter end of the month place them in a cool greenhouse, ventilating freely in favourable weather, but avoiding cold draughts. The Pampas Grass, when large enough, should be pricked out in the open air in a nice mellow piece of soil. Plant them about 9 in. apart, keep them clean during the summer, and water in hot weather. If well attended to, they will make nice little plants by the autumn, and may then be planted in any desired situation. It would, however, be preferable to allow them to remain in the nursery bed until spring, as there it will be an easy matter to protect them—a necessary precaution in the case of such young plants. April and May are good months for transplanting; if moved before growth commences the roots are apt to perish.—J. C.

2295.—**Lily of the Valley not Flowering.**—To obtain good flowering roots of Lily of the Valley the soil intended for their reception should be well stirred, richly manured. and if of a heavy nature, should in addition receive a dressing of leaf-mould, wood ashes, or some such light material. The Lily of the Valley revels in a free porous soil; at the same time where the natural staple is of very sandy or parching description it will be much benefited by the addition of a portion of good loam. The ground intended for planting should be deeply dug anywhere during September, laying it up roughly for a week to sweeten. It should then be gone over again with a steel fork, working in the manure and any other material which it may be considered advisable to apply, and breaking all the lumps. By the middle of October the roots may be planted in lines, some 18 in. apart, allowing 6 in. from plant to plant. Choose a dry time for planting, and tread each sort in firmly. In dividing the roots keep the strongest crowns by themselves, as if planted together, less difficulty will be experienced should it be desired to select any for pot culture. The following March, hoe well between the rows, and mulch with some manure, Grass, or litter of some kind. Keep the plantation free from weeds during the growing season, and water copiously in hot weather. This treatment cannot fail to produce abundance of flowers of excellent quality.—J. C., *Byfleet.*

2251.—**Plants for Sunless Windows.**—Ferns, Mosses, and other foliage plants will grow in the north window, or, to come to details, try the following:—Ferns—Asplenium marinum, Lastrea filix mas cristata, Polystichum angulare cristatum, Scolopendrium vulgare multifidum, Adiantum pedatum, Cyrtomium falcatum. Moss—Lycopodium denticulatum. Grass—Isolepis gracilis. Foliage plants—Cyperus alternifolius, Dracæna indivisa, Farfugium grande, Ficus elastica, Grevillea robusta, Coprosma Baueri, Abutilon Thompsoni. Many of the dwarfer forms of Cacti will do, if kept dry and moved into the sunshine a month or two to ripen their growth. All the Mimulus family will flower in the north, including Harrison's Musk.—E. H.

2247.—**Rose Trees not Growing.**—It is not good practice to cut back and repot at the same time. The check has probably been too severe, as just at the time leaves are required to stimulate the roots into activity they are absent. Either repot and get the roots into action before pruning, or else prune first and get up a new growth before re-potting. The result in either case would have been better, but this advice is like locking the stable door after the steed has been stolen. The plant will probably recover sooner if placed in the open air, and not watered too much—just merely keeping the soil moist till it is again growing vigorously.—E.

2269.—**Pruning Fruit Trees and Shrubs.**—The best time to prune pyramid fruit trees is from Midsummer to the first of September, commencing at the former date to stop robust growths to four leaves, and thin out others where too thick; and finish off at the latter date by pruning away all useless surplus wood, instead of leaving it to be done in winter. In pruning there is, or should be, a happy mean between leaving trees to run wild and pruning so close as to cripple them; and this can only be arrived at by studying each tree and treating each case on its merits separately. All evergreen shrubs should be pruned in spring, just as the sap is rising; but the use of the knife should not be abused. Simply stopping runaway shoots is in most cases all that is required. Where things have run wild, cutting down may sometimes be necessary.

2254.—**Plants for Window Boxes.**—I think I should use Harrison's Musk instead of the Golden Feather. The boxes need not all be planted alike, but Musk and Ivy-leaved Geraniums planted alternately along the front would have a pretty effect hanging over the blue boxes. Stocks, scarlet, white, and Pink Geraniums, with a few foliage-plants, such as Abutilon Thompsoni and the variegated Cocks'-foot Grass Dactylis elegantissima, would look well mixed with the flowering plants. The dwarf growing Tropæolums, with Nierembergia gracilis to hang over, will form a pretty combination. Some of the largest leaves should be picked off the Tropæolums to show the flowers to better advantage, as well as permit the Nierembergia to show itself—H.

2273.—**Shrubs for Cold Locality.**—The following list of shrubs will probably suit "H. P.": Forsythia viridissima; Hypericum calycinum, H. floribundum; Cerasus Padu's in the background; Lilacs, white and purple; Ribes sanguinea; Syringa; Daphne Mezereum; Venetian Sumach; Pyrus japonica; Spiræa ariæfolia, S. callosa; Laburnums; Thorn, Paul's Double Scarlet; Brooms, white and yellow; Honeysuckles; Deutzia gracilis, D. scabra; Cytisus elongatus; Berberis purpurea, B. aquifolium, B. stenophylla; Pernettya mucronata; Althea frutex; and Japanese Privet.—E.

2272.—**Gooseberry Trees with Rank Growth.**—Thin out the rank shoots now on the Gooseberry and Currant bushes to let in the sunlight and air to ripen the wood; and at the autumn or winter pruning thin out the growths a little more if necessary, but do not shorten those shoots which are left, and there will be an abundance of fruit. It is a great mistake to prune Gooseberries too hard on strong soils; their time and strength is frittered away in useless wood production when such is the case.—E. H.

2306.—**Ivy as a Border Plant.**—The broad-leaved Ivy should succeed if properly planted. The chief reason why it is not so much employed for edging as the small kind is that on account of its naturally rank growth; it does not form so neat a bordering. Stir the soil deeply, and if very poor or sandy add to it a little rotten manure. Plant any time now and water freely in hot weather. For this purpose we should prefer free young plants that had not been grown in pots. Strong shoots taken off now and laid in closely in a shady place would become well rooted by the autumn months. In planting bury the stem quite 9 in. in the soil; a large amount of fibres will then be produced with the effect of inducing a vigorous growth the first year. Plant thickly and peg each shoot down as it increases in length. In this manner a good thick edging will be formed by the second season.—C.

2250.—**Asparagus Beds.**—It need not cost anything extra if the land has hitherto been well cultivated. Somehow the idea seems to have taken possession of most people's minds that Asparagus is an expensive plant to grow. To trench the land up as deep as it will bear, at the same time well manuring it, is good practice, not only for Asparagus, but for all vegetables; and that is all that this plant needs. Plant in rows 3 ft. apart and 18 in. from plant to plant. The best way is to open trenches 6 in. deep and wide enough to lay the roots out straight. If the land is heavy, cover the crowns 1½ in. deep with the compost formed by the waste matters which accumulate at the rubbish heap; but let it be rotted down to mould. The cost of the bed will be just the cost of the plants if they have to be purchased, or the seeds if seeds are used. Although it is full late for both planting or sowing yet, good results have been obtained by late planting, if the plants are procured near, and water and mulching be well attended to. If two-year-old plants are used, some Asparagus may be cut the second year after planting.—E. H.

2323.—**Flies in Rooms.**—Being much pestered with flies in my smoking room, I hung a piece of net, 1-in. mesh, outside my window. I had read of this in a work on Egypt. I then by means of a leather flapper, 5 in. in diameter, tied to a piece of cane, killed about one hundred flies; and from that time to the present, many years, have never had a fly in the room, except a stray one coming in at the door. I found this so successful, that I had made a light deal frame with net, ¼-in. mesh, nailed on, and fitted to the windows of the drawing and dining rooms, and we never have a fly, but I found they came into the hall. I then had made a door frame,

put on to the front door with hinges, and a spring to keep the door shut on people going in and out, and we are now free from flies in the house. This was tried by hanging a net over the door of a dairy, and reported ineffectual, but the reason was, servants going in and out took flies in with them, and no doubt often kept the net away from the door. I can safely assert this plan certain, but at the same time regard must be paid to prevent servants especially from allowing the nets to be opened. In my drawing-room upstairs I have three windows in front, and I have a frame with ¼-in. mesh put on with hinges, so that the window can be cleaned; it is in two pieces, and I keep the window open to let in fresh air, the other two windows being kept shut. I have a Tobin's ventilator also in the room. For a bedroom I have adopted a most efficient ventilator. Instead of a wire gauze blind I had a frame made about 2 ft. high and ground glass inserted, and fixed inside at about 1 in. from the window; the lower part of the window is opened about 3 in., and the air comes in between the frame and window and goes up, causing no draught. It is as well to have a sand bag to put over the upper part of the sash, as the wind coming in there might cause a draught.—OLD INDIAN.

2252.—**Hardy Perennials.**—The following are the names of a few perennials that just occur to me, which may be sown in July and August. All such seeds may be sown as soon as ripe, that being their natural season:—Lupinus polyphyllus, L. macrophyllus, Foxgloves (spotted varieties), Dictamnus fraxinella, Linum perenne, Delphinium formosum, Veronica spicata, Lunaria biennis, Columbines, Antirrhinums, Anchusa italica, Rudbeckia Newmanni, Campanula pyramidalis, C. nobilis, Alyssum saxatile, Violas or Pansies, Doronicum Clusii, Primula japonica and others, Dracocephalum austriacum, Trifolium rubens, Hollyhocks, Sweet Williams, Centaurea montana.—E. H.

2255.—**Hollyhock Leaves with Red Spots.**—The red spots on the Hollyhock leaves are indications of a fungoid disease that has been destructive to that class of plants of late years, especially in dry seasons. Pick off the badly affected leaves and burn them, and wash or dip in a solution of Gishurst Compound, 3 oz. to the gallon, with ½ lb. of sulphur added to each gallon. This dressing should be repeated as often as necessary; and at the same time the plants should be encouraged to make new growth by mulching with manure and liberal supplies of water if the weather continues dry.—E. H.

2296.—**Drying Wild Flowers.**—Get as perfect specimens as possible of each plant; it should have good leaves, radical and upper; also flowers and, if possible, fruit or seeds. It is often well to have a second specimen having seeds. Spread it in as natural a manner as possible between sheets of stout blotting-paper, and leave it in press under a moderately heavy weight until quite dry, *i.e.*, from a few days to two or three weeks, tender plants taking a short time, woody ones longer. The blotting-paper must be changed if it gets wet. When dry fasten to sheets of white paper with narrow slips of gummed paper. "Lessons on Elementary Botany," by Professor Oliver (Macmillan), will give full information on the subject.—A LOVER OF FLOWERS.

2298.—**Flowers for Button-holes.**—Lantanas of various kinds, and Ageratums (both blue and white), Verbenas, Paris Daisies, Cuphæa platycentra, are all suitable subjects for the purpose. They will, however, thrive much better if grown fully exposed to sun and air. Plant them in a box and place the same on the window-ledge; they will flower profusely during the summer months.—C.

2268.—**Sawdust for Blanching Celery.**—Fresh sawdust will not do for blanching Celery, as it would—especially if from Pine wood—impart an unpleasant flavour. But when it has laid up in a heap for 12 months, I have used it with advantage, and the Celery turns out from it beautifully clear and free from speck or blemish.—E. H.

2246.—**Rhododendrons not Flowering.**—If the seed-pods are not picked off the plants immediately they have ceased flowering, bloom-buds another year need not be expected; this I have proved over and over again.—R. H. P.

2270.—**Bottom-heat for Frames.**—*W. S. J. D.*—The consumption of oil (petroleum) is 6 quarts; at 1s. per gallon, retail, comes to 1s. 6d. per week. The reason the lamp is made to hold two quarts is, lest by any oversight it might be left for more than thirty hours without being filled. Paraffin is cheaper, and is sold from 9d. to 10d. per gallon in Ireland.—PETROS.

2347.—**Camellias in the Open Air.**—Might Camellias grow out in the open air all the year round in the south of Scotland? and if so, should they be covered up in winter?—NITH. [When once established, we believe the Camellia would grow in the south of Scotland, as it is much hardier than many other shrubs generally planted.]

2348.—**Marechal Niel Rose.**—Will a young Maréchal Niel Rose 3 ft. high flower this year planted on back-wall of greenhouse?—J. H. T. [We should say not; but it might flower early next spring.]

2349.—**Plunging and Watering Balsams.**—Would Balsams flower well if plunged in sawdust kept damp in a greenhouse? Being from home during the day, I have sometimes found them flagging on my return. Is liquid sheep manure good for them in a strong state? and how often should it be given?—PETROS. [Ashes, Cocoa-nut fibre, old tan, or hops, would be better than sawdust, as the latter is apt to breed fungus in the soil. You cannot have anything better than liquid sheep manure for watering them with. Apply it in a weak state at first two or three times a week, and gradually increase its strength.]

2350.—**House for Tuberous Begonias.**—As I intend building a glasshouse, and devoting it to the culture of tuberous Begonias, would you say which is the most suitable situation for such a structure?—J. H. S. [If a span-roofed house, let the ends face north and south; if a lean-to, south, you cannot get too much light and sun in early spring; in summer you will have to shade the plants slightly. You can, however, grow very good Begonias in a house with any aspect.]

2351.—**Planting Creepers.**—At what season of the year should I plant Clematis and other creepers to climb on some old Apple trees?—E. H. B. [In spring or autumn.]

2352.—**Strawberry Culture.**—Last autumn I planted some Strawberry runners, and this year only about two-thirds of them are flowering. Ought I to pull the non-flowering ones up and replace them with fresh plants? or, will they flower and fruit next year when they are stronger? My soil is very sandy, but I want to get them as fruitful as I possibly can. When should manure water be applied to them?—TREMADOC. [As the plants are weak, it would be well to give them another year. Apply manure water as soon as the fruit is set.]

2353.—**Cucumbers Fruiting.**—Will Cucumber plants bear fruit in a frame without anything being done to them? I have heard that there is what they call a male and female bloom, and that there is some mode of treatment without which they will not bear any fruit.—XERXES. [They will bear fruit freely enough at this time of the year without artificial fertilisation, which is the treatment you have heard of. In winter it is sometimes necessary.]

Melons Ripening.—*Constant Reader.*—You will easily tell when a Melon is ripening by the perfume it will emit on opening the frame in the morning. When this is observed, examine the fruits; and when you find them begin to crack round the base of the stalk cut them at once, and put them in a cool place till wanted.

Young Vine.—*J. H. T.*—If the Vine is growing rapidly it will not injure it in the least to cover up part of the rod at the base with soil. It will soon emit roots from the stem and assist growth; but it would be best to do it a little at a time—say 6 in. of soil added would be plenty at once.

Camellia Leaves Curling.—*C. H. W.*—Perhaps they are dry at the root. Place the pots in a tub of water for half an hour or so, and if the plants have made their growth, place them out-of-doors in a shady situation, but not under trees. Syringe them daily throughout the summer.

Moving Virginian Creeper.—*E. S.*—If the plant is a small one it might be moved now if well watered first, and dug up without breaking the soil from its roots; but if a large plant you had better leave it till the leaves die down in autumn.

Gladioli Leaves Turning Yellow.—*Learner.*—The weather may have something to do with it. Be careful not to get the soil in the pots sodden with over-watering, and be equally careful not to let it get dust, dry.

Vine Leaves Shrivelling.—*Novice.*—The leaf sent appears to be completely scorched up. It also appears to have been grown without ventilation. Give plenty of air. If the soil is well drained give plenty of water; not often, but when you do water, give a thorough soaking.

Herbaceous Plants.—*A Lady.*—Mr. Ware, Hale Farm Nurseries, Tottenham; Mr. Parker, Exotic Nursery, Tooting; Messrs. Backhouse & Sons, York; Messrs. Dickson & Sons, Chester; or any other good hardy plant nursery.

Calystegia pubescens.—*A Lady.*—This is a hardy perennial. If you obtain plants at once they will flower well this season. It is easily increased by division of the root in spring.

Insects in Peas.—*J. B.*—It is a common thing in Peas this year. The insect in its grub state is in the Pea before it ripens in autumn, and comes to life in spring. There is a small hole in each Pea containing an insect.

Pelargoniums with Small Blossoms.—*E. G. J.*—If your plants are in a shady place, the blooms are sure to be poor; Pelargoniums want plenty of sun.

Cleaning Flower-pots.—*One who Wants to Know.*—The best method we know of is that described in GARDENING, May 1.

Platycerium alcicorne.—*J. C.*—Syringe it well daily, and occasionally throw it into a tank of water, and let it remain for a quarter of an hour.

Centaurea cyanus minor.—*M. G.*—The seed of this is easily obtained at any good seed-shop.

Brugmansia.—*M. G.*—From any good London nursery; we do not know the price.

Young Beginner, Rugeley.—The question asked can only be of interest to yourself, and if you will send us your address we will advise you.

W. Thompson.—Your question is altogether out of our way.

Fuchsia Riccartoni.—*G. G., Manchester.*—Apply to Messrs. Backhouse & Sons, The Nurseries, York.

C. F.—The Camellia leaf is scorched. Shade the plants from the sun, and admit abundance of air.

Auriculas Out-of-doors.—*A Lady.*—A top-dressing of good mould will do the plants much good.

Tomatoes.—*G. S.*—See GARDENING, May 22 of this year.

A. S. W.—If of any practical value.

Happy thought.—See our advertising columns.

Names of Plants.—*J. B.*—The Fern is Pteris serrulata. We cannot name such flowers as Fuchsias or Geraniums.——*A. M. T.*—1, Centaurea jaca; 2, Goutweed (Ægopodium Podagraria).——*St. R. B.*—1, The scented Woodruff (Asperula odorata); 2, Centaurea montana; 3, Aquilegia vulgaris.——*H. C.*—1, Symphytum asperrimum; 2, Veronica (alpine species); 3, Veronica repens.——*Tyroni.*—Equisetum palustre; 2, Listera ovata; 3, Sagina procumbens; would do for a rockery.

QUERIES.

2354.—**Honeydew.**—It is well known that the aphis is an invariable precursor of honeydew, but it is not so well known how it is produced. One authority declares it to be ejected from the insect itself, and that it is "erroneously supposed to be an exudation from the leaves on which it is found." Another says, "The strange notion is entertained that this matter (honeydew), is exuded by the aphis itself, when in reality it is emitted through the upper pores of the leaf." Can any doctor among your readers decide this knotty point for me?—H. D.

2355.—**White Flowers for Cutting.**—I propose to plant out in cold frames Gladiolus Colvilli albus, and Narcissus poeticus fl.-pl. Are they perfectly hardy under this protection? and how many of each would go in a space 16 ft. by 6 ft.? What month should they be planted to get them in as early as possible? and is there any other white bulbous flower that would do and sell better under same conditions?—AMATEUR.

2356.—**Spotted Mimuli.**—I have one of these plants—or rather four or five, in the same 8-in. pot—whose branches have in ignorance been allowed to grow to the length of about 20 in., in consequence whereof the plant had an unsightly, straggling appearance; and, with a view to improving it, I about ten days ago surrounded it with a supporting wire guard about 18 in. high, pinched off the point of each branch to stop further length, administered soot-water to the roots, and removed it from a small window facing east, without much sun, to a much larger one facing west, and since then the plant has flagged. Can any one account for this? and could I safely cut the plant down to within 5 in. or 6 in. of the edge of pot? and could plants be raised from such cuttings? It was fresh and flowered freely up till then. I removed the seed pods at same time.—FLY ORCHIS.

2357.—**Making a Pond.**—Can any reader kindly give me any information to enable me to construct a small round pond, say 6 yards round and 4 ft. deep? How must the bottom and sides be coated to keep the water from getting away. Soil is clayey.—CASSIOWARY, *Edmonton.*

2358.—**Camellias Out-of-doors.**—Will some one tell me if Camellias would succeed near Bedford in the open-air? Our Laurustinus this year were all cut down to the ground. Also please give the names of a few of the hardiest kinds, with hints as to cultivation, soil, when to be planted &c. Do they require covering in winter?—W. G. LOVELL.

——I intend to act on "Omega's" advice, and plant Camellias out-of-doors. Will some one kindly quote twelve of the best various colours, hardy, and best fitting for the purpose, and the proper time for planting out?—W. S., *Cornwall.*

2359.—**Cool Orchids.**—When should the following Orchids flower in a cool house: Epidendrum vitellinum majus, Dendrobium japonicum, Lælia autumnalis, Pleione Wallichi, Odontoglossum Rossi majus, O. Insleayi leopardinum, and O. cirrhosum? What should be their treatment now as regards watering, &c.—L. N.

2360.—**Guano for Flowers, &c.**—I have an equal quantity of guano and superphosphate of lime mixed together. How many ounces of this mixture should be put into a gallon of water to make liquid manure for flowers? and what proportion of dry earth should be mixed with this mixture of guano and superphosphate, so as to enable one to sow it broadcast in the garden?—ROYSTON SUBSCRIBER.

2361.—**Winter Lettuce.**—Will some reader inform me of the two largest and best Cabbage Lettuces to stand the winter?—J. B. F.

2362.—**Making a Vinery.**—I am erecting a small span-roof Vinery, 24 ft. by 12 ft. I wish to know if it is necessary to make a border for the Vines, as I am building it in a kitchen garden, where the soil is, I imagine, pretty rich; subsoil is dry, being on limestone rock. If necessary to make a border, when is the best time to do it, and how? How should the house be heated—by flue, or hot water?—AGRICOLA.

2363.—**Fruit Trees for South Coast.**—Will any reader kindly tell me the names of half-a-dozen Pear and Apple trees, also Plums, suited to grow on the south coast in Sussex? and also if there is any good fruit nursery in this county?—EASTBOURNE.

2364.—**Standard Roses in Pots.**—I wish to grow some standard Roses in a greenhouse for decoration. Would any reader kindly give me the names of a few good sorts for that purpose?—MIDDLESEX.

2365.—**Malmaison Pinks.**—Will your readers tell me the best way to grow the Souvenir de Malmaison Pink, so as to ensure good flowers. Last year we had fine plants and promise of flowers in the open border, but the wet season spoiled all the flowers as fast as they began to come out. We therefore took the plants up, potted them in good loam, and kept them in a cold frame during the months from November to March. They were in March put in a greenhouse for forcing—the temperature about 60° to 65°. After the buds were formed and the flowers well advanced, the stems of all the plants became dry and brown, and many of the plants died, evidently from the stalks just above and some below the soil rotting off. The plants were kept moderately damp, and twice had liquid manure. Any information on the right culture of this plant will be gratefully received.—BURY ST. EDMUNDS.

2366.—**Worms in Gardens.**—Can any one inform me what is the best means of getting rid of worms in a garden? Although I pick out all I can when digging the ground, yet my Onion and other beds are completely overrun with them. The beds are a mass of holes, and I suspect it is owing to the worms that my Onions are so thin. I suspect also that they get at the Peas, Scarlet Runners, &c., when sown, by the scant produce I have. B. TAYLOR.

2367.—**Mortar for Greenhouse Flue.**—Will any of your numerous readers kindly inform me how to make a good adhesive mortar for fixing a flue in a greenhouse? I find many kinds I have used crack as soon as they are exposed to the heat. I want a mixture that will not do this.—J. W. K.

2368.—**Grafting Wistarias.**—In my garden against a west wall is a very fine specimen of Wistaria sinensis growing to the eaves of a tall building, and covered with its beautiful lavender blossoms, though they are rather damaged by late frosts. In the catalogues of some of the leading nurserymen are the names of no less than eight varieties of this beautiful climber, of which we may get small plants, but not sufficiently advanced to blossom, and therefore the purchasers are left quite in the dark as to whether the varieties are worth cultivating or not. I should like to have the whole of these kinds grafted or budded on my strong-growing sinensis, if worth the trouble. I think the effect would be very striking if judiciously done, but where are the blossoms to be obtained? If the editor of GARDENING ILLUSTRATED will kindly apply to his very numerous subscribers to send one good raceme of each variety of these beautiful plants to his office, and will give his opinion as to the merits of each variety, truly he will be conferring a great boon on all possessing large specimens of Wistaria sinensis, for then the lucky owners can have the whole series grafted or budded on one tree, which would give a most pleasing variety to the beautiful lavender blossoms of the main stock I have thought of this for years, but could never see my way until the article on the Wistaria appeared in GARDENING ILLUSTRATED lately, and the plants should be all in full blossom now. —F. NASH.

2369.—**Children's Flower Show.**—We, the teachers of a Sunday school in this town, are going to hold a flower show this year some time in September and as the majority of the exhibitors will be children, I should like to have some practical advice as to the things most likely to succeed. We are just starting the thing. In your advertising columns I see Balsams at 1s. 6d. dozen. Now, I think that will be a thing our scholars can grow, as they do not require heat after the seed-pan treatment. Will some one give directions how to treat them, as the majority of amateurs grow them as long unshapely specimens? Asters, again, may, I think, do; and will Fuchsias struck now be plants by that time? These are my own thoughts, but I humbly ask for advice in the matter. I myself shall go in for a vegetable collection. Can any one give me advice when to plant for that time? I have a large garden, can put up a frame. and willing to give time as long as I can succeed. Can we manage Phlox Drummondi from seed sown now? Will it bloom in pots for September?—W. G.

2370.—**Sparrows Eating Pyrethrum.**—Can any one tell me how to prevent sparrows eating my Pyrethrum?—ONE WHO WANTS TO KNOW.

2371.—**Prickly Comfrey.**—Would Prickly Comfrey be good as food for hens, ducks, and pigs? and if so, what is the best way of preparing it?—T. J. S.

POULTRY.

Nests for Sitting Hens.—In making a nest for a sitting hen it is best to make the nest on the ground in the corner of an out-house, stable, or in the yard, and away from the other hens: a large turf of Grass placed at the bottom, and on the top of this some hay or straw, and with a few bricks put round to keep the eggs from rolling out. If the weather is dry, the whole—eggs, turf, and hay—should be well drenched two or three times a week with slightly warm water. We prefer taking the hen off the nest each morning to feed and dust, rather than leaving her to come off of her own accord.

Best Kind of Fowls to Keep.—As T. T. Ewing requires a hardy and prolific fowl, we should say try the cross between the Brahma and Dorking—a Dorking cock and Brahma hens. The offspring of these grow very quickly, are hardy, and make splendid table fowls, and are excellent layers. Hens seldom lay away if a sufficient number of nests are provided and a dummy egg is placed in each nest.

Black Combs.—The colour in the comb often changes if the weather is cold and the atmosphere dry but with a warm shower they soon regain that coral redness which is a sign of good health and condition. Birds also become white in comb as they are about to discontinue laying, but as "F. F.'s" fowls are healthy and lay well, there cannot be anything the matter with them.

Unfertile Eggs.—We should advise "A. P. K." to change the cock, and let the hen have all the run possible.

AQUARIA.

White Slime on Fish.—The white matter may arise from overcrowding, too much sunlight, or the presence of decaying matter in the water. Take the fish as soon as it appears, and put them in a soup plate, with a few stones at the bottom to rub against, and place under a gentle flow of water for a few hours. More snails might help to prevent it if it arises from the last-named cause.—T. CHADBURN.

Covering Aquarium.—If the aquarium is exposed to dust, or if you have any beetles in it, it is best covered. Gravel well boiled will answer. If the bottom is not deep, plant in pots.—T. C.

Water for Aquarium.—Soft water is best, but the ordinary drinking water will answer. If properly stocked you need not change the water for twelve months.—T. C.

Caddis Worms.—Your caddis will feed themselves if left alone, and by-and bye they will close up the mouth of their cases, and go into the "pupa" state, after which they will emerge in the form of a four-winged fly.—T. CHADBURN.

Fishes Fins.—Can any reader say why some of the fish in my aquarium do not raise the fin on their backs? I think it must be a sign of ill-health. My aquarium is a propagating glass, 13 in. in diameter, with sand and shingle, and a few plants in, two or three snails, three gold fish, two roach, and two minnows. I do not change the water, only take a little out with a siphon, and add fresh with a fine rose watering pot, and I do not feed the fish. I shall be very much obliged for any information.—CAMPION DAWSON.

THE HOUSEHOLD.

Asparagus Cooking.—A hint about boiling Asparagus is worthy of mention, since the proper method is rarely followed by English cooks. Asparagus of the stouter sort, always when of the "giant" variety, should be cut of exactly equal lengths, and boiled, standing ends upward, in a deep saucepan. Nearly 2 in. of the heads should be out of the water—the steam sufficing to cook them, as they form the tenderest part of the plant: while the hard stalky part is rendered soft and succulent by the longer boiling which this plant permits. Instead of the orthodox twenty minutes allotted to average Asparagus lying horizontally, in the English manner, which half cooks the stalk and overcooks the head, diminishing its flavour and consistence, a period of thirty or forty minutes, on the plan recommended, will render fully a third more of the stalk delicious, while the head will be properly cooked by the steam alone. One reason why it is not uncommon to hear the best produce of the fields of Argenteuil insufficiently appreciated here, and our own Asparagus preferred, is, that the former is rarely sufficiently cooked at English tables.

Peas Flemish Fashion.—For the following receipt we are indebted to Sir Henry Thompson: Put 1 pint of Peas, 1 oz. of butter, and ½ lb. of flour, into a stewpan; stir well over the fire until the butter is melted, add a little Parsley, three or four small Onions cut up, and two Lettuces sliced rather fine, and ½ pint of Stock, a teaspoonful of sugar, and some salt. Put on the lid, and stew for half-an-hour. Take out the Parsley, add a little more butter, and serve.

Cooking Green Vegetables.—To prevent green vegetables from having an unpleasant scent when cooked put them into plenty of boiling water with a little salt, and throw on the top of the water a stale crust of bread, and let it remain in the water till the vegetable is cooked.—DOT.

FLOWER SHOW AT KENSINGTON.

THOUGH in many respects the four days' show which was opened at South Kensington on Tuesday last was inferior to the corresponding exhibition last year, it was nevertheless a good one, the classes on the whole being tolerably well filled, and for the most part well represented. The absence of the fine banks of Clematises which formed a noteworthy feature last year was conspicuous; there was only one group of pot Roses (probably owing to the show being nearly a fortnight later), and this, added to the remarkably poor show of Azaleas, gave the large tent a subdued, if not a sombre appearance, more especially as the places of these bright-coloured subjects were filled by banks of fine-foliaged plants relieved by very little flower. A four days' show ought to be a good one, but probably it would be better if the time was curtailed by a day or two, for both private and trade growers do not care to exhibit valuable plants for so long a time; for instance, not a single exhibit came from Messrs. Veitch & Sons' nurseries, which generally contribute largely to the display; and the absence of other fine collections was noticeable. Opposite to the entrance of the large tent Messrs. Radclyffe & Co., High Holborn, exhibited a display of Ferns on rustic rockwork, at the top of which was a statuette fountain. A group of Roses from the Cheshunt Nurseries occupied a bank at one end of the tent, while the opposite one was devoted to fine-foliaged plants, which were unusually fine, and produced a grand effect. The Roses, from their elevated position, presented a fine appearance. The central mounds were occupied by show and fancy Pelargoniums on the one side, while on the other was a fine bank of Coleus and other fine-foliaged plants from Messrs. Carter, Holborn, backed by a fine group from Mr. Bull. The groups of plants arranged for effect were unusually numerous, one class occupying a large space in the large tent, as did also the specimen stove and greenhouse plants, of which there were about a dozen collections. The non-competitive groups of plants in the large tent were very effective, and notably that of the General Horticultural Company, which consisted chiefly of their fine hybrid Dracænas, each of which formed a handsome specimen. One half of the long tent leading from the large one was devoted to the ten collections of Orchids, the tuberous-rooted Begonias, hardy flowers, &c.; while the other half nearest the council-room was occupied by fruit and vegetables (of which there was a remarkably fine display)—cut flowers on one side, and new plants and groups on the other. Miscellaneous exhibitions were numerous, but amongst them were fewer implements, appliances, and structures than usual.

Horticultural Shows.—It has often occurred to me that the advantages derived from these exhibitions would be much more decided if the weight of some of the prize fruit and vegetables were made known. At a small show prizes are won, in Strawberries for instance, by fruit which is nothing like what might be grown; and the only criterion of excellence in size which the people of the district have is that afforded by the prize-winning dish of fruit. I would suggest, if the editor of GARDENING is willing, that the secretaries of some of our exhibitions should have the prize exhibits weighed where practicable, and send the number of fruit exhibited in the prize dish, with their weight, for insertion. We should thus be able in out-of-the-way places like where I live to form a better idea of what real excellence is.—TREMADOC, *North Wales*.

COVENT GARDEN MARKET.

WHOLESALE PRICES.

Cut Flowers.—*Per dozen bunches.*—Anemone, 2s to 6s; Azalea, 4s to 9s; Cineraria, 6s to 12s; Ferns (various), 3s to 9s; Heliotrope, 6s; Lily of the Valley, 4s to 12s; Lilac, 2s to 8s; Mignonette, 4s to 9s; Narcissus, 6s to 12s; Pelargoniums (zonal), 3s to 6s; Pelargoniums (large flower), 6s to 12s; (double), 6s to 12s; (Rose-scented leaf), 6s; Spiræas, 6s to 12s; Tropæolums, 1s to 3s; Tulips, 4s to 9s: Violets (blue), 1s to 2s.—*Per dozen flowers.*—Abutilon, 4d to 6d; Arum Lilies, 3s; Tree Carnations, 1s 6d to 3s; Eucharis, 4s to 6s; Gardenias, 2s to 8s; Roses, 1s 6d to 6s.—*Per dozen sprays or trusses.*—Bouvardias, 1s 6d to 3s; Fuchsias, 2s to 4s; Primulas (double), 9d to 1s; Stephanotis, 2s 6d to 4s.

Plants in Pots.—*Per doz.*—Arum Lilies, 9s to 12s; Adiantum cuneatum (ordinary), 6s to 18s; Begonias (flowering), 6s to 12s; Begonias (fine-foliaged), 6s to 12s; Bouvardias, 12s to 18s; Cineraria, 4s to 12s; Daphne indica, 4s to 6s; Dracæna (green-leaved kinds), 12s to 30s; Euonymus, 4s to 12s; Euonymus (variegated), 6s to 18s; Ferns (greenhouse and stove, various), 6s to 18s; Ficus elastica, 18s to 60s; Fuchsias, 6s to 12s; Gardenias, 24s to 36s; Lily of the Valley, 12s to 24s; Mignonette, 6s to 9s; Nasturtium, 3s to 6s; Palms (small), 18s to 60s; Pelargoniums (fancy), 9s to 24s; Pelargoniums (scarlet), 4s to 9s; Pelargoniums (double), 6s to 12s; Roses (hybrid perpetual), 12s to 24s; Spiræa japonica, 6s to 18s; Selaginellas, 3s to 4s; Virginian Creepers, 6s.—*Per pair.*—Maiden-hair Ferns (large), 4s to 7s; Palms (large), 15s to 42s; Amaryllis, 1s 6d to 3s each.

Fruit.—Apples (culinary), per bushel and barrel, 9s to 30s; Cobs and Filberts, per 100 lb, 120s; Grapes (English hothouse), per lb, 2s to 6s; Lemons, per box, 30s to 35s; Oranges (various kinds), per 100, 8s to 16s; Pomeloes, per dozen, 3s to 6s; Pine-apples (St. Michaels), each, 5s to 15s; Pine-apples (English hothouse), per lb, 1s 6d to 2s; Strawberries (early forced), per oz, 4d to 6d.

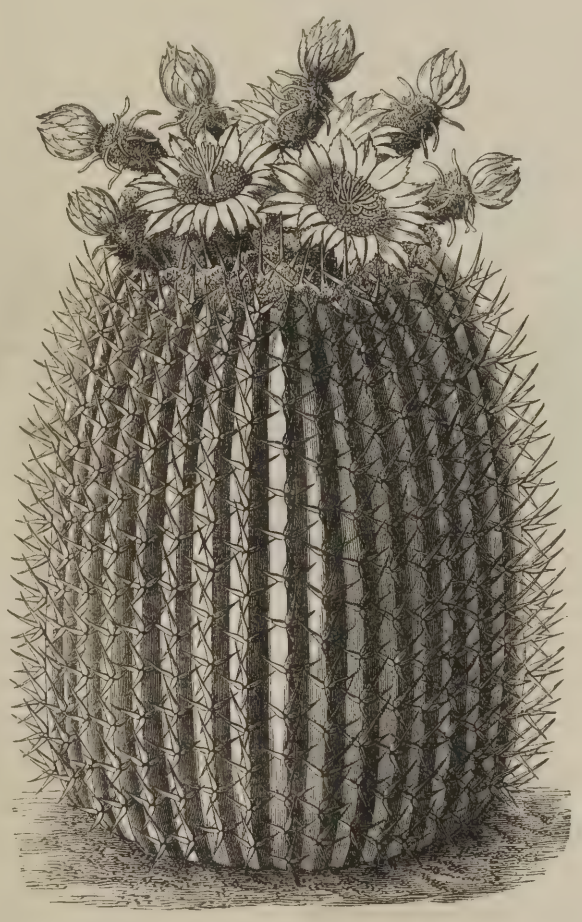
Vegetables.—*Per 100.*—Asparagus, 3s to 5s; French Beans, 9d to 1s. *Per dozen bunches.*—Carrots (outdoor), 4s to 5s; Watercress, 9d to 1s; Leeks, 1s 6d to 3s; Mint, 4s to 6s; Parsley, 6s; Turnips, 1s to 1s 9d; Radishes, 9d to 1s; Herbs, 2d to 6d. *Per doz. punnets.*—Cress, Mustard or small salad, 2s. *Per dozen.*—Cucumbers, 4s to 7s; Endive, 2s to 3s; Lettuce, 9d to 1s. *Per bundle.*—Horseradish, 3s to 6s. *Per lb.*—Shallots and Garlic, 6d; New Potatoes, 2d to 5d. Broccoli (Cornish) per crate, 10s to 18s; Broccoli (Sprouting), per bushel, 2s 6d; Savoys, per score, 5s; Chervil, per punnet, 3d; Corn Salad, per half-sieve, 2s; Mushrooms, per pottle, 1s 3d to 1s 9d; Potatoes (general store, round kinds), per ton, 100s to 200s; Kidney, per ton, 120s to 180s; Parsnips, per tally, 5s to 7s; Rhubarb (per dozen bundles), 2s to 3s; Spinach, per half-bushel, 2s 6d; Tarragon, per bunch, 6d.

GARDENING
ILLUSTRATED.

VOL. II.—No. 68. *SATURDAY, JUNE* 26, 1880. PRICE ONE PENNY. REGISTERED FOR TRANSMISSION ABROAD.

CACTI FOR WINDOWS AND GREENHOUSES.

Most people are acquainted with the tall-growing free-flowering Cacti, or Phyllocactus as they are botanically called, of cottage windows—plants which require only a sunny place and a little water sometimes to make them expand their blossoms, which in texture and brilliancy even the choicest Orchids cannot rival, but everyone is not aware that there are many other very different forms of Cacti, which may be grown with little trouble in windows and greenhouses, and which are a source of interest on account of their peculiar forms, and at the same time produce brilliant blossoms. Nearly all kinds of Cacti may be bought in a miniature state in Covent Garden or elsewhere, and if carefully tended they will in time develop into something like the plants represented in our illustrations. "Cacti are more curious than beautiful," say some. "What freaks of Nature these are!" say others, alluding to the plants in the succulent house at Kew, a house that everyone interested in Cacti should not fail to visit; others think all Cacti beautiful, and derive as much pleasure from them as do other amateurs from collections of other kinds of plants. The so-called night-flowering Cereuses rank amongst the finest of all flowering Cacti. The plants belonging to this class are climbers, and do best in a warm greenhouse, in a soil consisting of good rough loam and peat, with a dash of sand in it. Where it is necessary to move them about, a good plan is to grow them on an old Fern stem, or to get a wire cylinder and fill its centre with Moss and peat for them to root in; and if managed in this way they will do well in very small pots. To insure their flowering give them plenty of light, and do not fall into an error, which is unfortunately too common, viz., that of starving these plants. A drop of manure water at times will be found to be of great help, as will also surfacing the pots with some dried cow manure, and the syringe should be freely used during the summer time. The best flowerers are Cereus McDonaldiæ, creamy-white; C. triangularis, the same in colour and one of the largest; C. grandiflorus; C. hamatus, cream-coloured; C. Schrankii, rose; and C. pterogonue, a dwarf climber, with white flowers, the purest white amongst the Cactus tribe. Next come the Phyllocacti, just alluded to, all of which do well in a window or greenhouse. They may be trained on a trellis or in pots, with wires or sticks, but sticks are best, as the iron rusts and injures the roots. They like a rough but strong soil and plenty of water when growing, but when they have made their growth they should be well exposed to light and air. The best sorts are P. crenatus, white; P. Ackermanni, deep red; P. Edwardsi, rose; P. phyllanthoides, rose; and P. nitens, cream-coloured. To the more rigid forms of Cacti, Cereus vallidus, a kind with flowers of a pale rose colour, is a grand addition, and possesses a most delicate scent. All the kinds of Echinopsis have good flowers, and they are plants which can be grown very easily. Echinocactus Ottonis, yellow; E. mammillosus, white; and E. bicolor, rose and purple, are gems only requiring to be seen to be admired. The Tooth-pick Cactus depicted in our front page is one of the noblest of the genus to which it belongs. Its flowers, which are produced in profusion on the woolly apex, are straw coloured, their base or ovary being densely clothed with wool. The spines, which are in sets of from eight to ten, are very strong, and 1 in. or 1½ in. long, flat, and ribbed, and make very good and perfectly harmless tooth-picks. The plant grows freely in sandy loam, is moderately hardy, and will therefore grow in any airy window. The little dwarf Cactus (Echinopsis Pentlandi flammea) on p. 196 bears flowers 2 in. long, which are very showy. The plant itself, which is almost hardy, does not succeed in a hot dry house, in which it becomes affected by red spider, otherwise it grows freely. Mammillaria elephantidens, on p. 197, is a somewhat corpulent-looking species; each mamma is ½ in. long and 2 in. round, terminated by a cluster of from seven to nine pale brown spines. The flowers, which are large for those of a Mammillaria, are straw-coloured. Plants belonging to this genus are apt to become affected by red spider; therefore they do best in the open air during summer. They only grow about 6 in. high, and are, as a rule, favourites with those who are fond of Cacti. Mammillaria erecta, on p. 198, as its specific name implies, is an erect, narrow-growing plant, which attains a height of from 12 in. to 18 in. Its spines, which are yellow, are in whorls of from eight to twelve, the central one being



THE TOOTHPICK CACTUS (ECHINOCACTUS VISNAGA).

of the same length as the others. It has yellow flowers, and is nearly related to the Echinocacti. Cereus candicans, page 5, is a vigorous-growing kind, the stem of which, when about 5 ft. high, is often 3 ft. round, and the angles large and shallow, rendering the plant solid and heavy-looking. The spines, which are in sets of from twelve to twenty, are yellow, from 2 in. to 4 in. long, and very acute. It may be increased by offsets, which it produces freely from the base, and it is easily grown in almost any soil. The flowers, which are pure white, are but sparingly produced; but it is the spines, rather than the flowers, which constitute the chief beauty of this species. Stapelias are a kind of Cactus which may be easily grown. They are succulent, leafless plants, the branches of which are generally four-sided, toothed, and covered over with dark tubercles, which give the plants a grotesque appearance. Their singular and often beautiful flowers, which spring from uncertain points of the stems, exhibit a variety of colours, forming exquisitely marked or dotted patterns; and, notwithstanding the repulsive carrion-like odour which almost all the varieties possess, they are extensively cultivated because of their beauty. In addition to the above there are a great many other types of Cacti which are well worth growing, and a visit to Kew Gardens would offer a good opportunity for selection.

Phlox Drummondi splendens grandiflora.—This fine Phlox is well worth the attention of all who admire lovely flowers in windows. In pots or in the open ground it is equally effective, but I specially recommend it as a decorative pot-plant, as from the time when it begins to flower in the middle of June until the end of October it is never out of bloom. Its flowers are perfect in form and of an intense, rich, crimson-red hue, with a prominent white eye; the habit of the plant is robust and branching, and it is admirably adapted for cutting from without injury. Seed of it should be sown in pans in a cool house or frame early in April, and when large enough the young plants should be pricked out into other pans or boxes until sufficiently strong to be transferred, with a ball of soil attached to them, into pots. Four good plants are enough for a 6-in. pot, which they will fill thoroughly. Heat should be avoided as much as possible, but they like plenty of light and air.—A.

Petunias.—These make excellent window plants and are very showy, especially the flaked varieties, both single and double. To have them stocky and short-jointed they should be grown out-of-doors, fully exposed to the sun, and be stopped frequently, to induce them to break back freely and form bushy plants. When grown under glass the stems become drawn, which they likewise do in the greenhouse while producing their blooms. To obviate this as much as possible they should be placed in light, airy positions, where they only get a small amount of shade, if any at all. By cutting back any that have become straggling and drawn, and replacing them out in the open air, they soon break again, and flower with great freedom, so that a constant supply may be kept up by growing a few plants and treating them in this way. While out-of-doors the pots should be plunged, so as to prevent the sun from drying the roots.

Wild Flowers for Table Decoration.—Our native flowers and Grasses make extremely pretty table decorations, and during the spring, summer, and autumn months we frequently employ plateaux with an undulating surface covered with green wood Mosses, which form an effective and natural groundwork for wild flowers. Some of the rough Sedge-like Grasses, either taken up with roots or tied in bunches, are then introduced, and whatever kinds of wild flowers are in season are associated with them in irregular groups. Amongst these are the large Horse Daisies of our meadows, the Primroses and Bluebells of our woodlands, the aquatic plants that garnish our streams; and one plant, the Wild Carrot, that in Suffolk grows freely on dry banks and waste places, is so extremely pretty with its large flat heads of the most delicate little flowers, and looks so light and pretty, that I find it well worth cultivating, as I have not observed it growing wild in this part of Kent. Last season I sowed some seeds of this plant in good garden soil; and the size and quantity of bloom which they produced would convince anyone that even common native plants are capable of responding to liberal culture and producing better results than ever they do in a state of nature. And, to show how little our native plants are known and appreciated, I may mention that although many visitors well versed in exotic plants admired the light aërial beauty of this native flower, it was unanimously set down as a new and rare plant until seen growing accompanied with its well-known foliage, when it was at once recognised.—J. G.

Character in Gardens.—Were each to consult his own taste in the garden, instead of imitating his neighbour, every garden, large or small, would assume a character of its own. This would give variety and the sense of novelty or individuality to each garden, which could hardly fail to enhance the pleasure to be had from it. The garden is the very place in which to ride a hobby. It is much safer to do so than in any other occupation; for horticultural hobbies are always innocent, harmless, and, relatively to others, cheap. One lady, for instance, delights in Lilies—let her garden, therefore, be mainly a garden of Lilies. Another cares for nothing but Roses—what more charming than a garden of Roses! Another rejoices in spring flowers above all others—let hers be a spring garden. And so with all other plants, trees, shrubs, and flowers. Each man and woman's garden should mirror forth, as it were, the individual's taste. By amateurs selecting to grow most of those they like, room enough would be found to do their favourites justice.—T. F.

Dwarf Cactus (Echinopsis Pentlandi flammea).

Making Asphalte Walks.—A land agent at Warminster makes these as follows:—Living within a reasonable distance of the Cranmore Quarries, I obtain from them the mixture known as asphalte, viz.—gravel or stone chips mixed by machinery with tar to a certain consistency, which is then laid by two men upon a properly prepared bed of stone; the asphalte is separated into two qualities, the rougher and the finer, and laid in two courses to the depth of 1½ in. to 2 in.; this is sprinkled with sand and compressed with a heavy roller. Total cost in our neighbourhood varies from 1s. to 1s. 6d. per yard.—*Journal of Forestry.*

The Cottager's Hotbed Light.—Make a slight frame of 2 in. or 3 in. wide, to the size of a box, and tie across it strings, dividing it into squares of about 15 in.; paste together sheets of cartridge paper or newspaper sufficient to cover the whole, then paste and afterwards tack this to the outside of the light frame, letting it rest upon the strings. When perfectly dry take a brush or sponge and saturate the paper with linseed oil, which, when dry, will afford a congenial light to Cucumbers, or even Melons, retain the heat of the bed, draw the sun, and yet throw off the rays, and resist the weather for at least one season. Cucumbers grown under such a light have carried the first prize for flavour at horticultural shows.—A

THE SHRUBBERY.

Mock Oranges.—Syringas, or Mock Oranges, rank among the most effective and beautiful of all perfectly hardy and deciduous-leaved flowering shrubs. All of them have white or cream-coloured highly-fragrant flowers, and they are all very similar in foliage; hence, a selection of three or four species or varieties is sufficient for all purposes, except where the object is to form a collection. The principal thing to observe in selecting varieties for general planting in mixed shrubberies is their season of flowering. For instance, at the end of June the earlier-flowering ones are over, and the latter ones just coming into bloom. The earliest is Philadelphus coronarius, which, as a rule, begins to flower about the middle of May. For gardening purposes it is one of the species that we should recommend, because it is the first in bloom. The flowers, though much larger than those of the Orange, have a general resemblance to them, and they are also very odoriferous, without possessing the delicate perfume of the Orange blossom; indeed, their odour is too powerful for them to be employed extensively in bouquets, though agreeable to most people in the open air. There is a double-flowered variety which, in our opinion, is not superior, if even equal, to the common single kind. To alternate with P. coronarius, a pretty and very distinct species or variety, P. Satsumi, sometimes called P. chinensis, may be selected. It flowers almost as early and quite as profusely as P. coronarius, and it is likewise sweet-scented. Another fine form is P. tomentosus. It comes into bloom early in June, and bushes of it were literally covered with clusters of large flowers about a fortnight ago in the neighbourhood of London. P. grandiflorus is a tall-growing shrub, from 8 ft. to 12 ft. high, with irregularly-toothed leaves and fragrant flowers, nearly double the size of those of P. coronarius, and, as already mentioned, it does not begin flowering until the latter is nearly or quite over. These shrubs succeed in almost any soil and situation, but they appear to bloom most abundantly on a poor light soil. They are also exceedingly ornamental, particularly the early-flowering ones for a wall, sunny aspect, trellis, or arbour. Where only a small number is required, P. coronarius, P. Satsumi, and P. grandiflorus may be selected. All the varieties bearing the names included under P. grandiflorus are good. The Mock Oranges are not very rapid coarse-growing shrubs, and may easily be kept within reasonable compass by the judicious use of the pruning knife. But care should be exercised in the use of it, whether for the purpose of giving them a comely shape or reducing their size. The main branches of a bush may be cut away to the base or shortened; and it should be remembered, when pruning wall or trellis plants, that it is the short lateral branchlets which bear the flowers. Mock Oranges are grown largely in glasshouses by some florists for supplying cut flowers in early spring.

Double Crimson Thorn.—I noted some young trees of this Thorn in full flower at Tottenham a month ago, and could not but admire their beauty. It so happened that I passed the trees as the sun was declining in the west, and the bloom being lit up with softened mellow light the colour was charming. The double kind has, under any condition of light, much the deepest colour of all the Thorns, and as regards depth of hue is almost unrivalled amongst hardy flowering trees. It should therefore be universally planted, especially in villa gardens of moderate dimensions.—D.

The Mezereon (Daphne Mezereum).—This is unquestionably the earliest-flowering shrub we possess, and yet it is much neglected and but seldom met with in good condition in modern gardens, although in point of beauty and habit there is nothing left to wish for. Being of moderate growth, its best position is alone or on the turf, where its blossoms in early spring are admired by every one.

ROSES.

Pruning Climbing Roses.—The climbing varieties of Tea and Noisette Roses need but little pruning if they are required to cover a house or to furnish large quantities of cut flowers, as strong growth, and the laterals from this growth, are most productive of blooms. The lateral growths should be pruned back to the stem as soon as the flowers are cut; fresh buds will then be sent out from the same stems, and liquid manure should then be applied to assist the plants in providing nourishment to the buds, which thus produce finer flowers. It is not to be supposed that these Noisettes or strong-growing varieties will remain well furnished if they are not thinned out at the proper time. If a plant is required to furnish a greenhouse or wall, the young shoots must be encouraged, and a few of the weaker shoots thinned out, and then by training the growth horizontally instead of perpendicularly, as in most cases is the practice, it will be found that the laterals will break more evenly and the plants will not be so bare at the base. I have found that, by reversing the direction in which the strong shoots are growing before they break into flower, buds that have been quite dormant will be formed. If a plant of Maréchal Niel is required to cover a conservatory, it is advisable to carry one or two strong growths as high as the spring of the roof, and then direct the points horizontally, right and left. The shoots that spring from these may be carried, at equal distances apart, to the apex of the roof. If the shoots are carried at once perpendicularly, and without check, to the ridge of the house, they are sure to be very bare at the bottom, as the strong varieties of Teas and Noisettes do not break so freely as the Grape Vine does when treated on the same principle. If the above advice be carefully attended to, the plants thinned out, and the flower shoots pruned back, it will be found, with watering and keeping the plants free from blight, that the Maréchal Niel, Devoniensis, and Lamarque Roses will flower twice in the season.—G.

Layering Roses.—Roses are mostly layered either in the autumn or early spring months. Perhaps November is the best month. Some varieties root readily if the shoots be only pegged down firmly to the ground and covered over with 1 in. or 2 in. of earth. Others, and the more slow-rooting kinds, have a tongue slit or opening made at the base of the bud where roots are expected to be produced. This opening or cut may be made under or over the shoot to be layered. Either way, in covering, a small stone or wedge should be placed in the cut so as to keep it partly open. Roots are then formed and sent forth from the end of the cut portion just as if it were a cutting. The weaker side shoots are the easiest to bend down to the earth; they also root most freely, and consequently form the best layers. The layering of Roses should not be attempted later than March. Many, however, prefer layering the half-ripened wood in June and July. If branches with later shoots be layered at that season, most of the side shoots may be made to root and form independent plants before winter. There is thus the gain of a season; for layers of ripened wood formed in the autumn or spring will not be sufficiently rooted to form independent plants till a year after, whereas summer layers form plants in a few months. There is yet another simple mode of layering dwarf Roses. At the winter pruning bend down and bury the heads of the side branches a few inches in the earth. Most of these will speedily form masses of roots, and send up strong shoots when the growing season comes round; and the plants from such layers can, of course, be detached from the parent stools in the autumn.—T. F.

Cats in Gardens.—As there has lately been a little correspondence on this, and on "the law on the subject," in Gardening Illustrated, I may inform "W. H." and "Major" that on looking over an old number of the *Exeter Gazette* (June, 1878), I find the case of a gentleman heavily fined at Brixham for shooting a cat while destroying one of his fowls. As a fowl is possibly of more value than a few seeds scratched up or displaced, "W. H." and "Major" may also some day find such a stop to their amusement of destroying what may be their neighbours' pet animals, even though they have sometimes a habit of running beyond their owners' grounds.—Justicia.

Paraffin as an Insecticide.—We have on the roof of the stove here a large plant of Stephanotis which was infested with mealy bug, and I syringed it with a mixture of one wineglassful of paraffin to four gallons of cold water, keeping the same well mixed by driving every alternate syringeful back into the pail again. The bug was destroyed and not a leaf was injured. Large plants of Gardenias were treated in a similar manner, and with equally good results.—W. T.

Draining Pots.—I am tempted to submit for the consideration of more experienced gardeners than myself a plan which I have never once found to fail during the last three years, and which, moreover, is very expeditious and easy. It is to put one crock over the hole and then an inch, more or less, of Cocoa-nut fibre refuse. You can no more choke this than you could a sponge.—H.

Elephant Cactus (Mammillaria elephantidens).

VEGETABLES.

CROPPING FOR WINTER.

From May till September is a period of the year of which possessors of gardens should make good use, or they will be short of many things which are needed most between Christmas and June.

Broccoli.—This is one of the most important of winter crops. The summer Cauliflower does well if it lasts till Christmas, which in tolerably mild autumns and early winters it sometimes does with the aid of the Walcheren—the hardiest of its class—Grange's Autumn Broccoli, and Veitch's Giant, and a little attention in the way of protection; but it is most commonly over before November is out, and then we look for the Broccoli coming in to carry on the supply till next midsummer. Notwithstanding successional sowings and planting, however, Broccoli cannot always be got to come in so regularly at any time as to prevent blanks occurring in the supply: everything depends on the weather after all. If the temperature keep above the growing point the plants will grow apace, and keep dropping in slowly; but if the thermometer drop sensibly below 40° and remains so, the supply will doubtless come to a standstill. We cannot say that sowing at any period between February and the middle of April in a late district ever gave us heads either earlier or later in the winter, for we have paid attention to the matter often. The wisest course is to select a goodly number of varieties, which should comprise the best and hardiest only, from the very earliest to the latest. The next point is to sow thinly not later than the end of March, and to plant out from the middle of May till the end of June in late situations, and till the end of July in more favourable districts, putting the earliest varieties out first. This is allowing a pretty wide margin as to time; but we may state that though we have had tolerable heads from plants put out in August, and many cannot get the work of planting done before then, still we always contrive to get all finished by the end of June, and all the varieties are planted at the same time. If the weather be dry at planting time, and for a while after, time is lost, for the plants hang fire so long before they begin to grow. Much, however, depends on planting. If the plants be got up carefully, with long top roots, and if these be let straight down into a good deep hole made with the dibber, and one thorough watering given at the finish, there is not much to fear. In warm growing seasons we have had young Broccoli plants with roots 12 in. or 18 in. long before they could be attended to, and they were planted thus:—A man with a broom-handle went along and made the holes deeper and wider than required, and another came behind and put them in and filled up. These plants always did well, and made giants before winter. Trenching, deep digging, and manuring of the ground is almost executed if it has been occupied by any of the Brassica tribe just before. When Broccoli begins to head and come in in a regular way, the supply is often greater than the demand. When this is the case, the heads should be cut with a good quantity of leaves to them and set in sand in a cool, dark shed, or behind a north wall, with a mat spread over them, or they may be put into the ice-house. Here we have kept them for a month, but after ten days or thereabouts they begin to taste when cooked.

Brussels Sprouts.—If the ground be clear, these cannot be planted out too soon. The longer the period of growth they have, the taller they will be and the more sprouts they will bear. If very large Sprouts are desired, then high culture, as for Broccoli, will be necessary, and the kinds which produce the largest Sprouts must be grown, such as the Dalmeny and Dalkeith; but with high-class cooks, and those who like to produce artistic dishes, the small hard Sprouts are preferred, as being most useful, and because they cook whole and green; large and loose ones, divested of their outside blades, are faulty in these respects. A distance of 2 ft. or 2½ ft. is enough between the plants when put out in good time, but the shorter the season of the growth before them the thicker they should be planted.

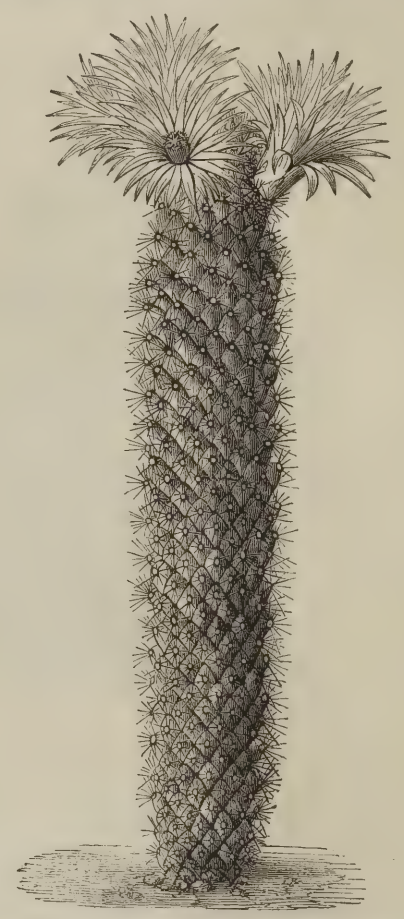
Savoys.—This excellent winter Green is preferred to Cabbage, and is much esteemed in some places. Only after it has received a touch of frost is the Savoy considered in season, and it is good to use it in early winter while it lasts, for the heads suffer sooner from frost than either the Brussels Sprout or the Cabbage. For bulk of crop, the old and somewhat coarse Drumhead is the best, but for better garden crops the Dwarf Green and Early Ulm are among the best, being early hearters, and tender and good. These kinds may be planted almost as closely together as Dwarf York Cabbage, and they will heart, though put out as late as the beginning or middle of August even in the north, but a month earlier enables them to produce larger and firmer heads. The Savoy likes liberal treatment like the rest of its tribe.

Cabbages.—As to these, a good breadth planted late in autumn or early in spring should—between the first cut heads and the hearted sprouts which they bear after—carry the supply well through the summer and winter; but, as a precaution, a sowing should be made in July or August of any of the early dwarf kinds, and also of the early Enfield, to succeed the first lot. It is well to have a good supply of tender Cabbage in the winter months.

Curled Greens.—These are not the least important of our winter crops. They are run upon when others fail, and are always in demand from the beginning of winter till near the end of June. "Be aye stickin' in a tree" was Dumbiedyke's advice to his son; and we would say, "be always putting in Greens as long as you have any spare ground to fill." There are always plenty of families ill-provided with vegetables during winter who are thankful for a "boiling" if they can get them, and it is wrong to waste them, as is often done, simply through letting them run to seed. It is not necessary to manure highly for Greens, but the ground should not be too poor. Still, we have planted the same ground for years in summer with Greens, giving them only the leavings of the manure heap, and have never had reason to complain of an ill crop. It is seldom that the planting of them can be done before August, and we continue to put them in till September, as Potatoes and such like crops are cleared away. It may just be mentioned that there is no vegetable of the kind of which more is sold, and sold profitably, than Greens, especially in the provincial towns and their neighbourhoods. Hawkers carry them far and wide for sale in the populous districts in the north of England.

Winter Turnips.—A good supply of these is a great desideratum during the winter and spring months. It is difficult to gauge the exact time to sow, but, making allowance for difference of climate, the main winter crop should be got in between June 20 and July 20, sowing earliest, of course, in late districts, and later in the south and in early localities. Two sowings, however, are best, allowing a fortnight between them, and then a good standing winter crop is almost certain. Winter Turnips should not be above half grown when winter overtakes them, as they then stand frost and alternations of the weather better. Mature, full-sized roots are the first to give way. Moderately rich ground and a deep litter should be afforded them; and when the plants are past all danger from fly, they should be thinned out to 2 ft. apart each way if sown broadcast, and if in drills, which is the best plan, the rows should be that distance asunder. Turnips which are thick on the ground never stand the winter well. Some people sow a later crop between the first and last weeks of August to succeed the first, but such a crop should not be trusted to. They may form usable little bulbs in spring, but the chances are that they will never come to anything, and run to seed the first thing when growth commences. Behind a north wall is a good situation for a winter crop of Turnips, as they are always in the shade during the short days, and, not being so often frozen and thawed, they last better. Chirk Castle is by far the best variety for winter, being very hardy, white-fleshed, and good.

Tender Cucumbers.—It is hardly too much to say that in nine cases out of ten Cucumbers are not cut until they are a long way past their best. Two-thirds grown is about the best size for Cucumbers. Beyond that stage they deteriorate. It is somewhat surprising that they should be allowed to do so; for Cucumbers are invariably sold singly, by the brace, or by number; none, unless pickling ones, are sold by pound, stone, bushel, or ton. Neither is there any loss of weight by cutting Cucumbers early. On the contrary, there is a great gain. The earlier the fruit is cut, the more will be produced and the longer the plants continue bearing. There is nothing like early cutting for perpetual fertility. Each fruit removed at one-half or three-quarter size is succeeded by two or three more. A second fruit will almost be fit to cut before the first would have been removed under ordinary circumstances. Early cutting also maintains the plants in the highest health and fullest strength. Of course, no one thinks of ripening Cucumbers, unless for seed. But there is much strain on the plants a long time before perfect maturity. By early cutting we almost hinder the seeds from being formed at all, and this also conserves the quality of the Cucumber, for it cannot have failed to attract notice that the finest-flavoured Cucumbers are those without seeds. Seed-bearing is fatal to tenderness, crispness, and sweetness. For this additional reason we would therefore advise the early cutting of Cucumbers. It is well, also, to pick off all the male blossoms as soon as they appear. This would effectually prevent seeds being formed. Cucumbers without seed are more uniform in size and more delicate in quality than those producing seed. It used to be thought that Cucumbers would not grow freely unless they were impregnated. This is quite a mistake. They swell equally well, and in fact are better for eating if all the male flowers be removed from the first. There is yet another plea for small Cucumbers—they can hardly be eaten too fresh. Cut and eat at once should be the rule. Almost the smallest household can eat up a small Cucumber at a meal or in



Erect Cactus (Mammillaria erecta); flowers yellow.

a day. A large one would last several days or perhaps a week. From the moment it is cut it begins to deteriorate, and by the time that it has been cut several days a Cucumber is hardly worth the eating, becoming stale, flaccid, or insipid.—D. T.

Strawberries and Peas.—I divide my garden into two portions; one I keep chiefly for Peas, with Strawberry borders; the other for roots and Beans, Potatoes, Carrots, Beet, &c. The Strawberries bear very well for five years, but some renew in three or four years. When I want to renew, I portion out a part of the ground (in which I used to sow late Potatoes as a rotation crop) and plant Strawberry runners. In the first spring I go over all the plants and root out the barren ones; and in the autumn I remove the bearing plants to the borders, and I have remarkably fine Strawberries, all bearing plants. Till I adopted this plan I found I had many barren plants in the borders. I also water the Strawberries by a shallow trench on each side, so that the roots get well watered; I likewise give one or two waterings of guano water—a tablespoonful to a gallon—when the plants begin to grow, and when in flower I generally tie up the fruit-stems to a stick, so as to get the sun, and use old tan and Cocoa-nut fibre. I tried Grass mowings, but the Grass heated and destroyed the fruit. I may mention also that one year I dug up some four-year-old plants, and, instead of throwing them away, divided the roots and planted in some spare new ground, and I never saw a finer crop of Strawberries. I dug them up after bearing, much to the disappointment of my gardener, who wished me to try another year; but I wanted the ground for Peas. I find the best plan for sowing Peas is to make trenches 6 in. below the surface, even for early Peas; they are nearer moisture, and can be easily watered, and are protected from cutting winds, and they can be earthed up if necessary. For succession I find sowing on March 1 best with Alpha, Wonderful, and other Peas, according to height (2½ ft. to 6 ft.), G. F. Wilson, James's Prolific, and I find I have Peas every day. Of course, a second or third sowing can be made much on the same principle; it enables you to have a variety. You might sow only one kind, say Wonderful, and as one crop comes up put in another; but this is not so good, as I often found Peas sown a month later than others came in almost at the same time.—OLD INDIAN.

FRUIT.

SUMMER PRUNING FRUIT TREES.

Pinching Trained Trees—Pears and Apples.

THE object of pinching off the tips of shoots is to diminish their vigour; only those of a moderate strength can be converted into fruit twigs. As soon as the shoots of the year are about 6 in. long and have made six or seven well-developed leaves, not counting the rosette of small leaves at the base of the shoot, pinch off the extreme point of the shoot beyond the sixth or seventh leaf. If pinched shorter—say at three or four leaves—and there should happen to be no latent buds at the axis of the lower leaves of the shoot, which is a characteristic of certain Pear trees, such as the Beurré Diel, the Jargonelle, and the Doyennés, the shoot would be destroyed and a void left in its place, at least for a time; while, should there be buds at the axis of the lower leaves, pinching so short would be likely to develop these buds into so many anticipated shoots—the very buds which we desire to transform into fruit-buds—it being our object to obtain the fruit as close to the main branch as possible. Therefore, we say pinch the shoots when about 6 in. long, leaving from six to seven well-developed leaves. Shoots so treated will frequently produce an anticipated shoot from the axis of one of its last leaves. This shoot must be treated in much the same manner as the shoot from which it springs, pinching off its extreme point when about 4 in. long.

When more than one anticipated shoot is developed the primary shoot is shortened, so as only to leave one anticipated shoot upon it at any time. If any of the shoots may have escaped observation until they were more than 8 in. long, it will be too late to pinch. In this case cut the shoot off close to its base, leaving a small portion of the base about ⅛ in. long. Two shoots should presently be developed from latent eyes close to this base; remove the stronger and retain the weaker; it is likely to be well constituted for being formed into a fruit-bearing twig. It is important that the end of the mother branch from which all these productions spring should be kept growing. Never pinch the shoot which forms the continuation or prolongation of a branch; on the contrary, it must be favoured, and for this purpose, if necessary, turned upwards, to be cut down to one bud at winter pruning; if the branch has reached its determined limit, the same operation to be repeated yearly.

All strong shoots growing vertically from the upper surface of a branch trained horizontally are removed, as are the shoots in a corresponding position on a branch trained obliquely; they are cut back close to their bases, and from the latent eyes at the base are obtained weaker shoots, or shoots growing in a more lateral direction Strong shoots must be pinched longer than weak ones; also shoots on some varieties of Pears and Apples require to be left longer than those on others. According to this method trees will require continued attention all the

summer, but principally during the months of May and June. OMBU.

Air Roots on Vines.—What are known as air-roots on Vines are the root-like growths which push from the wood above ground. They generally appear in the greatest quantity near the spurs, and less frequently upon the clean wood or stem. They usually number from two to a dozen, or even more, sometimes coming in bunches, and sometimes in rows. They resemble earth roots in some respects, but they do not often divide into rootlets; they begin to grow with the rise of the sap, and continue growing until it descends again. All varieties of Vines are subject to them, and it is often said they do no harm, which may perhaps be correct so long as they are few and small; but there is reason to believe that where they occur to any great extent they at all events do no good. I was lately requested by an amateur to come and see his Vines, as he could not understand why he had no Grapes on them this season. I ascertained that for some years air roots had been annually increasing and the crops diminishing. This year they hang down over 1 ft. in length, and there is not a vestige of fruit on one of the Vines. There can be little doubt that these air roots have, in a great measure, brought this about, and if their influence in this case has been antagonistic to fertility, it may be assumed that they will always produce effects which will be more or less injurious in proportion to the frequency of their occurrence, for the nourishment which supports these roots, or other superfluous growths, is that which should properly go towards the formation of fruit-bearing wood. Air roots should, therefore, be regarded and treated as any other Vine disease. They are the production of an imperfect root action in the first place, and a damp atmosphere encourages their growth afterwards. Young Vines are not so liable to become affected as those that are middle-aged or old. Vines on which the berries shank generally form air roots; but they also occur on those that are quite free from this disease. Their growth is often very vigorous when the Vines are first started, especially if they are kept close; afterwards, when more air is admitted, their points get starved, and further growth ceases; where this is the case, they do not do so much harm as when they continue growing throughout the season; and this they always do if not checked in time. Cutting, or rubbing them off, when they are growing vigorously, does no good. The points do not start into growth when once broken; but a second batch is invariably pushed from the base of the first. It is as well to let those that do appear remain and grow until the end of the season, when they may be cut away with a sharp knife while pruning. Vines with their roots in borders which are damp, or in which all the fibre of the soil has decayed, generally produce plenty of air roots, as a close adhesive soil is not by any means conducive to the healthy development of any Vine. When air roots appear in quantity, no time should be allowed to pass without making an examination of the border. Fresh drainage, where necessary, must be resorted to; and a quantity of fibrous turf and lime rubbish is of service in sweetening the soil. After the border had been thus renewed, the atmosphere of the Vinery should be kept dry during the early growth of the Vines.—J. M.

Mulching Outdoor Strawberries.—Although this is generally done to keep the fruit clean, it in reality answers an even more important purpose, viz., that of keeping the ground moist and cool; and, with this twofold end in view, a good mulching of fresh stable litter should be put on not later than March, before the young foliage gets far advanced in growth. If roughly shaken over the beds, and regulated by hand round the crowns, it soon settles down, and the spring showers wash it quite clean before the fruit is ripe. If left until the Strawberries are in bloom, it is much more troublesome to apply, and in a dry season like the present the retention of moisture in the soil by retarding evaporation will go far to carry the crop on to a finish; and any supplies of liquid manure given during the early stages of growth will prove much more beneficial than in the case of exposed beds. Mulching is an operation which a few wet summers bring into disrepute, but in dry weather it has to be resorted to. For bush fruits I find it to be a most serviceable help; also for many kinds of vegetables, and for wall trees in particular; but in all these cases it is best applied in good time, before the soil has become dry. If not already applied, a good soaking of water in addition to the mulching will be found of great service to the trees; as, in addition to the protracted drought we have had, there has been an almost continuous arid wind that extracts moisture very rapidly if not counteracted by external coverings.—J. G. L.

Thinning Pears.—The only way to ensure full-sized specimens is to thin out early in the summer. With Apples, Pears, and Peaches, this thinning can be done in July, the smallest ones being pulled off, and the more advanced and perfect left. In orchard management I have often plucked off half of the Pears on the trees, literally covering the ground with partly-grown fruit. When gathering time came, what were left on would measure and weigh quite as much as if none were taken off, while their market value would be two-fold at least; I have known of cases when it would be four times as much, with no injury to the trees. There are some kinds of Pears that will be more responsive to thinning than others, and will pay liberally for the labour. Kinds that set thickly, like William, Louise Bonne of Jersey, Duchesse d'Angoulême, Belle Lucrative, and Doyenné Boussock, should always be thinned when the fruit is the size of a Walnut. When two Pears come close together one may be pulled off, and the remaining one, at the end of the season, will equal the two in size and be greatly superior in quality. High culture and careful thinning of Apples and Pears are the only sure roads to success.—P. D.

Melons Splitting.—There is no doubt that the splitting of Melons just before ripening proceeds from different causes. In a Melon pit here I used to have many fruit split, but at last I found out one of the causes of the evil, from which I have since been nearly free. When the fruits hanging from the trellis began to get heavy they were supported by a thin, square bit of wood, suspended by wires fixed at each corner to the trellis. Owing to the fruits resting on their ends on this piece of timber when the plants were syringed, the water lodged between the board and the fruit, and caused them to split just at the end. Now the syringing is given over before the ripening process takes place, and the fruits, being placed on their sides on the boards, never split as they used to do. —W. T.

Cereus candicans; flowers white.

HERBACEOUS PÆONIES.

FOR nearly a month our garden borders have been enlivened with the beautiful and showy blooms of the herbaceous Pæony. Planted among Conifers, flowering shrubs, and ornamental trees, their gay-coloured flowers produce a charming effect. On our grounds we have a border, 200 ft. in length and 15 ft. in width, which contains a choice collection of ornamental trees, conifers, shrubs, Roses, Pæonies, and hardy border plants. The tall-growing trees and evergreens form the background; the shrubs and trees of medium size come next; with the Pæonies, Roses, and border plants in the foreground. The assortment of Pæonies when in flower is undoubtedly the most interesting feature of the collection.

In our nursery grounds a large circular bed about 20 ft. in diameter, planted with the most showy and distinct varieties, has, during these beautiful sunny days, attracted great attention. It is surprising that so noble a flower, almost rivalling the Rose in brilliancy of colour and perfection of bloom and the Rhododendron in stately growth, should be so neglected. Amateurs seem to have entirely lost sight of the many improved varieties introduced within the last few years, and our finest gardens, perfect in other respects, are singularly deficient in specimens of the newer kinds. In the hope of popularising to some extent this valuable class of plants, I will briefly refer to their many desirable characteristics of growth and flower, and at the same time furnish the names of a few choice sorts.

The first point in their favour is hardiness. It may be truly said of them that they are "hardy as an Oak." In the severest climates the plants require no other protection than that which they afford themselves. Then their vigorous habit and healthy growth, freedom from all diseases and insects, are important arguments in favour of their cultivation. Growers of Roses know well that their flowers are obtained by great vigilance and care. Not so with Pæonies, with which when once planted all is done. Each succeeding year adds to their size and beauty. The foliage is rich and glossy and of a beautiful deep-green colour, thus rendering the plants very ornamental even when out of flower.

The newer varieties produce very large, handsome, regularly-formed cupped blooms, resembling large Roses. The Pæony may be planted either singly on the lawn or in borders. Where the lawn is extensive a large bed makes a grand show, almost equal to a bed of Rhododendrons. The following are six of the best and most distinct kinds:—Modeste, deep rose, very large, cupped like a Rose; Delachii, dark purplish-crimson, the best dark variety; Ambroise Verschaffelt, purplish-crimson, very full, fragrant;

Papilionaceæ, white, superb large flower; Humei, deep rose with purple shade, very full and double, one of the latest in bloom; Whittleji, white centre, slightly yellowish, fragrant. For a dozen add the following:—Chas. Verdier, lilac-rose, of perfect form, cupped; Monsieur Boucharlat, bright rosy-lilac, large, full, fragrant, and very late; Dr. Bretonneau, rosy-violet, large and of fine shape; fulgida, crimson, profuse flowering; delicatissima, flesh colour, delicate and beautiful; Festiva, pure white, with a few marks of carmine in the centre. Early-flowering varieties—tenuifolia, single dark crimson, leaves beautifully cut; rosea, double crimson at first, changing to rose, beautiful; and pulcherrima plena, crimson, with purple shade. —W. C. BARRY, in *Brief Essays*.

Climbers.—Roses, Clematis, Honeysuckles, and other plants of a similar character covering walls, will, as they make growth, require nailing, tying to wires, or securing in some way; but do not allow the shoots to grow too long before this is done, or they are certain to get broken or chafed by the wind, and it is the more necessary to attend well to this in the case of any that have not yet covered their allotted space. It frequently happens that plants intended to cover walls, however desirable it is that the object should be accomplished with as little delay as possible, do not receive sufficient water in dry summer weather; even when enough rain falls to moisten the soil sufficiently where it is open, it does not always reach the roots of plants so situated, especially where the walls are high. In such cases good soakings of water should be given when it is dry. The blooming of Roses that cover large spaces on walls is often of very short duration, on account of the deficiency of moisture at the roots, and not only is the flowering affected, but the foliage is scanty, and becomes a prey to aphides and red spider; the use of the garden-engine or syringe is here indispensable, as the leaves, from their position, receive little benefit from being washed with the rains. As the first flowers of the Hybrid Perpetual section are over they should at once be removed, or they will seriously interfere with the later blooming. Keep the foliage clean and healthy by repeated use of the syringe; this will greatly assist them in producing flowers through the season.

Perennial Larkspurs.—When in suitable soil these throw up strong shoots and splendid spikes of flowers, which are remarkably showy during June, July, August, and September. The tallest are well adapted for forming back lines to mixed borders, while the dwarfer growing sorts come to the front, and, by judiciously arranging the colours, a pleasing effect may thus be obtained. Beds of Larkspurs are also very effective, the tall growing sorts being in the middle and the dwarfer ones on the outside. They vary also in time of flowering, some being early, others late, and so a succession may be had through a considerable period. In height, Larkspurs vary from 1 ft. to 6 ft., and the colours include bright scarlet, as in Delphinium nudicaule, pure white, pale lavender, and every shade of blue, from clear azure to deep indigo and almost black. Some have pure white, others brown and black centres. The flowers vary considerably in form and size, and the varieties include single, semi-double, and perfectly double imbricated flowers, and the flower spikes vary in length from 1 ft. to 3 ft. All are perfectly hardy, and may be cultivated in any ordinary garden soil. A deep good loam suits the Larkspur well, especially if assisted by occasional dressings of manure and leaf soil, which should be placed on the beds as a top-dressing early in spring, and forked in during April. If I were preparing a piece of ground for a plantation of Larkspurs, I should deeply trench and well pulverise it, giving a good dressing of manure as the work proceeded; and, previous to planting, a good dressing of leaf-mould, forked in and mixed with the top spit, would be of service. In the case of soils that are tenacious and wet, thorough drainage must be resorted to. Depth of soil is of great importance in the culture of the majority of herbaceous plants. If shallow, and lying on a hard sub-soil, their bloom will be comparatively poor and short-lived, especially in dry seasons and localities. Some recommend Larkspurs to be lifted annually; but if a top-dressing be supplied in spring, moving once in three or four years will be enough. The plants may be divided at lifting time in order to increase the stock, but no roots should be divided till they are strong. If a few side shoots be taken away in the autumn, and potted in some fine rich soil, and kept in a cold frame during winter, they will root readily; or if taken off early in spring and put into a slight bottom-heat, the cuttings soon make roots, and grow into plants that flower at midsummer or soon after. These Larkspurs supply hues of blue not found in other plants, and when well grown have a fine effect.—O. U.

Violets for Winter Blooming.—We have at present a row of Czar Violet in patches at the bottom of a south wall. These flower freely and long in spring and early summer. The runners are chopped off with a spade several times during the season to keep the shoots vigorous, which get a good size in a single season, and about November and onwards we take up a number of patches at a time, pot them in 8-in. pots, and put them into the Vineries or anywhere convenient where there is a gentle heat. Thus treated, flowers quickly make their appearance, large and sweetly scented; and, though the plants do not continue to bloom for a very long time, we have plenty of them to fall back upon, and therefore introduce another batch.—S. W.

Hints on Pruning.—No subject is of greater importance to gardeners and those who are amateurs than that of pruning. I shall not accuse gardeners of ignorance, for to do so would be akin to pedantry; but I must say many of our gardens are wholly spoiled by the wholesale use of the lopping-knife and pruning-scissors. If there is a vice in the art of gardening, it is that of stumping all things, from a Pansy to a Pear tree. Half the fruit and flowers of our gardens are destroyed by that insatiable thirst for show; and in order to bring one Pear to extraordinary size—or a Gooseberry, for example—the whole crop is sacrificed on a tree. I do not believe in allowing trees or shrubs to run wild—far from it; but I ask, is modern gardening at all calculated to increase the produce of fruit trees? I say, no. My garden has been spoiled for years by the vicious system of over-pruning; and many of my trees are standing objects of such treatment. My advice, if it is at all of use, grounded as it is upon experience, is not to prune excessively; and above all things do not let the so-called professional gardeners spoil your fruit trees. They only want mild treatment; and if any of your readers will only look at old orchards, Nature, by lopping off branches, does the pruning herself, and supplies us with an abundant fruit harvest. If gardeners only exercised common sense, they would not spoil our gardens as they do now. Cottagers get three times as much produce as we, who habitually are compelled to employ professionals because we cannot do the work ourselves, and cannot always superintend. My remarks must not be construed as those of outspoken censure, but plainly as a kind of admonition, given in a friendly spirit, and which should be accepted as kindly advice.—HENRY BROWN, *Northallerton*.

How to keep Birds off Small Fruits.—Small and cheap fireworks—squibs and, better still, crackers—have been found very efficacious aids in my garden in the season of small fruits. Though we use nets freely there is much that cannot be so guarded; and as birds have always reared their young and ceased singing by the time Strawberries, Currants, and Raspberries ripen, we drive them away by crackers and squibs, discharged early in the morning at intervals, and again in the afternoon. The birds betake themselves to the Turnip and Potato fields to feed upon the slugs there, as they were allowed to do in the garden previously, which is consequently never injured by those slimy visitants. It is hardly necessary to say that sparrows may be scared just as easily by squibs and crackers, which lie smouldering and emitting an alarming scent of gunpowder long after the explosions have ceased.—R. C. E.

Destroying Gooseberry Caterpillars.—I have adopted the following method of getting rid of this pest for twenty years, and never knew it to fail. To half-a-pound of white hellebore powder add about twelve quarts of water, and mix them well. Take the syringe, with the jet end on, draw it full of the water and powder mixed, and force it out into the bottom of the can, making the water and powder boil up, as it were; again draw the syringe full whilst the liquid is in motion, and, with your finger on the end of the jet, thoroughly damp over every part of the tree affected. If the pest has made headway, a second application is sometimes necessary. It is best to apply the mixture on a quiet, still night. About a week after, damp all the trees with clean water should the weather be dry. Let them remain for half an hour or so, to loosen the powder on the leaves and fruit, and then give them a brisk syringing, which will leave them quite free from both caterpillars and powder.—J. S.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

June 28.—Sowing Canadian Wonder and Long-podded Negro French Beans; pricking off seedling Violas; planting out Ten-week Stocks and Asters; thinning out Spinach and Turnips; stopping and nailing in shoots of Tomatoes; taking up early Ash-leaf Kidney Potatoes and spreading them out in the sun to ripen well for early crops next season; mulching Morello Cherries and watering them; potting Thyrsacanthus, Poinsettias, double Wallflowers, and Amarantus; planting verandah boxes with Stocks; putting out main crop of Celery, Chilies, and Chervil; putting in cuttings of Poinsettias, staking Carnations, and removing superfluous shoots from espalier Pear trees; earthing up Brussels Sprouts.

June 29.—Sowing Early Horn Carrots and red and white Turnip Radishes; potting off herbaceous Calceolarias, Primulas, and Cinerarias; mulching late Peas with rotten manure and well watering them; thinning out Chicory, Dandelion, Salsafy, and Scorzonera; planting out Lettuces and Endive; also Marjoram and Sweet Basil; watering all newly-planted Broccoli and Brussels Sprouts; taking nets off early Cherries and putting them over Currant bushes to protect them from birds; turning over gravel walks where covered with Moss, to give them a fresh appearance; potting Victoria Stocks, and putting winter Carnations into their flowering pots; sowing Campanula seeds, Parsley and Intermediate Stocks; planting May-sown Lettuce and Snow's White Broccoli; putting Heliotrope cuttings to make plants for winter flowering; digging land for late Peas and Broccoli; putting Amaryllis in sun to ripen their bulbs.

June 30.—Sowing All the Year Round, the Favourite, and Giant White Cos Lettuces; also Green-curled and Batavian Endive; potting first batch of Strawberries for forcing; planting out Celery and Cardoons; giving Asparagus beds a light dressing of salt; mulching and watering Peach trees on walls; staking Peas and getting them earthed up; thinning Early Horn Carrots; planting Autumn Giant Cauliflower and Savoys; taking up Hyacinth bulbs and drying and storing them; nailing in Peach, Plum and Pear tree shoots; thinning Turnips.

July 1.—Sowing Omega and Ne Plus Ultra Peas; potting on small plants of Dracænas and Pandanus Veitchi for table use; planting out Cauliflowers and late Broccoli; giving early Celery a little earthing, also Leeks; clearing off Cauliflower stumps, manuring the ground, and getting it dug up ready for other crops.

July 2.—Sowing Early Snowball and American Strap-leaf Turnips; planting out a four-light pit with Tender and True Cucumbers; sticking late-sown Scarlet Runner Beans; forking and Dutch-hoeing amongst all growing crops; salting walks to keep down weeds; putting Chrysanthemums into their flowering pots, and potting young Heliotropes and scarlet Pelargoniums; re-potting Canterbury Bells and Intermediate Stocks.

July 3.—Sowing late crop of Broad Beans; also Mignonette for autumn flowering; putting in cuttings of choice Pelargoniums; potting on Balsams; drawing drills for Turnips, and well watering them previous to sowing; renovating linings round all manure frames; nailing in leading shoots on Apricot and Plum trees; giving Peach trees in early house a good washing with soft soap, sulphur and Quassia-chip water, to keep down insects; potting Selaginellas for conservatory decoration, and putting young Vines into 10-in. pots; planting a border with Ten-week Stocks and Asters; looking over Gooseberry bushes and destroying caterpillars; putting all spring-flowering bulbs that are dried off into hampers and storing them away in a cool place; hoeing among Onions, Carrots, and Beetroot.

Hardy Flowers.

Carnations and Picotees.—It is necessary to devote careful attention to these just now, as any check to their growth would be fatal to the development of full-sized, well-marked flowers. Tree Carnations now making good growth must be shifted into larger pots as they require it. The largest plants may be permitted to flower in 8-in. pots, and smaller plants do well in 6-in. and 7-in. ones. What they require to grow in is good turfy loam, well enriched with rotten stable manure and crushed bones, and they must be well supplied with water at the roots all through the growing season. At present they succeed best out-of-doors; the pots should be placed on a hard bottom, in order to prevent worms from getting through. Never at any time use manure water; the only time when

this is useful is when the plants have become exhausted from flowering freely.

Pinks.—This is now the best time to put in pipings. The smallest growths strike root most freely, and if the weather is dull and showery at the time when they are taken off, they may be put in in a shady position quite in the open ground. It is rather more difficult to propagate the Pink in the south than in the north, and in dry sunny weather it is best to place the pipings in boxes, and to strike them on a very mild hotbed. They must be shaded from the sun until roots are formed.

Pansies.—It is a good plan to put in some cuttings now to form a late autumn bed. If it is intended to have good flowers for an exhibition or other purpose on a given date, pinch off all the flowers that are open or nearly so—indeed, even buds that are showing colour—about a fortnight before the date on which they are required. No flower degenerates more rapidly than Pansies, and the only way to maintain them in good condition is to occasionally denude them of flowers and apply surface-dressings to the beds.

Phloxes in Pots.—The utility of these for conservatory decoration has already been alluded to, and they must now be well attended to, in order to have them very strong at the time of flowering. The Phlox is a gross feeder, and absorbs an enormous quantity of rich stimulants, either in the way of surface-dressing or manure water, not too strong. Tie the growths to stout sticks as they advance, and place the plants where they can obtain plenty of light and air.

Asters and Stocks.—Successional plants of these may be planted out, and by putting in a later batch the bloom may be kept up further in the season. Asters, especially, are so useful for cutting, that it is desirable to have them as late as they can be had.

Gladioli.—If hot dry weather should set in immediately mulch the beds with rotten manure, and apply water freely if thought needful. It is also necessary to place sticks to the plants in the earliest stages of the spikes, as the broad leaves are much acted upon by gales of wind, and if the roots get loosened the plants soon fall over.

Tulips.—The roots of these ought to be lifted at once and stored in a dry place until planting time. Regular Tulip growers have drawers fitted with boxes, divided into compartments, into which each variety is placed and numbered. We simply lift the roots and clean them, placing each variety in a small flower-pot, which is stored in a dry loft, and thus managed they keep in good condition until planting time.

Ferns.

There is certainly no season of the year when Fern houses have a more beautiful appearance than at present, when the different tints of the young green fronds are in most cases developed. Everything possible should be done that will tend to preserve them in good condition. Unless these plants be free from mealy bug, scale, and thrips, it is impossible to keep them in a satisfactory state all through the year; the two former, from their glutinous excretions, to which the slightest dust adheres, soon causes the fronds to look black and dirty; and the thrips, though easier to kill, not only disfigure the fronds, but also cause them to die off prematurely. The fronds will not be in a state now to bear a strong enough application of any insecticide to kill scale and bug, and these should be sought for and removed by sponging. Tobacco water is the safest remedy for the thrips. Any plants in small pots or tubs, particularly of the Tree species, will be much assisted by frequent applications of manure water moderately strong. Where a large collection is planted out, it is necessary at this time of the year to see that the strong growers do not encroach upon the weaker ones; this can be effected by cutting the older fronds away freely, which will at once reduce the size of those that are to come. The advantage of this during the season of growth, when replanting cannot be carried out, will be obvious.

Fruit.

Vines.—When Grape-thinning has been brought to a close, the main requirement will be to keep the lateral growths well stopped back, in order to prevent overcrowding. Should there be no danger of this through the Vines being at long distances apart, then allow the laterals to grow till such danger appears. Inside borders of Vines swelling their fruit will take any amount of manure water, and, as soon as applied, the borders should be mulched with 2 in. or 3 in. of fresh stable litter in order to retain the moisture and supply the atmosphere with ammonia. More than this quantity would prove too powerful and injure the foliage. Ventilate freely in the early part of the day and shut up early in the afternoon, making free use of water to engender atmospheric humidity; give a little air at 7 p.m., and leave it on all night. Grapes that are ripe or ripening cannot have too much air, unless the wind prove exceptionally harsh, which is rarely the case at this time of the year. Usually all atmospheric moisture is recommended to be withdrawn when colouring begins, but we have come to regard a moderate amount as beneficial, inasmuch as it prevents an undue development of red spider should that pest have gained a footing. Pot Vines intended for early forcing next year should now have completed their growth, which will now, as it were, require to be consolidated and ripened by the fullest exposure possible to light and sunshine. Keep lateral growths closely pinched, but the main shoot may still be allowed to grow on unrestrictedly. The plants should still have abundant supplies of root moisture.

Strawberries.—The forcing of these is barely over, and yet preparation must forthwith be made for that of another season. We always layer our first Strawberries in 5-in. pots, in which they are allowed to fruit, and which they do much better than those layered at the same time in larger pots, the reason being that the pots get sooner crowded with roots, and this induces earlier ripening of the crowns, which, as a matter of course, must fruit earlier than they otherwise would do, and as they are forced at a dull and sunless period of the year, no inconvenience arises from their requiring to be watered oftener than those in larger pots. We layer the general stock in 3-in. pots, and as soon as the roots reach the sides of the pot we shift into 6-in. pots. The best soil is moderately stiff loam without any admixture, except a small proportion of bone-dust or horn shavings. Careful crocking, to admit of free drainage, is imperative, as is also firm potting. After potting place the plants in an open position, well supply them with water, and keep all runners picked off as soon as they are produced.

Peaches and Nectarines.—Go over these out-of-doors, and if the fruit is still too thick remove more, as also superfluous shoots, but on no account take away too much leaf, for in the season this is worse in its effects upon the trees than the opposite extreme of neglecting to disbud them. Continue to use the garden engine or syringe two or three times a week, wetting the under sides of the leaves. If this is attended to little injury will be done by thrips and red spider, the worst enemies these fruits are affected by, and which not only materially injure the present crop, but weaken the trees, thereby seriously affecting them in after years. These fruits will be benefited by mulching the ground with half-rotten manure. This is easily applied where the borders are not cropped with anything over the roots.

Keep the hoe at work amongst bush fruits, so as to destroy weeds as they appear. It sometimes happens that there is negligence in this respect, under the impression that the bushes do not suffer from the presence of weeds as culinary vegetable crops do. So far as intermediate effects go this may be the case, but, wherever they are allowed to grow, they exhaust the soil much more than ordinary cultivated plants do; and to let any part of a garden become foul is simply a direct waste of the manure used, of which even bush fruit stand in need, although not to the same extent as vegetables. It is well to observe that if any portion of their garden, however small, be allowed to become a nursery for weeds, the seeds will be scattered by the wind in all directions, and will cause endless trouble afterwards, whilst the pleasure derived from the appearance alone of an orderly, well-kept garden is worth consideration and all the care that can be bestowed upon it.

Vegetables.

It frequently happens that at the time of preparing the ground there may have been a scarcity of manure, of which some crops have not received a sufficient quantity. Where this has been the case, make up the deficiency by the timely application of liquid manure. This should take place at the middle stages of growth after the plants have taken a fair hold of the soil and are growing away freely, and when strength will be imparted at the time it is most required. It is, however, necessary to be cautious in the use of manure water; it must not be applied too strong, for plants, unlike animals, have not the power of rejecting the food that is given them, which in a liquid state goes direct to the roots, and is of necessity absorbed by them, even if their destruction be the result. If manure of a solid character—such, for instance, as that of fowls in a crude state, or guano that is lumpy and insufficiently broken—be dug into the soil, the case is somewhat different; the roots will not enter it, but will run in other directions to escape, as it were, the dangerous diet set before them. A little reflection upon the nature of the particular plant to which manure water is to be applied will, in a great measure, be a safer guide as to the strength of the solution it is able to bear. As a rule, rampant-growing subjects will stand a much stronger mixture than weak growers—Rhubarb, for instance, being benefited by it at a strength that would injure Peas. Runner Beans may receive it stronger than the weaker-growing dwarf varieties; but in all cases it is better to be on the safe side, and rather make the solution too weak than too strong.

Parsley.—A little Parsley should now be sown on well-prepared rich ground; sow in rows 15 in. apart. This will not be disposed to run to seed so soon in the spring as that which was put in earlier. Thin out the early-sown plants, leaving them 9 in. or 10 in. asunder. If this is attended to, in time there will be little to fear from canker at the root, which usually occurs when the plants are overcrowded. When Parsley is given sufficient room it can be kept through the winter with half the trouble and much greater certainty than where it is starved and weakly.

GLASSHOUSES & FRAMES.

LOBELIAS FOR WINTER FLOWERING.

I WOULD call attention to the fact that the bedding varieties of Lobelia form excellent subjects for the embellishment of the conservatory or cool greenhouse during the late autumn and early winter months. When the outdoor season for flowers is past, anything in the shape of bloom is welcome, and the fact of there being a scarcity of blue flowering plants at that time of year renders the Lobelia especially valuable. Not only does it form a pleasing contrast to the other flowering inmates of the structure, but the individual blooms, when mounted up in small clusters and surrounded with appropriate foliage, may be employed with good effect in the formation of hand bouquets. Where the Lobelia is much employed for bedding-out there generally remains a surplus stock of plants, which, if potted at once into 6-in. pots, will in the course of the summer grow into good specimens. Pot them in a free, rather rich compost, and plunge the pots up to the rims in an open sunny situation. About the middle of August cut all the blooming shoots off. As soon as the plants break again administer manure water twice a week, and by housing-time fine masses of foliage will have formed, capable of producing continuously up to Christmas a quantity of fine blooms. The effect of these masses of blue when seen in combination with other plants is very good. When the plants have done blooming they should be cut over and placed in a light situation in a cool structure.

If they consist of named varieties which it is desired to propagate, they will, if introduced into gentle warmth about the middle of January, furnish a quantity of sturdy, healthy cuttings. Such plants as may not be needed for this purpose should be shifted by the beginning of February into 8-in. pots, to be placed in a warm house near the glass, and brought along into bloom at an early date; or they may be kept in a cool house. These large specimens, coming into bloom as they do at an early period of the year, really produce a grand effect. If well and liberally treated, the foliage droops down and partially clothes the sides of the pot, in which conditio

they are especially well adapted for furnishing small vases, jardinières, &c. Where it is desired to create an immediate and brilliant effect in the flower garden, such specially-grown specimens will prove of great service. A collection of varieties, well grown in early spring, carefully hardened off and planted out at the same time as the ordinary run of bedding plants, and placed in the open air, would form a telling feature at a time when small plants had scarcely commenced to grow away freely. Those who may not have plants to spare might sow seed, and put three or four good healthy young plants in a 6-in. pot. J. C.

Campanulas for Growing in Pots.—The dwarf perennial Campanulas merit much more attention than they commonly receive. Equally pleasing either in pots or borders, they are especially useful for the former on account of their neat, dwarf, compact habit and portability. My collection is not a large one, but it includes several very fine kinds, of which C. turbinata is the chief parent, and some of the smaller but hardly less effective sorts. These Campanulas are eminently summer-blooming plants, and therefore need no house protection; they thrive well in large pots, and are especially suited for a large vase until the bloom is over. One of the most pleasing kinds, and specially useful as a vase plant, is the semi-trailing C. Barrelieri; small plants of this planted close up to the side of a vase would make a pretty edging for some of the white sorts, such as C. pumila alba and Henderson's White, both possessing great purity of colour, and being free bloomers. These Campanulas may be readily propagated either by division of the roots early in the year, or by cuttings made of the young growth when about 2 in. in length. If these be taken off with a sharp knife just beneath the mould, and be placed in sandy soil in a cool house or frame and shaded for a few days, they will soon become rooted, and make good flowering plants the same season. Perhaps the earliest is the well-known Campanula garganica, a dwarf and slightly-spreading kind. Its foliage is rounded and somewhat laciniated, its flower-stalks about 6 in. in height, and bearing a great profusion of small pale blue bells with curved lips. This variety generally blooms in June. Next comes the pretty pure white C. pumila alba, which is even more dwarf than the preceding, and produces in great abundance flower-stems 6 in. or so in height, bearing many pure white bells: this is a real gem. C. turbinata is the parent of several kinds, and is itself a variety of great value. In habit it is exceedingly dwarf and dense, the foliage not reaching a greater height than from 2 in. to 3 in. The flower-stems do not exceed 4 in. in length, and are surmounted by large erect bells of a bluish-purple colour about 1½ in. in diameter. Well-established plants of it flower freely. C. turbinata hybrida has a dense, but more robust growth; its flowers are borne in great abundance on stems 9 in. in length. They are about the size of those of C. turbinata, but are rather more expanded and slightly paler in colour. C. turbinata macrocarpa has larger foliage of a pale green hue; its flowers, too, are larger than those of the preceding kind; they are borne on stems 12 in. in height, and are in colour intermediate between the above two sorts. C. turbinata cœrulea has a close, robust habit, with flowers the size of those of C. turbinata, opening white, and deepening to a pale mauve; they are borne on erect stems, from 7 in. to 8 in. in height; it is a very pleasing kind. C. turbinata floribunda is a very pale blue form of C. macrocarpa, not quite so robust, but a perfectly distinct kind. C. turbinata Dicksoni is a very beautiful variety, moderately robust in growth, and has large, almost pure white flowers, borne on stalks 9 in. in height; a very effective kind. C. Hendersoni alba has a neat, erect growth, and pure white flowers of medium size, borne on stems about 10 in. in height; a very charming variety. All Campanulas of the turbinata section produce upturned bells on erect or nearly erect stems. Last of the collection is the pretty C. Barrelieri, the latest to flower, coming in about a week after C. turbinata. It has a dwarf creeping habit, producing medium-sized, mauve-coloured bells in great abundance, and admirably adapted for vases or hanging-baskets.—A.

Fuchsia fulgens.—Just now we have several very fine specimens of this plant in full flower, and I certainly think this is one of the best of the Fuchsias a person can grow. The flowers are produced in bunches at the end of the shoots, and are about 2 in. in length, of the most brilliant scarlet, while the petals are of a much darker hue. The leaves are very large, and when fresh of a bronze shade, gradually becoming a light green. This Fuchsia flowers freely; it is easily grown, and should be in every greenhouse.—W. A. G.

BEGONIA SCHMIDTI.

THIS is a species which has been named by Dr. Regel, of St. Petersburg, in compliment to Mr. Schmidt, of the firm of Haage & Schmidt, of Erfurt. It grows about 1 ft. high, and is of a half shrubby habit, with rather slender branches, which in June and July are covered with a profusion of white and rose-tinted flowers. Its leaves, which are rather small and hairy beneath, are of a dark metallic-green above, and the branches and stems have a reddish tinge. Messrs. Haage & Schmidt remark—"The longer we grow it the better we like it, for the plants which were raised in July, 1878, from seed began flowering in March, 1879, and since that time they have not ceased to bear flowers, not only a few single ones, but rich trusses of very graceful pale pink blooms, which will be much valued for cutting when it becomes better known." It is

Begonia Schmidti; showing habit of plant.

a kind which will doubtless find favour among owners of small greenhouses and window gardens. It can doubtless now be easily obtained at any good London nursery.

MIGNONETTE IN WINTER AND SPRING.

IT is needless that I should dwell upon the merits of the Mignonette. The fragrance which the flowers exhale is of such a sweet and refreshing nature as to render the presence of the lowly, unassuming plant almost indispensable in gardens, large or small. There are few who do not attempt the culture of this fragrant flower during the summer season; but from what I have observed I am inclined to believe that comparatively few make the attempt to secure a supply of it at that period of the year when its grateful perfume would be doubly welcome. There is really little more trouble in producing good Mignonette during the winter months than at any other season of the year; it is a question of sowing seasonably, the after treatment presenting no more difficulties than that accorded to the ordinary run of bedding plants. Amateurs and growers generally who may possess but the convenience of a small greenhouse may rest assured that they need no further accommodation for the growth of Mignonette in the winter season. Even those who have only a cold frame may undertake its culture with a fair prospect of success, provided that frost can be excluded, and that strict attention is paid to cleanliness. Damp is a great enemy to the Mignonette; consequently, those who winter it in cold frames must exercise much more vigilance than is necessary when the pots stand upon a shelf in a light airy house. There is one fact which must be borne in mind, and that is, that the Mignonette does not bear transplanting well; consequently, the seed should be sown in the pots where the plants are intended to bloom. The Mignonette also, though rejoicing in a rich compost, dislikes, and never thrives kindly in, soils of a retentive nature. The French market growers, who grow their plants remarkably well, make an almost exclusive use of decayed manure, some four years old, and which has been well turned and sweetened by frost and sun. The Mignonette roots with great freedom in this compost, and attains great luxuriance of foliage, with correspondingly fine heads of flowers. For spring-grown plants I would advise the employment of such a rich mould.

When the functions of the plant are active and the soil dries out quickly, there is but little danger of its becoming sour. In the winter season, on the contrary, unless very careful watering is practised, the roots are apt to become torpid, and the foliage turns yellow. I would, therefore, prefer a compost which might be relied on to remain in a sweet condition, even if somewhat deficient in nutritive properties. A mixture consisting of half leaf-mould and half loam and decayed manure in equal proportions, adding thereto a goodly portion of silver-sand, will, if all the ingredients are in a sweet condition and well incorporated with each other, and if ordinary care is exercised in watering, suffice to form an excellent and safe-rooting medium. I should advise that pots not larger than 4½ in. across be employed. They should be well drained and the soil shaken down firmly—not pressing it down, however, with the fingers, and making the surface firm and level. The first sowing may be made about the latter end of August. The plants from this sowing will be in full bloom about the time when flowers in the open air will have become scarce. It is a good plan, where cut flowers are in much request, to sow a good number of pots at this time, and in the first week in September. As soon as the first frosts arrive they may be sheltered in an orchard house or some such place, and will furnish an abundance of bloom during the late autumn and early winter months. Successive sowings, made weekly during September up to the first week in October, will keep up the supply, the plants of the last two sowings coming, as a rule, into bloom early in the spring. As soon as the plants are fairly up, thin them out to three or four in each pot, with the exception of the two latter sowings, which may be left rather thicker. Place the pots in a sunny situation, attend carefully to watering—encourage them, in fact, to make sturdy, robust growth—and allow them to remain in the open air until the advent of frost or inclement weather, when they should be placed in a cold frame, so that heavy rains may be warded off. About the last week in October is the proper time for placing the plants in their winter quarters, the best place being a shelf, where they get the advantage of every ray of light, and where they at the same time enjoy a free circulation of air around them on all favourable occasions. Thus situated, the foliage will retain its verdure, and the flower leaves will develop satisfactorily. On no account should artificial heat be resorted to to hasten its progress. The house must be kept quite cool, ventilating freely on all favourable opportunities.

The Mignonette is subject to the attacks of an enemy which, if not destroyed in time, will in the course of a few days completely ruin the plants. This is the larva of a moth, the eggs of which are deposited before the plants are housed, and, being of much the same colour as the foliage, is not easily perceptible until it attains large dimensions. Where the slightest trace of disfigurement is observable the plant should be at once examined, and the culprits will be found concealed on the under surface of the leaves. If the convenience of a light warm house exists, those plants which were raised too late to admit of their flowering in the winter may be placed therein about the beginning of February. They will give a certain amount of bloom, maintaining a supply until the spring-sown plants come into flower. For the spring forcing of Mignonette nothing is equal to a light pit, where the tops may be plunged quite to their rims in leaves or tan. There, in the enjoyment of the

necessary conditions of light, air, heat, and moisture, the plants develop healthy luxuriant foliage, and flowers of the finest quality are formed.

There is a vast amount of difference between a well-grown pot of Mignonette and one which has not received the proper treatment. A perfect specimen should be clothed quite to the rim of the pot with broad green leaves; the growth should be vigorous, yet compact and dwarf, and the flower-spikes should be broad and of good substance. This perfection of growth is only attained when the plants make an unchecked growth, and never know the need of food. As soon, therefore, as the roots touch the sides of the pots, regular waterings of weak manure water should be given. The Mignonette is naturally a free-growing subject, delighting in an unrestrained root-run in generous soil; but, like many annuals, if once the wood becomes dry and hard no amount of good treatment will induce it to make free growth again. A free rich soil, with plenty of moisture, both at the root and atmospheric, are the conditions essential to the successful culture of the Mignonette during the spring months.

J. C. B.

CULTURE OF AZALEAS.

THE Indian Azalea (A. indica) is one of the best hard-wooded plant that an amateur can grow. When once good plants are obtained they give little trouble, require very little heat in winter, and never fail to produce a sheet of blossom in spring and early summer.

General Cultivation.—In regard to the general cultivation of these plants, any that it is desired to get up to a useful flowering size as quickly as possible should at once receive a shift into larger pots, and be placed where they can obtain a little shade with gentle moist heat to urge them on. In potting, make choice of good tough, fibry peat, and see that is in proper condition for use, which is rather on the dry side than otherwise, and then it will admit of being rammed firmly around the old balls without danger of rendering it close and pasty; mix with it a sufficient quantity of sharp silver sand to keep it open and porous. As Azaleas require liberal supplies of water when growing, efficient drainage is the first consideration; but this should in no case be carried to excess, as from 1 in. to 1½ in. of finely-broken crocks is ample, and all beyond that is needless, and occupies room that should contain food for the roots. It often occurs in potting plants of this class that the ball is dry in the middle, and when that is the case it is seldom, if ever, it can be properly wetted through afterwards; and therefore if any doubt exist as to their condition in this respect it is advisable to immerse them for a few hours previously in a tub of water, afterwards standing them to drain. By this treatment, and keeping the balls in a healthy, moist state before potting, the necessity of watering before they get hold of the fresh soil is obviated, which is a great advantage, as it is otherwise apt to become sour from the repeated requisite wettings for the plants. In order to keep them in a free-growing state during the summer, the house or frame in which they are grown should be shut up early in the afternoon, and have a good heavy syringing, so as to wet both the upper and under portions of foliage. As the object is to fill the pots with roots, and to develop the plant in a short space of time, the flower-buds ought to be nipped out, when the shoots will start again; but in no case should any of these be stopped unless they appear unduly strong and are robbing the remainder; and even in that case it is better to bend them down, so as to check the flow of sap and divert it elsewhere, for with a frame or foundation thus laid it is an easy matter to furnish or fill it up after. By the end of September discontinue the syringing, and keep the plants in a temperature of about 40° by night till the beginning of March, when the same course of treatment may be again pursued till the plants have obtained the desired size.

Treatment after Flowering.—In respect to old plants that have done flowering, the first thing to be done is to pick off all the seed-pods. Small and unimportant as these may appear, there is nothing so exhausting to the plants as seed-bearing; and therefore it is of the greatest importance that they should be removed immediately the flowers fall, that the whole energies of the plants may be concentrated on the growth of young wood and in the production of bloom-buds. In the case of those already in pots as large as it is desirable to have them, they may be greatly assisted by giving them an occasional watering with weak liquid manure made from the droppings of deer, sheep, or cows; but whenever this is used it must be perfectly clear, or it will seal up the surface of the soil and render it impervious to air, which will soon throw the plants out of health. Another way of limiting the size of the plants to the pots and keeping them in good condition after they have exhausted the soil is to cut away a good portion of the old ball equally all round and re-pot in the same size again. This may appear an extreme measure to adopt, but Azaleas do not resent it in the least; indeed, after they have attained a certain age, and under the above conditions, they are considerably benefited thereby, and with such treatment old plants may be kept for many years in perfect health and vigour. When this course is adopted it should be done early in the season, just as they begin to grow, when the formation of fresh root-fibre and young wood and foliage will go on simultaneously. After this treatment keep the plants heavily syringed and shaded, and in a house where they can be kept close for a time till they fairly start. It is surprising the amount of heat Azaleas will stand and enjoy while making their growth and setting their flower-buds, provided the moisture they receive is in proportion; and it is from lack of these two essentials that we so frequently see the flowers so diminutive in size, as the buds do not receive the proper amount of assistance to develop them fully before winter sets in. This being the case, they should be kept under glass and treated in the same manner as to water, syringing, &c., as those that have had their balls reduced till the end of July, or even later if the buds do not appear well up, after which they may be ranged in some sheltered place out-of-doors, where they can be shaded by a tree or tall-growing shrubs for a few hours during the hottest part of the day. There they will enjoy the genial night dews and ripen up their growth better than if they remain the entire season in a house; but when out-of-doors there are two things to be guarded against, viz., continued heavy rains, that often set in towards the autumn, and dryness at the roots, caused by the hot air acting on the sides of the pots. The first may be guarded against by leaning the plants on their sides, and the second by putting them in a pot a size larger than the one in which they are growing, and by frequent examinations as to their condition, making sure at all times to give them sufficient water when they require it to thoroughly soak the whole of the ball. Plants that are not potted may be put out-of-doors some weeks earlier in the season, provided they have made good growth.

S.

Spray of Begonia Schmidti.

Cool Orchids.—Now is the time to keep these cool. Anything in the shape of oppressive heat, during July and August particularly, will do more harm than indifferent treatment for the other ten months of the year. Our climate in summer is, if anything, too hot for such Alpine Orchids as Odontoglossum Alexandræ, Pescatorei, and triumphans, and similar kinds; consequently abundance of moisture, particularly in the atmosphere, must at this time prevail. To keep down the temperature shading must be resorted to, and it will add much to the coolness of the house if the shading be raised 2 ft. from the glass, in order that a current of air may intervene between the two. Attention to this will prove highly beneficial to the plants, which, thus treated, will distend their pseudo-bulbs to a great size, other conditions being favourable. The leaves will become broad and dark in colour, and will stand up instead of falling down by their own weight, as is too often the case. If the atmosphere be properly supplied with moisture, there will not be much necessity for giving

great doses of water at the roots. I find a layer of Sphagnum an excellent bed in which to plunge the pots half-way down; it keeps them moist and looks well as it grows into a cushion of emerald velvet, encouraged to growth by the constant supply of moisture.—J. A.

ANSWERS TO QUERIES.

2334.—**Pelargoniums for Show.**—Three seasons of growth are necessary for the formation of a Pelargonium for exhibition. As soon as the rooted cutting is potted off and has made some five or six leaves, the point of it should be pinched out; side shoots will then be formed, which, if the plant is shifted on as needed and kept growing freely, will speedily attain strength and substance. These shoots must in their turn be stopped back. Supposing that the cuttings have been potted off in October, stopped the first time, and the plants kept growing along gently in a light airy house in a temperature of 55° by day, they will need shifting in December, and may be stopped the second time in January. By March the pots will again be full of roots, when a further shift may be given, pinching back the shoots once more and for the last time as soon as the necessity for so doing is perceived. By the middle of July growth will have been completed, and the plants may be turned out into the open air to mature their wood. As soon as this has attained the proper amount of ripeness, the shoots should be pruned back to the firm hard wood, placing them where they can be sheltered from heavy rains. When they have fairly started into growth shake away the old soil, prune back the old roots slightly, and replace in a size smaller pot. Keep close for a few days until root-action has commenced, and then gradually inure the plants to full exposure. House them by the latter end of September, and by the end of October they will, if all has gone well, be ready for shifting into 8-in. pots. A piece of wire should then be fastened round the rim of the pot, and a few stout stakes being laid across the pot and attached firmly to the wire, a piece of Willow may be run round and attached to their extremities, thus forming a trellis, to which the shoots may be tied down as they grow. The operation of training must be conducted with caution, tying down a few shoots at a time and keeping them as widely apart as possible, so that sun and air may play freely upon the wood, thus rendering it short-jointed and vigorous. Towards the middle of November pinch out the shoots, after which time no further stopping must take place. These plants may, if so desired, be shown the following summer; but it is better to allow them another season's growth. Treatment the second and third year will be pretty much the same, only that those plants which are intended to be shown in May and in the early part of June must not be stopped at all, whilst those reserved for July exhibitions will need to be pinched in December. For the early shows, early flowering kinds must be grown; and the temperature must be regulated so that the flower-trusses are well up by April. During the early spring and summer months free ventilation must be given, avoiding cold draughts, and frequent waterings with clear soot water or liquid manure of some kind should be administered as soon as the pots get full of roots. Every flower-truss should also be tied to a neat Willow stake as soon as the buds begin to open. Zonal Geraniums require a somewhat different treatment. Cuttings struck either in the autumn or spring should be grown along in gentle warmth during the early spring months, stopping them as required. By the end of May shift into 6-in. pots and place in the open air, plunging the pots up to the rim in ashes or Cocoa-nut fibre. Attend to watering, stop back the stringent shoots and tie them out, bringing them down as much as possible to the rim of the pot, at the same time picking off all flower-trusses as they appear. House them in a light structure, not allowing the temperature to become too low. In October they may be shifted into their blooming pots, and should not be stopped after that time. With respect to the time of flowering, that has to be regulated by the temperature maintained in the structure. As a rule, the flower-trusses will be showing about the beginning of April, the plants then requiring about two months to come to perfection, that is to say, by the beginning of June. If required at an earlier date a higher temperature will have to be maintained.—J. C., *Byfleet*.

2322.—**Raising White Thorns.**—Collect the berries when ripe, and store them away in dry sand until the next spring twelvemonths; by that time the fleshy portion of the berries will have decayed. Sow in March in drills about 9 in. apart in well-stirred ground, or prepare a bed some 4 ft. in width, well breaking the soil with a steel fork. If the natural staple is of a heavy adhesive nature, lighten it by the addition of some leaf-mould, wood ashes, or something of a like description. Choose a dry day in March for sowing. Scatter the seed broadcast, tread it well in, and cover with about 1 in. of fine mould, finishing off by patting the same down firmly with the spade. Keep the bed free from weeds during the summer, and as soon as the foliage drops, set the young seedlings out in lines in deeply dug, well manured ground, about 15 in. apart, and 9 in. from plant to plant. By the following autumn they will have grown into good strong plants, fit for making hedges or for any desired purpose.—J. C. B.

2331.—**Failure of Rose Trees.**—If the plants in question are not growing they are probably dead, having succumbed to the severe winter. The best way will be to root them up and replace them with others. There is a great mortality amongst Roses this year, their constitutions having been so weakened by the sunless summer of 1879 and the severe frosts of the succeeding winter, that they have been unable to resist the drying winds which we have experienced this spring.—J. C. B.

2319.—**Vinegar Plant.**—You labour under a false impression with respect to the Vinegar Plant, which is simply a fungus which forms spontaneously upon vinegar or upon wine which may be turning acid. A portion of this fungus placed upon any liquid which it may be desired to turn into vinegar will facilitate the operation. Its botanical name is Penicillium glaucum. There is no known plant which will supply vinegar.—J. C.

—— This is of the same class as the Yeast plant, and flourishes in the bottoms of vinegar in casks.—ACETUM.

2271.—**Oleanders not Blooming.**—I have always understood that the roots of this plant throw out a poisonous matter, which is prejudicial to their blooming in the same soil more than one year. I usually remove my plants from the pots in March, and, placing them under a stream of water, thoroughly cleanse the roots, and then repot them in peat, loam, and sand, and have never failed. They should be watered at the root twice a day and syringed overhead every morning.—W. E. LEE.

2325.—**Marechal Niel Rose.**—"Salopian" complains of Maréchal Niel losing its buds. I have one covering 21 ft. of south wall. It is worked on the Dog Rose. I give it no protection in winter. I have had an abundance of the finest blooms since the first week in May. I have had the plant about fifteen years. Let "Salopian" try my plan.—T. J. BLOFELD, *Norfolk*.

2255.—**Prickly Comfrey.**—About one hundred crown sets of the new Russian variety, would, if planted in a clay soil, yield sufficient food for a horse and pony. It must be planted 3 ft. between each crown; there would be sufficient to spare some leaves for the poultry. At the first break in winter the leaves come forth, and they will stand several degrees of frost if it is dry weather.—T. C.

2333.—**Bouvardias for Bedding.**—Bouvardias would not be satisfactory thus employed. They are winter-flowering subjects, being of great value for conservatory or room decoration during the dull months of the year. They may be grown in the open air either in pots or planted out during the summer months, but should be placed under cover by the middle of September.—J. C.

Although the following questions are answered by the Editor, we shall be obliged to any of our readers who may think well to answer them again.

2372.—**Cucumber not Growing.**—I have got a Cucumber which I planted a month ago in a cold frame; it has not grown at all since. I have watered it every day.—D. [The cause is want of heat. Sprinkle it every afternoon with tepid water, and shut up the frame, say, at three o'clock. Keep it rather close during the day, and shade slightly from hot sun. It will probably grow as the weather gets warmer.]

2373.—**Loam.**—What is the soil so often described as loam or sandy loam, and how to be procured?—A. H. L. [The top spit of a pasture laid to rot for a year is the best kind of loam. Sandy loam means, of course, loam containing a quantity of sand. Yellow loam is the best, and may be bought ready for use. See our advertising columns.

2374.—**Bottom-heat for Plants.**—*Mark P.*—Geraniums, Fuchsias, Petunias, Calceolarias, Balsams, Verbenas, Coleuses, Scarlet Salvia, Alternantheras, Primulas, require no bottom-heat. Place them on coal-ashes in your frame; keep them near the glass; give plenty of air and water.

2375.—**Lily of the Valley.**—Ought large and thick beds of Lily of the Valley to be left alone or transplanted? if the latter, when is the best time to do so?—H. B. [If the plants flower well we would let them alone, applying in autumn a coat of rotten manure.]

2376.—**Stopping Cucumbers.**—When is the right time to stop the growth of Cucumber plants, so as to throw off side-shoots? or would you allow the main shoot to run out and have the fruit on it instead of the side-shoots? My frame has two lights of about 6 ft. by 3 ft. each.—W. G. L. [Stop the leading shoots at once, and also stop all side-shoots at one joint past the fruits when they show themselves.]

2377.—**Strawberry Layers.**—Some of my Strawberry layers planted last year have borne no blossoms this spring, while others with exactly the same treatment are crowded with fruit. Should I dig the barren ones up, or keep them on? I have been told that only those layers which grow nearest their parent plant are fruitful; is this so?—METHUSELAH. [Dig them up and replace them with runners from your fruitful plants. It matters little whether a runner is near the parent plant or not; but runners should always be taken from fruitful plants only.]

2378.—**Best Time for Planting.**—What is the best time for planting Hepaticas, Christmas Roses, and Belladonna Lilies?—R. A. B. [September.]

2379.—**Filling Blanks in Asparagus Beds.**—Can roots be put in to fill up blank spaces in October? The books say spring is the best time, but the vacant spaces are not distinguishable; whereas by putting in before the heads are cut down in October the vacant spaces can be perceived. [Could you not place a stick, or in some other way mark the vacant spaces? Spring is decidedly the best time.]

Zonal Pelargonium.—*Kappa.*—We advise you to wait until the exhibition of the Pelargonium Society, which takes place on June 29. Specimens should reach the superintendent of the Royal Horticultural Society's Gardens, South Kensington, on the morning of the show.

Tree Mignonette.—*Lover of Mignonette.*—Sow at once in small pots, placing about three seeds in the middle of each. When well up pull out the weakest, leaving one only. Pot into larger pots as necessary, keeping all flowers regularly pinched off, and also occasionally stopping the shoots to get the plant bushy and of good shape. If standards are needed keep all the shoots but the centre one rubbed off, and when the desired height is reached, stop the centre one also, and in turn stop the shoots which will be produced near the top of the centre shoot till a bushy head is formed.

Quassia.—*A. B. G.*—Boil the Quassia chips for fifteen minutes or so. 4 oz. to the gallon is a good strength, adding 4 oz. of soft soap to the gallon as the liquor cools.

Saxifrages.—*Wilts.*—These are hardy plants, thriving best in deep sandy vegetable soil on rockwork or raised mounds. A partially shaded situation suits them best.

Manure Water for Celery and Vegetable Marrows.—*W. H. D.*—No kind of manure water is better for this purpose than the drainage from a manure heap or stable. That fresh from the stable must be diluted before use. A bag of soot soaked in the liquor is an improvement.

Mint Turning Yellow.—*Southportarian.*—Cut it down close to the ground and apply a top-dressing of well rotted manure. It may then grow better.

Seedling Solanums.—*J. E. G.*—Harden them off, and then plant them out-of-doors in a bed of rich soil, and lift them in autumn.

Fuchsia Earl of Beaconsfield.—*A. B. initio.*—This varies in colour according to the season of the year, and we also think there are several varieties being sold under the same name. Mr. Laing, of Forest Hill, has, we believe, the original plant of it.

Potting Orchids.—*W. A. B.*—You may pot them at once. Read the article on Orchids in last week's GARDENING.

Gardenia with Deformed Flowers.—*W. A. B.*—The plant has received a sudden check when forming its flower-buds either by insects, change of temperature, or dryness at the roots.

Young Vines not Growing.—*G. W. H.*—Keep them well watered at the root, and keep a moist, airy atmosphere in the house, and they will gain strength as the summer advances.

Cucumbers Gumming.—*J. A. J.*—Want of heat will sometimes cause this. Apply new linings to the frame; also scrape off the gum, and rub the stem over with quicklime.

Sulphuring Hot-water Pipes.—*L. S.*—This should only be done in cases of mildew or red spider. Get flour of sulphur, and mix with water to the consistency of thin paint. Apply it to the pipes with a brush.

Planting Asparagus.—*Two Good Beds.*—See answer No. 2250, last week.

Glazing Without Putty.—*H. E. F.*—You should visit some place where this system is in use to be able to judge of its merits, and see how it is done.

Mushrooms.—*Novice.*—The manure from horses fed on dry food is better than that from horses fed on green food. The manure from entire horses is considered best, but the other will give good results.

Alpha.—Keep the paths and stages of the house well watered, and give plenty of air. You heat the house too much. Very little fire-heat is needed now for ordinary greenhouse plants.

Campanula.—Send us a bit of the plant, with flowers if possible. You do not give us any idea of what the plant is like.

Bindweed in Gardens.—*Peshtaff.*—Pull all up you can, and afterwards keep the ground well hoed in order to prevent its reappearance. By persevering in this direction you will in time get rid of the weed. This is, in fact, the only true way to exterminate it.

Strawberries for Forcing.—*Peshtaff.*—Charles Napier is the best kind you can grow, unless you want a very early sort, then have Héricart de Thury or Keen's Seedling. Runners should be layered at once in small pots or pieces of turf, and when rooted they should be severed from the parent plant and potted into 5-in. or 6-in. pots.

Roses not Blooming.—*Y. Z.*—Roses everywhere are very poor as regards bloom this year, but they may make good growth, and thus give a good bloom next season.

Melons not Swelling.—*R. P.*—Pinch out all the growing points of the plants, and thin out weakly growths; also keep all flowers picked off. Give a good soaking with tepid water.

Tropæolum tricolor.—*A Vicar.*—We can assign no reason for your plant dying off; only that probably it had received an over-dose of water and the soil had got sodden; or it might have been suddenly exposed to the sun.

Gooseberry Caterpillar.—*R. G. F.*—The Hellebore powder should be washed off with a syringe after it has been on the trees for a day or so. It will not hurt the fruit. We have never tried it on Currant trees.

Market Gardening.—*T. E. N.*—The extent of ground you take must depend upon the capital at your disposal. You can make more profit comparatively out of a few acres well cultivated than out of a greater extent badly cropped. To realise £200 a year profit as a certainty you would need at least 10 acres. Shaw's book on "London Market Gardens," advertised in our columns, would be a great assistance to you.

Names of Plants.—Whilst we are always pleased to name plants for our readers we are bound to remind them that we can only do this when fair specimens are sent. We cannot undertake to name florist's flowers, such as Fuchsias, Geraniums, &c., nor more than three of any kind of plant at one time.——*Factotum.*—1, Franciscea calycina; 2, Tabernæmontana coronaria; 3, Dalechampia Roezliana rosea; 4, Abutilon vexillarium; 5, Diosma Ericoides; 6, Rhynchospermum jasminoides; 7, Selaginella cæsia arborea; 8, Selaginella cæsia; 9, Pteris argyrea; 10, Nephrolepis exaltata; 11, Pteris serrulata cristata; 12, Stag's-horn Fern (Platycerium grande); 13, Adiantum scutum. Thirteen specimens at one time is too bad.——*Rose.*—Limnanthes Douglasi.——*S. G. F.*—Fern-leaved Beech.——*A. M. R.*—1, Saxifraga cæspitosa; 2, S. pentadactylis; 3, S. cæspitosa hirsuta; 4, S. hypnoides; 5, S. Aizoon.——*T. G. R.*—1, Zonal Pelargoniums; 2, Fuchsia procumbens; 3, Mesembryanthemum species, which we cannot say.——*Ganvar.*—A species of Albuca; cannot name without leaves.——*A. M.*—Cannot name without flowers; please attach numbers to specimens when sending again.——*M. E. T.*—Pinguicula vulgaris. ——*Mrs. M.*—6, Begonia Weltoniensis; 7, B. fuchsioides; 8, B. Saundersi; others not in flower. They will only succeed out-of-doors during summer.——*Subscriber.*—Cyperus alternifolius variegatus; mix plenty of sand with the soil.——*T. E.*—Solanum Dulcamare, berries poisonous.——*Walter Edwards.*—1, Peperonia arifolia variegata; 2, Peperonia of some kind; 3, Begonia nitida.

QUERIES.

2380.—**Improved Flower Gardening.**—Living in the suburbs of a large town, and having a very pretty garden about 60 yards long, consisting of croquet lawn, flower-banks, and beds laid out in Grass, with reserve corners for Ferns, &c., I read with much interest an article written by "Amateur M.," and should feel very grateful for instructions of how and when to plant some of his flowers that I am unacquainted with—Polyanthus, Primula japonica, Oriental Poppy, Day Lily, Campanulas, Scarlet Linum, French Poppies, Ox-eye Daisy, Chrysanthemum Etoile d'Or, Zinnias, Anemone japonica alba. Having neither greenhouse nor cold frame, I raise seedlings in small boxes covered with glass. I find, as a rule, planting seeds in the ground a failure, or coming so late they are of little use. I, like "Amateur M.," do not mind any amount of trouble, but cannot boast of having my flower-beds always as bright as I should like to see them. Any hints of how to keep them so will be read with much pleasure. Perhaps I should mention there are nine beds, each having a standard Rose in the centre. —LOVER OF FLOWERS.

2381.—**Clay's Fertiliser.**—Can any one who has tried this tell me what quantity should be used per acre? whether it is a good manure for garden, and especially market garden, crops? whether it is a manure that does not take as much out of the land as it puts in? and whether it is suitable for Wheat, Peas, Onions, and root crops in large quantities? I am desirous of comparing it with other manures I am acquainted with, both as to cost per acre and success in competition with other plant foods, and if any of your numerous readers can give the required information, it may make some difference what manure I and others may buy for next season. Is it a manure that permanently improves land, or simply stimulates a crop?—V. A. V.

2382.—**Plants for Exhibition.**—I should like to exhibit at our annual flower show, which takes place the last Saturday in August, some Penstemons, Antirrhinums, Stocks, Asters, and Pansies, with perhaps some Geraniums and other flowers in pots; and as this is my first attempt at anything of the sort, I should be glad of some advice on the subject. Should they be liberally supplied with liquid manure, &c.? and when should I let the Geraniums go into flower? I possess a very small greenhouse without any heating apparatus.—S. A. H.

2383.—**Spiræa japonica Failing.**—I have a Spiræa japonica, the root of which I bought last autumn, which I thought was doing splendidly, but all of a sudden the flower-spikes began to turn black and all crumpled up, as likewise did the leaves. What was likely to be the reason of it?—S. A. H.

2384.—**Celery for Exhibition.**—Will some one inform me of the best means of blanching Celery for exhibition?—N. S.

2385.—**Planting Honeysuckles.**—Will any one tell me the best time to take wild Honeysuckle from the hedges to plant in London? I tried some last autumn and this spring, but they have all dried up. What soil do they require?—A. D.

2386.—**Lily Failure.**—When living in Hampshire some time ago we grew some White Giant Lilies which bloomed splendidly there. About six years since we migrated from Hampshire into Wiltshire, took the Lilies with us, and planted them in a border in front of some common Laurels. They grew rapidly until the flower-stem reached the height of 18 in. or 2 ft.; at this stage large brown spots appeared on the leaves and stem, which, no doubt, were the cause of the immediate pining and subsequent death of the plants. About eighteen months ago we uprooted the Laurels for the purpose of making a herbaceous border 130 ft. long and 17 ft. wide. This border was trenched 2 ft. deep; at the bottom was a good layer of horse and cow manure; the upper and middle layers consisted of manure mixed from the hot-bed. The soil is rather strong and the border is inclined slightly to the north; but behind, about 50 yards distant, a good belt of trees shelters it from any disastrous effect of the north winds. Through the middle of the above border were planted two rows of Lilies, and this time, both in front and behind, other things were planted which are doing very well. The White Lilies at first grew rapidly, just as the others had done, and, like the others, they, too, have this year dwindled and died. I have examined the bulbs; nothing seems to have attacked them, and they present a healthy appearance. I shall feel obliged if any reader will kindly render me effective assistance in remedying this evil.—C. W.

2387.—**Ammonia for Plants.**—Having seen spirits of ammonia recommended for pot plants, would any of the readers of GARDENING having a practical knowledge of the nature of spirits of ammonia inform me what quantity of spirits to 1 gallon of rain water would be safe to apply to Fuchsias, Geraniums, &c.?—GREENHORN.

2388.—**Grapes Failing.**—I have a Vinery, about 30 ft. by 18 ft., lean-to, high walls on east and north sides of it; six Vines put in four years ago; border, 7 ft. inside, 9 ft. outside; drain at the bottom; bones in border. Last year there were a great many Grapes, but seemed to dwindle away, and mildew set in; this year about six bunches are all there are. Heat kept up in winter between 50° and 60°. Can any reader please tell me what is the cause, and the remedy for this?—D. W. G.

2389.—**Manure Water.**—Will "Public Analyst" (p. 140, GARDENING ILLUSTRATED) inform me how much sulphate of iron (by weight) will be required to fix the ammonia in 1 gallon of urine?—CONSTANT READER.

2390.—**Cats in Gardens.**—If any one, knowing the law upon this subject, would kindly write upon it in GARDENING of an early number, I am sure they would confer a boon upon those persons having town gardens, and who are, night after night, pestered with this abominable nuisance to gardens. Suppose I give notice, in writing, to those persons about me keeping cats, that their liberty during the night is a nuisance to me and cause damage to my property, and that if allowed to continue to annoy me I shall destroy any found on my premises, will the law allow me to use such means as I may prescribe to rid the pests? "R. G.," in yours of the 26th ult., gives us an account of the trap and water cure, which I consider very good; but how is the trap made that you would catch a cat in?—W. M. B.

2391.—**Hollyhocks not Growing.**—Some Hollyhocks, which have been planted out for a month at least, throw up very large leaves, each on a long stalk, while the main shoot of the plant does not grow at all. What is the cause of this? what its remedy?—A. H. L.

2392.—**Anemones not Blooming.**—Can any one tell me why my Anemones have not flowered? They were planted eighteen months ago, and last year had a few flowers; this year there is only one, but a very good one. Should they be lifted and replanted? or remain in the bed untouched?—T. B. K. G.

2393.—**Insects in Cucumbers.**—My Cucumber bed is infested with insects, how many sorts I cannot tell, but there are thousands of them, and as soon as the roots get out a little way they are eaten off by these destroyers. Can I kill them by any means without doing harm to the plants? if so, will some one please to tell me what to get and how to use it?—A NOVICE INDEED.

2394.—**Fruit for Exhibition.**—Will some one tell me how to grow Apples, Pears, and Plums for exhibition? The Apple and Plum trees are nailed to the wall. Name of Apple is Lincoln Pippin, and name of Plum Victoria. I want them to be ready by the middle of August.—D.

2395.—**Roses to Flower at Christmas.**—Will some practical man give me any information as to Roses to flower at Christmas? I have some nice plants growing well in 6-in. pots, and some few in 8 in. pots, in a cool greenhouse. Some recommend me to grow them on till August, then give them rest till October, then start them again. Others say keep them growing on steadily right through, pull off all flower-buds (which I am doing daily), and they are sure to flower in December. Then, as to potting, one says have the pots full of roots when you start them in October, another says give them a shift in September, all of which is very puzzling to a beginner. —NOVICE.

2396.—**Blood as a Manure.**—Can any one kindly tell me if bullock's or sheep's blood is good as a manure for flowering plants, and how it should be used?—WILTS.

2397.—**Cobæa scandens.**—I have two plants raised from seed now 1 ft. high. Will some one kindly tell me how to treat them, and how best to train one or both to cover a wall in cool conservatory 10 ft. high by 4 ft. at bottom and over a doorway higher up? Will they grow sufficiently large in pots? and what is best to train them on? and must I pinch it back to keep it bushy?—BUTTERFLY.

2398.—**Annuals for Exhibition.**—Can any one tell me the names of the best six hardy and six half-hardy annuals to grow for cut flowers for exhibition purposes next August?—LOVER OF FLOWERS.

2399.—**Plants for Photographic Studio.**—Can any one inform me what kind of evergreen shrub will grow and look pretty in photographic studio to be used in the trade of a photographer?—ARTIST.

2400.—**Keeping Everlastings.**—Can any one tell me what I can do with white Everlastings to keep them a pure colour? mine always turn brown.—A. J.

2401.—**Climbers for Bleak Aspect.**—Would any reader kindly tell me the names of a few good hardy climbers for an house with a south and east aspect in a very bleak place.—J. E. G.

2402.—**Canadensis sanguinea.**—I have some plants of Canadensis sanguinea the seed-pods of which ought to ripen next week or so. When is the best time to sow the seed, and in what temperature? Will the roots bear early forcing?—STRETTON.

2403.—**Plants for Empty Room.**—I would like to know the most suitable plants to grow in a large empty room with an ordinary sash window.—W. H. D.

2404.—**Triumphal Arches.**—Can any one give me some information on this subject? I want to erect an arch with a span of 13 ft., the height being 10 ft. 6 in. What plants should I use, &c.?—CONSTANT READER.

2405.—**Honeydew.**—Does any one know of a remedy for Honeydew on plants?—V. C. W.

2406.—**Cauliflowers Going Blind.**—I have a fine lot of Veitch's Autumn Giant Cauliflower plants, and I find that more than fifty per cent. go blind. Will some reader tell me why it is so?—NIL DESPERANDUM.

2407.—**Heating a Greenhouse.**—I have built a greenhouse, 5 ft. by 6 ft. Should be glad to know the best way to heat it in the winter. Will the fresh paint injure the plants?—CONSTANT READER.

—— Will any subscriber inform me how a small greenhouse, 5 ft. by 5 ft. by 5 ft., built against the wall, and having a good southern aspect, can be heated during the winter months? I want a simple and cheap contrivance.—Z. D., *Liverpool.*

—— I have a greenhouse 9 ft. by 12 ft. by 9 ft. high. Can any reader inform me the best way of heating it? I am not allowed to have a chimney or make any smoke. Is a petroleum lamp any use? and if so, which is the best?—H. T. B.

2408.—**Making an Asparagus Bed.**—Will some one be so kind as to give me the necessary directions how and when to make a fresh Asparagus bed? my old one appears now of no use.—A SUBSCRIBER.

2409.—**Plants for Shelves.**—What are the best plants to grow on the top shelf of a wooden conservatory stand about 4 ft. from the glass? I have tried Salvias, Balsams, and other things, but nothing seems to flourish there, the plants grow so tall and spindly. Would boxes or pots of seeds do well there?—NANCY.

2410.—**Calceolarias from Cuttings.**—If these are cut down and placed in a pit, like Cinerarias, they will throw up young shoots to make good cuttings. Can any one tell me how this plan will succeed?—ARTHUR.

2411.—**Azaleas not Blooming.**—Can any one tell me why my Azaleas have not flowered this year? They look strong and healthy, and have made a great deal of wood; on one a few flower-buds appeared, but they almost immediately dropped off. They have been kept in a greenhouse, and have had plenty of water. —A. H. L.

2412.—**Double and Single Stocks.**—How can I tell double from single Ten-week Stocks before they are in bud?—T. E.

2413.—**Show Celery.**—Will any practical grower of Celery give me as early as possible the best way to treat above, especially giving information as to supporting the Celery when not earthed up, and also the best way and material used for wrapping, so as to ensure effectual blanching?—A LOVER OF CELERY.

2414.—**Datura chloranthe,** Tropæolum polyphyllum, and Tropæolum speciosum, are three plants which baffle me. Can any one set me right in the cultivation of them?

2415.—**Budding Roses.**—I have a common white Rose in a pot; I want to bud a Maréchal Niel Rose on it. When would be the best time to do it? I want to move it to the back wall of a Vinery; will it interfere with the Vines? and would it do planted in a Vine border? Should I bud it before removing it or after?—B. L. C.

2416.—**Winter Gardening.**—What will remain green through the winter in a border of cold soil?—A. L

FLOWER SHOW IN REGENT'S PARK.

THE second summer exhibition, held on Wednesday, the 19th inst., at Regent's Park, was a very fine one—one of the best indeed that has been held in London this year. The spacious tent was well filled with unusually fine exhibits in the various classes, the entries in which were, on the whole, very numerous. The principal attractions were the grand banks of Orchids, especially those exhibited by amateurs, notable among whom was Sir Trevor Lawrence, Bart., M.P., whose gardener showed such examples as are seldom seen at an exhibition. The miscellaneous groups which occupied the central banks, contributed by Messrs. Veitch, Williams, Henderson, and Laing, were likewise highly attractive. The usual display of stove and greenhouse flowering and fine-foliaged plants and Ferns was on this occasion more numerous, and all, with

but few exceptions, were of high merit. A remarkable feature also was the tuberous Begonias shown by amateurs, which were finer than we have yet seen them; this is a proof that their culture is being better understood, as the collection shown by Mr. Law's gardener was indeed very fine. The display of fruit was good, though not large. Some excellent examples were shown for the leading prizes. The competition for the ten guinea prize offered by the Fruiterer's Company, which was to have taken place on this occasion, was withdrawn, and has been postponed until the occasion of the evening fête (June 30). Altogether it was a fair exhibition, and the judicious arrangement of colour and foliage was very effective, and was moreover increased by the Messrs. Carter's extensive display of annuals in the corridor, and Messrs. Waterer's Rhododendrons in the adjoining tent.

Packing Fruit.—We are requested to direct the attention of our readers to the special prizes offered by Messrs. Webber & Co., of Covent Garden, for competition on the 29th inst., on the occasion of the Rose show to be held by the Royal Horticultural Society at South Kensington. The prizes are £7 7s. and £3 3s. for the best packed three boxes of fruit, to consist of one box of Grapes not less than 14 lb.; one box of Peaches not less than twenty-four; and one box of Strawberries not less than 2 lb. To be booked, carriage paid, at any station over 20 miles from London, and delivered by railway company, addressed to the Superintendent, Royal Horticultural Society, South Kensington. Those of our readers who do not compete for the prizes should, if they are in the habit of sending away fruit, avail themselves of the opportunity of seeing the best ways of packing it.

POULTRY.

Poultry Profitable.—I have kept poultry for seven years, and feel sure they can be made fairly profitable. My method is to obtain, if possible, broods at various seasons, so that eggs may be had all the year. Last year I had birds hatched in May, August, and October. My first May pullets commenced laying November 6 (a cross-bred Brahma Spanish); August pullets first commenced to lay February 15; and one pullet, hatched October 23 (light Brahma, pure-bred), laid her first egg April 11; she has laid every day but three until recently, when she became broody. Forty-two eggs in succession, from a bird now only seven months old, I think very wonderful; this is without doubt, as she has been kept with other pullets only. My birds are well fed, and have a Grass run of an acre. I give Barley twice daily, kitchen scraps, &c., and in the winter warm food once daily.—E. D.

Vermin on Poultry.—M. Lemoin, of Crosne, says that he changes the whole of the material in his nest boxes every six days when the hens are sitting, and powders the floor of the box or basket with sulphur flour. To ensure a good hatch, he finds it necessary that the hen should be comfortable, and also be well nourished, so much so, that he crams them if they will not eat regularly; he does this not only to ensure steady sitting, but to ensure a good supply of heat from the hen's body.—T. C.

—— Go to the nearest chemist and ask for a long-shaped bottle, to hold about 2 oz. of bi-sulphate of carbon. Before you remove the cork fasten a piece of string round the neck, and make a loop to hang it on a nail; when it is hung up remove the cork, and the escape of the vapour in the chicken house will free it and the poultry of all vermin and not injure the fowls.—T. C.

—— In answer to "Subscriber's" inquiry as to whether insects are injurious to chickens, we answer most assuredly they are. Follow out the instructions given in the article on "Insects in Poultry," in GARDENING of June 5, and the birds will soon be free of all insects.

Keeping Brahmas.—Your bird appears to be suffering from cramp. Keep it in a warm dry place; the bottom of the pen should be littered with chaff or straw, and feed liberally with good nourishing food. In the space mentioned, a cock and half-a-dozen hens could be kept, but they would need keeping very clean.

Keeping Ducks.—In answer to "T. T. B." about young ducks, I find the ordinary breed answer best. I rear them till they are six weeks old, and then they are worth 1s. 6d.; if you keep them till they are grown, they would then be worth about 3s. 4d. I have a brood of eight white ducklings which are a month old; also I have just hatched another brood, and two more coming later on, all of which I shall dispose of at 1s. 6d. each. White ducks are supposed to sell best, as they look whiter when dressed for the table.

Disease in Fowls.—If "May" would closely inspect the bird, he would find it is not scurf, as he supposed, but the nits of insects which may be found on the bodies of the birds. These insects irritate the birds, especially round the head; and as the nits are firmly attached in great numbers to the feathers, the birds in scratching themselves often pull out the feathers. A little oil may be rubbed over the head and neck, and plenty of dry earth or mortar, with a little sulphur mixed together for the birds to dust in.

Pea-fowl.—Their ordinary food is the young Grass, but to prevent them straying it is advisable to give them a daily feed of bread scraps. With regular feeding they become as domesticated and harmless as barndoor fowl, and the damage done in a large garden is very small. They require no shelter either in winter or summer, their favourite roosting place being a tree or one of the outhouses.

Enlarged Crop.—It is the crop of "Kate's" fowl, which has become enlarged. This is brought on by keeping the bird without water. When a supply is given they drink too much, and overtax the muscles of the crop, and these, not being able to regain their normal condition, leave the crop to hang down in a loose and most unsightly way. The fact of the hen vomiting, or rather the water running from the mouth, proves that she is often kept short of water. There is no cure for enlarged crops, neither does it produce any pain.

Prolific Fowls.—"Thorburn" says he thinks his hen may be called prolific. According to my hens in general, and one in particular, I do not think so. The one in particular was hatched last August, brought off a brood of nine on April 27, and commenced laying again on May 22.—A LADY.

THE HOUSEHOLD.

COOKING PEAS.

GARDEN Peas, *petits pois*, when young, quickly grown, and fresh, have a delicious characteristic flavour of their own, are rather sweet, and almost crisp when eaten; and maintain these attributes unimpaired if simply boiled in salt and water. Such should be eaten *à l'Anglaise*, the use of the term itself being a tacit admission on the part of the French *chef*, that a simple cooking advocated here, and practised in this country, is often right. All that is produced under this name is a dish of Peas, cooked as described, with a pat of fresh butter and some salt, accompanied by the capital little pepper-mill, which is natural to a French table, and almost unknown here. A morsel of the butter is stirred into the hot Peas, a little black pepper, full of fragrance, freshly ground over them, and a pinch of salt, according to taste, and the whole stirred. The same process is equally applicable to French Beans, and also to that excellent mixture of French Beans and *flageolets*, so well known as *panachés*, so rarely served in this country. All these vegetables, when in excellent condition, are doubtless served at their best, *à l'Anglaise*, not only in relation to the palate, but also in view of the average digestion. But who does not know that the common mode, both in town and province throughout France, is to serve not only French Beans, but other vegetables, floating in rich, yellow, melted butter, rendering them for most English stomachs, at all events, hazardous, and to some repulsive.

To return to our *petits pois* as the type. When green Peas are a little hard, old, and tough, or a little coarse in flavour, and without sweetness, then it is that the French cook treats them with advantage. For such Peas as these, when no others are to be had—and it must be confessed that inferior Peas are far too commonly met with—by all means let them be served *à la Française*. This means stewing them gently, with a good proportion of butter, some sliced Onion, a little salt, stirring in a little flour and a small quantity of sugar. Some, exceptionally, add a little cream and yolk of egg. Another excellent French method, *à la Paysanne*, is to add first butter as before, salt and Onion; and then stew slowly in a fair quantity of stock, with Lettuces, finely sliced, some sugar, and a shred or two of Parsley, if desired. Almost any Peas may be rendered tender and appetising if thus treated.

Again, *haricots verts sautés au beurre* is a favourite mode of cooking them; but no superfluous butter should appear when they are served; the quantity allowed in which to toss them for a few minutes on a brisk fire, after boiling, should amount to no more, according to the rule, than a tenth part by weight of that of the vegetables themselves when dry.

The natural inference from all this is, that certain French methods are desirable, and their success is remarkable when the materials are inferior; but the English method is the simplest and best when the materials are—as they always should be—the best of their kind.—SIR HENRY THOMPSON, *Food and Feeding*.

How to Preserve Milk from Turning.—This is the time of year when milk is most difficult to keep. By adding a small pinch of soda, it very seldom turns. Salt may be used for the same purpose.—J. BAKER.

HOME PETS.

Treatment of Canaries.—In GARDENING ILLUSTRATED, April 24, there is an answer to a question as to the cause of feathers coming off canaries. It is a trouble of mine just now, and I shall be glad to know of what a diet consists that is nourishing and strengthening, yet not rich, so that I may try to cure this weakness in mine. Should canaries' food be changed occasionally or not? Is there anything that could be used to destroy any insect that troubles it, for it seems constantly annoyed with irritation of the skin? What can I do to make it sing? He sang very well a little time ago, but he has left off now again.—J. R. B.

Insects in Canary Cages.—If "L. R. F.," who inquires about small red insects infesting canaries and their cages, will pin a white pocket-handkerchief tightly over the cage at night, and examine it in the morning, he will be able to kill dozens every morning.—E. M. C.

Food for Dogs.—What is the best food for a Newfoundland dog? Are cows' buffs any injury to him, as he is very bad with worms just now?—NEWFOUNDLAND. [Good dog biscuits soaked is the best food, with a piece of raw meat or a bone occasionally. Cows' buffs always breed worms.]

Taming Love Birds.—The process for taming these, as other birds, is only time and patience. Take notice of them continually, and have them as close to your usual haunts as you can. They will gradually get accustomed to you, and ultimately will, without doubt, eat out of your hand and perch on your finger. If they are Australians their right name is Budgerigar, or Australian Grass parrakeet, of which I gave an account some time back in GARDENING. I shall be happy to answer any further questions on this interesting little species, which is the most popular of Australian parrakeets.—ADA.

Learning Parrots to Talk. — In answer to "E. A. E.," I should like to know how he has determined the age of his grey parrot. Some parrots begin to talk sooner than others, and naturally some are more talented than others and pick up sentences more quickly. Keep him in an adjoining room and do not let him see you whilst you are repeating words you wish him to learn, and repeat them as frequently as possible. Feed him with any kind of seed he prefers, also sop and fruit. Do not on any account forget to keep a constant supply of fresh water in his cage. The male grey parrot alone possess the power to whistle.—ADA.

Canaries in Newly-painted Cages.—Unless the paint is perfectly hard and dry, the birds will pick it, and therefore impair their constitution; but if perfectly dry and hard it will be quite safe to put the birds in. For my own part I prefer a plain wire cage with mahogany bottom—the sort known as waggon cages. They last longer and always look nice with a little care.—ADA.

COVENT GARDEN MARKET.

WHOLESALE PRICES.

Cut Flowers.—*Per dozen bunches.*—Anemone, 2s to 6s; Azalea, 4s to 9s; Cineraria, 6s to 12s; Ferns (various), 3s to 9s; Heliotrope, 6s; Lily of the Valley, 4s to 12s; Lilac, 2s to 8s; Mignonette, 4s to 9s; Narcissus, 3s to 12s; Pelargoniums (zonal), 3s to 6s; Pelargoniums (large flower), 6s to 12s; (double), 6s to 12s; (Rose-scented leaf), 6s; Spiræas, 6s to 12s; Tropæolums, 1s to 3s; Tulips, 4s to 9s; Violets (blue), 1s to 2s.—*Per dozen flowers.*—Abutilon, 4d to 6d; Arum Lilies, 3s; Tree Carnations, 1s 6d to 3s; Eucharis, 4s to 6s; Gardenias, 2s to 8s; Roses, 1s 6d to 6s.—*Per dozen sprays or trusses.*—Bouvardias, 1s 6d to 3s; Fuchsias, 2s to 4s; Primulas (double), 9d to 1s; Stephanotis, 2s 6d to 4s.

Plants in Pots.—*Per doz.*—Arum Lilies, 9s to 12s; Adiantum cuneatum (ordinary), 6s to 18s; Begonias (flowering), 6s to 12s; Begonias (fine-foliaged), 6s to 12s; Bouvardias, 12s to 18s; Cineraria, 4s to 12s; Daphne indica, 4s to 6s; Dracæna (green-leaved kinds), 12s to 30s; Euonymus, 4s to 12s; Euonymus (variegated), 6s to 18s; Ferns (greenhouse and stove, various), 6s to 18s; Ficus elastica, 18s to 60s; Fuchsias, 6s to 12s; Gardenias, 24s to 36s; Lily of the Valley, 12s to 24s; Mignonette, 6s to 9s; Nasturtium, 3s to 6s; Palms (small), 18s to 60s; Pelargoniums (fancy), 9s to 24s; Pelargoniums (scarlet), 4s to 9s; Pelargoniums (double), 6s to 12s; Roses (hybrid perpetual), 12s to 24s; Spiræa japonica, 6s to 18s; Selaginellas, 3s to 4s; Virginian Creepers, 6s.—*Per pair.*—Maiden-hair Ferns (large), 4s to 7s; Palms (large), 15s to 42s; Amaryllis, 1s 6d to 3s each.

Fruit.—Apples (culinary), per bushel and barrel, 9s to 30s; Cobs and Filberts, per 100 lb, 120s; Grapes (English hothouse), per lb, 2s to 6s; Lemons, per box, 30s to 35s; Oranges (various kinds), per 100, 8s to 16s; Pomeloes, per dozen, 3s to 6s; Pine-apples (St. Michaels), each, 5s to 15s; Pine-apples (English hothouse), per lb, 2s to 3s; Strawberries per lb, 1s 6d to 4s; Gooseberries per qt, 4d to 6d.

Vegetables.—*Per* 100.—Asparagus, 3s to 5s; French Beans, 9d to 1s. *Per dozen bunches.*—Carrots (outdoor), 4s to 5s; Watercress, 6d to 8d; Leeks, 1s 6d to 3s; Mint, 4s to 6s; Parsley, 4s; Turnips, 1s to 1s 9d; Radishes, 9d to 1s; Herbs, 2d to 6d. *Per doz. punnets.*—Cress, Mustard or small salad, 2s. *Per dozen.*—Cucumbers, 4s to 7s; Endive, 2s to 3s; Lettuce, 6d to 1s. *Per bundle.*—Horseradish, 3s to 6s. *Per lb.*—Shallots and Garlic, 6d; New Potatoes, 1d to 3d. Chervil, per punnet, 3d; Corn Salad, per half-sieve, 2s; Mushrooms, per pottle, 1s 3d to 1s 9d; Potatoes (general store, round kinds), per ton, 100s to 200s; Kidney, per ton, 120s to 180s; Parsnips, per tally, 5s to 7s; Rhubarb (per dozen bundles), 2s to 3s; Spinach, per half-bushel, 2s 6d; Tarragon, per bunch, 6d.

GARDENING

REGISTERED FOR TRANSMISSION ABROAD.

JAPANESE PRIMROSES.

THE annexed illustration of Japanese Primroses represents a race of hardy new forms of much beauty and variety. We are indebted to the late Mr. John Gould Veitch for the introduction of Primula cortusoides amœna, or P. Sieboldi as it has since been designated. This was followed by the white variety, the Lilac form known as lilacina (which is so distinct and altogether so unique in character, as to rank almost as a species), and the rose and white variety known as grandiflora, the inner or upper sepals of the petals of which is white, the reverse rose. Probably one or two of these are garden hybrids raised in this country. These fine forms were under cultivation in this country for a considerable time before new varieties were obtained from them. Probably this arose from the circumstance that P. amœna, which is most generally cultivated, rarely matures its seed. The other three are more free in this respect, especially the variety grandiflora. Now, however, there are some charming varieties in cultivation. Three of these are represented in the accompanying illustration: laciniata is a fine kind, remarkable for its large bold flowers, which are handsomely fringed on the edges and of a rich bright purplish-red colour; purea is a sort having large and finely, formed flowers of a bright mauve-purple-very distinct and handsome; and maxima, a greatly improved form of grandiflora, largely increased in size, purer in colour on the surface, and deeper on the reverse side. Mr. Dean, of Bedfont, Hounslow,

GROUP OF HARDY JAPANESE PRIMROSES—PRIMULA (SIEBOLDI) CORTUSOIDES AMŒNA.

from plants in whose nursery our illustration was made, has also raised many other varieties of scarcely less merit, but the foregoing will sufficiently illustrate their value. One chief merit possessed by these new Japan Primroses is, that they bloom early, coming in about the month of April, when flowering plants are not particularly plentiful; another is, that they are remarkably free bloomers, throwing up, as they do, successional flower-stems, and lasting a long time in perfection. For pot culture and cool greenhouse and window decoration they are unequalled at the time of the year just alluded to. Their cultivation, also, is comparatively easy. The best soil for them is light, free, rich material, consisting of fibry loam, leaf-mould, pulverised manure, and some grit to keep it open. When grown in pots the latter should be well drained, as the roots keep pretty near the surface; they are also impatient of excessive moisture, and when planted in the open ground (for the Japanese Primrose is a perfectly hardy plant), they should be in thoroughly drained soil, or in raised positions on rockwork. The roots creep just below the surface and form eyes, by means of which any one variety can be easily propagated. The Japanese Primrose is a herbaceous perennial, which loses its leaves in autumn and winter, when it goes to rest, and breaks up again early in spring. For growing in fancy earthenware pans or rustic vases, few plants surpass in usefulness these beautiful hardy Primulas. If old plants be divided every year, and a number of the pieces placed in large pans, they produce a mass of blossom that lasts, even in a sitting-room, for a considerable length of time; and in a cool, airy conservatory they of course last much longer. When cut the flowers soon shrivel, and they cannot, therefore, be recommended in that state; but no one possessing a cool house should be without a good display of these Primulas in early spring.

To Destroy Green Fly, Scale, or Thrips.—Two small wine-glasses of paraffin to 4 gals. of water; syringe the plant by most carefully keeping these two ingredients thoroughly mixed by working with the syringe deeply and briskly in the bucket several times before you use it on the plant. This mixing should be constantly repeated. Of course, like all other watering, it should be done after the sun has gone down. A burnt look, as of scorching, is the result if used too strong or without proper mixing; but most delicate plants may be thus treated without fear of harm.—E. L., *Lancaster*.

Snails and Tobacco-powder. — My Ferns were eaten all last summer by a small snail, so much so, indeed, that I could not get a frond above 2 in. high. I examined them night and morning, but could not get rid of the depredators. One day, however, I was dusting some small plants with Fowler's Tobacco-powder, and by chance I dropped some of it on a snail, which seemed to be killed by it almost instantly. I afterwards dusted half-a-dozen Maiden-hair Ferns with this powder, and with excellent results, for they shot up strongly, and have not been troubled with snails since; it might, therefore, have the same effect upon other plants.—G. W.

How I Make a Garden Pay.—My garden is 12 yds. long, 5 yds. wide. I have twelve frame-lights, which I fill with Celery in April, and I sell them all by the end of May at 4d. per score, about 4000 plants, besides 400 of the best, which I keep for my own use. When I have sold all the plants I take the frame work away and dig the ground over and level it down, then I plant my 400 Celery plants on it 7 in. apart, leaving a footpath every yard. When they are ready to earth up I tie them up nicely and put a 4-in. drain pipe over each one. When they are ready again for earthing up, I put another one over them and drive a stake 3 ft. long down by the side of each pipe, and tie a piece of matting round the stake and pipes to keep the wind from blowing them down, and they blanch beautifully. I have always fine Celery, and get 2d. and 3d. a stick, and it pays me very well, and when I have planted the Celery I make a lean-to greenhouse of my lights; six lights form the roof and three lights the front, two lights one end, one light and a door the other, and two triangle lights to fit ends under the roof. These lights are all screwed to a framework, and the crevices are puttied up, so that it is very nearly waterproof. I grow Pelagoniums, Balsams, Petunias, Cactus, Fuchsias, Musk, Ferns, Asters, Stocks, Roses, and Chrysanthemums, and they do very well. I get nothing but sun heat: that I get most of the day. Some amateurs will say they have no glass; I had none at first. I bought one light at first, and I soon bought another with the money I got in Celery planting.—T. J. A. B.

PLANTING OUT PLANTS RAISED IN POTS.

MANY plants that grow and ripen their produce in the open air are annually raised in pots under glass for the purpose of giving them an early start, and in the case of Tomatoes, Capsicums, &c., it is the custom to grow two or more plants in a pot, and when the proper time arrives for planting them out to do so with the balls entire. I am convinced, however, that wherever it is necessary, owing to want of space, to grow several plants in a pot during the nursing period, they should always be divided and the roots opened out when planted finally. As an illustration of what I mean, let us take a pot of Tomatoes, with say two plants in it, one on each side of the pot; it may appear at first sight that the plants would receive less check if turned out without breaking the ball than if it were broken through the middle and each plant planted singly, but there really is no comparison between the two modes of performing a very simple operation as regards the influence upon the future well-doing of the plants; and although I have instanced Tomatoes as furnishing a ready illustration, breaking the balls has perhaps less influence upon these than upon many other plants. I need not, I hope, say that I do not advocate any unnecessary mutilation of the roots, but the importance of giving them a proper direction outweighs any little inconvenience the plants may suffer from a root or two being injured. The fact is, when the soil is warm and moist, wounds heal with astounding rapidity, and new roots are formed in increased numbers without much check being given. I have watched the effect of this many times, and with various kinds of plants, and the advantage was always in favour of unlacing and disentangling the roots, even supposing a fibre or two were ruptured during the process. Whenever it is necessary to plant out anything that has become pot-bound, and it is not thought desirable to interfere with the ball, first make sure that the ball is thoroughly moist, and when planted, make the soil round it as firm as possible, leaving a slight cavity or basin when all is finished to concentrate the moisture over the ball. When plants are planted from pots with hard balls in freshly-turned-up soil the water drains away too rapidly, and the plants perish from lack of moisture, even though plenty may have been poured round them. And this is one of the greatest objections which I have to planting out pot-bound plants of any kind without disentangling their roots. The work and difficulty of keeping plants put out under such circumstances supplied with water in a dry soil are increased immensely, whereas if the roots be properly opened out in planting, and laid in fresh moist soil, one or two good waterings will be all that is necessary; if dry weather follow, mulch thinly or thickly, according to the size of the plants and the nature of the soil. I am not now thinking or speaking of plants that are constantly grown in pots, and have occasionally, as they increase in size, to be shifted on into larger pots. The two cases are not identical, for w there may be instances in which it may be sirable to reduce and open out the roots a l when subjected to fresh potting, in the maj of instances with plants in vigorous growth less the ball is broken up the better; but in growing plants in pots it is easy to make thin stratum of new soil between the ball the sides of the pot firm, so that instead of d ing off the water from the roots, it in re holds plenty of moisture in suspension, w gives the desired encouragement to the gro of the plant. F

VEGETABLES.

Gathering Peas.—If prolongation bearing be desired, Peas should not gathered indiscriminately, as is often d but the oldest of the pods should be remo as often as possible after they have bec fit for use, inasmuch as one pod allowed to old will weaken the bearing properties of plant more than many young ones; therefor it is better to gather and throw away than al them to remain on the plants after they are for use. In plucking the pods from the ha both hands should be used, so as not to br and damage the plants, picking only such p as are moderately well filled, for if young a old be gathered together they boil unequal Gathering for exhibition is also an operat that does not generally get the care bestow upon it which it deserves. When Peas wanted for exhibition they are not unfrequen gathered by a garden boy, or by some such p son, who takes no pains to gather them ca fully. Gathering Peas for exhibition requir comparatively speaking, as much care as cutti Grapes, but how seldom do they receive th attention. Only those who have some kno ledge of the matter should be allowed to gath Peas for such a purpose. A pair of scisso should be used to cut off the pods, cutti them all with the same length of stalk, ca being taken not to touch the pods, for fear rubbing off the bloom. The pods should al be as nearly as possible of the same length a equally well filled.

Mushroom Culture.—Any one in t possession of an outhouse or cellar, and who c command a temperature of from 47° to 50°, c at any time produce a good supply of Mus rooms. The best method is to procure (fre from the stable) as much short manure as necessary to make a bed from 14 in. to 18 i deep, and any size the house can convenient hold; throw the manure in a heap for a fe days until it becomes heated, and the great part of the moisture is thrown off; then spre it out for a day or two until it is dry and qui cool; after that put it again in a heap, and allo it to remain five or six days; it will then be f to make a bed, which must not be deeper tha the measurements just given. The bed requir to be beaten or trodden so as to make it firm and thus secure a more lasting heat and preve the temperature from rising too high at first As soon as the heat has risen and come down t about 74°, the bed is ready to receive the spaw —half a bushel will spawn a bed 8 ft. to 10 f square; it requires to be broken into sma pieces, about the size of a large Walnut, an placed in the manure; the bed should then b covered about 2 in. deep with good garden soi and well beaten down at the time when th spawn is put into the bed. A covering of ha or straw, if put on, and carefully taken off whe the Mushrooms appear, will materially haste their growth. If the above directions be care fully attended to, Mushrooms will begin t appear in about six weeks. After the bed ha been spawned, it should on no account b watered unless when very dry; a small quan tity of water, the same temperature as that o the bed, only to be given at a time. The wall and floor of the house may be damped in orde to maintain a moist temperature.—J.

Seakale.—Seakale can be grown eithe from pieces of the whipthong-like roots, cut i lengths of 6 in. or 8 in., which is the bes method, or from seed sown early in April. If by the latter method, the seeds are, as usual put in four or six together, in rows at interval of 1½ ft. apart in the rows, and a like distanc

row from row, they will require to be thinned to a single plant in each case, and the ground between should be kept well hoed, so as to destroy weeds. By this method, in good, deep, well-enriched soil, a portion of the plants will be strong enough for taking up to forceduring the coming winter, the weaker ones being allowed to remain for another year. The great advantage in growing Seakale from root cuttings is, that the plants have the start of those grown from seed, the greater part making strong roots the first summer. Nearly all that are allowed to stand a second season will throw up flowers, which must be cut away, or they completely prevent the plants making strong crowns; and under any treatment, these plants that have so thrown up a flower-stem are not so good as they otherwise would be; even when cut out as soon as it makes its appearance it causes the root to form several crowns, which are individually weaker, and not so good for forcing as a plant with a single strong crown. The old system of growing Seakale in rows 3 in. apart, the plant being the same distance asunder in the rows, and forcing it in the bed under pots made for the purpose and covered with leaves or other fermenting material, is extravagant in every way, both as regards the ground it occupies, the cost of pots, and the amount of labour involved. Forced in this way, it also often has an earthy taste. In the cultivation of this vegetable it should be remembered that it is a marine plant, and, like its congeners, is fond of moisture and manure of a silene character. Those who reside on the coast cannot do better than dig into the soil where it is grown plenty of rotten sea-weed; where this is not at hand a good dressing of refuse salt—4 oz. or 6 oz. to the square yard—applied through the growing season, but not so as absolutely to touch the plants, will be found highly beneficial to the crop.

Winter Spinach.—To afford constant pickings of this excellent vegetable throughout the winter, a greater breadth of it must be sown than most other things, as it does not grow fast enough to keep up the supply. The object should be to get the plants to that stage when they are about going to seed before they cease growing. At this stage they have their first good leaves, and they are in a condition to stand the winter, and are sure to produce plentifully next spring and onwards till the end of May, well overlapping the early spring sowings. To produce these results sowing should not be delayed beyond the middle of August, and it is often necessary to sow a fortnight earlier than that, but, like the winter Turnips, two sowings had better be made if the ground can be spared. Spinach likes a deep, rich, and rather light soil. Decayed vegetable litter or stable manure well rotted suits it well, and the manure should be deeply dug into the ground. Winter or prickly Spinach is the kind to sow. Eighteen inches between the drills is wide enough for the winter crop, and the seed must not be covered in more than 1 in. deep. When the seedlings are fairly up they should be thinned to 3 in. or 4 in. between the plants, and afterwards the surface of the ground should be stirred with the hoe. In picking for use the bottom and oldest leaves should be gathered, and the younger left to grow for successional pickings.

Fillbasket Peas.—After three years' experience I find no Peas to equal Fillbasket. The size of the pods (filled tightly as drums), the great weight of the crop, and, lastly, the excellent flavour, all render this Pea the best that could be grown for market purposes.—R. G. B.

Early Snowball Cauliflower.—This is one of the best of Cauliflowers. Its characteristics are earliness, dwarfness, and closeness of head, which is solid and white. March-raised plants of it begin to head by the middle of June. I have cut beautiful heads from plants in twelve weeks from seed sown early in July. When cooked it is soft and tender.—D.

Picking off Potato Blossoms.—This should only be done in the case of such kinds as bear fruit so abundantly as to weigh the haulm to the ground, and exhaust the plant. As a rule, however, not one-third of the kinds grown are free seeders. In order to test the effects of picking off the blossoms upon the future crop, a kind should be selected that is a large seed-producer.—A.

Supplanter Pea.—This is one of the best Peas I have tried for some years. It is dwarf in habit, vigorous in growth, and a heavy cropper, many of the pods containing nine Peas. I have just had a small dish cooked; they are of a beautiful dark green colour when boiled; and good in flavour. This Pea, from its dwarf, sturdy habit, will be found especially valuable for small gardens.—R. A.

Celery Fly.—The larvæ of the Celery fly (Tephrites onopordinis) in some seasons do much mischief to the Celery crops. When Celery is infested with the larvæ the leaves become blistered and turn yellow, and as the grubs are underneath the blisters they may be crushed between the finger and thumb. The grubs, when full grown, descend into the earth and remain in the chrysalis state until the following spring, when they give birth to the fly, which in due course deposits the eggs on the leaves. Therefore, to prevent the attack of the pest next year, leaves badly infested should be removed and burnt, to prevent the grubs attaining their full development. Mr. Rose, of St. George's Hill, Byfleet, having been for some years troubled with Celery fly, filled a 36-gallon water-barrow with sufficient water to dissolve two 1-lb. boxes of Gishurst Compound, mixing with it 1 lb. of Pooley's Tobacco Powder, and filling up the whole with boiling water, stirring all well together. The mixture, after being allowed to stand for some twenty-four hours, was used to water the affected Celery plants—a watering-can with a very fine rose being used for the purpose. The plants having been well saturated with this mixture were then examined, and the grubs which had burrowed into the leaves were all found to be dead. The crop, too, seemed to be greatly improved, the mixture having evidently acted not only as an insecticide, but as a fertiliser. About three weeks after he repeated the same treatment with another crop with precisely the same results.

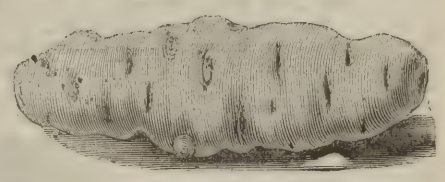
The Best Receipt for Making a Copying Machine.—Gelatine glue, 2½ oz., water, 5 oz.; let the above soak together for twelve hours, then add glycerine, 5¼ oz. fluid, carbolic acid, minims x. Dissolve glue in water at a gentle heat in a jar in pan of water, then add the other ingredients; stir, and strain through muslin and let it stand for about twelve hours. Ink.—A penny packet of Crawshaw's violet dye in ½ oz. of water, and plenty of moist sugar. Before using rub gently with a sponge and cold water, taking the wet off by placing a clean sheet of blotting-paper on the surface.—Subscriber.

Cats and Nemophila insignis.—Pour a little hot water over twopennyworth of bitter aloes, and then fill up with cold water to about two quarts. Let it stand all night, and next evening water the leaves of the Nemophila with it, and the cats will not touch it. The same bitter aloes will last through many waterings until they melt away. The smell is not strong enough to be noticed by us, but the cats dislike it.—E. R.

Sawdust in Gardens.—In reply to several queries, and for the benefit of those interested, I will just state my own experience in connection with sawdust in the garden. Two years ago I entered upon possession of my present house and garden (new), which latter was like a turnpike road, owing to the builders running over it. I had it well dug and manured, but did little or no good during the summer of 1879, for after every shower of rain, and being so much clay, it was set down quite hard again, and nothing would grow. That winter I had it well turned over, and all the ashes from the house sifted and turned in with plenty of manure. Last year it was a trifle better, but still bad. I asked this same question, and one or two correspondents wrote against using sawdust; I, however, last autumn determined to try it. Accordingly I obtained a few sacks, which I shook thickly all over the ground, more manure, more ashes, about a bushel of soot, a quantity of salt, and some fresh-slaked lime—this was all worked over three or four times during the winter. I have planted it this spring with Scarlet Runners, Dwarf Beans, Turnips, Lettuces, Radishes, and Onions, besides round the borders all sorts of flower seeds, and everything is doing well. The Beans have come up with only three or four failures where in previous years they could not break through the ground. I do not know that there would be any manurial properties in sawdust, but used as I have described I have turned a hard clay garden into a rich, light, and flourishing one. This would not be desirable for growing everything, but where a light soil is required I can recommend sawdust, if used in combination with the other ingredients. I may just mention that my garden is about the usual London size, viz., about 40 ft. long and 18 ft. wide; locality, Clapham.—Ferndale.

Horticultural Shows.—Your correspondent "Tremadoc" will find, as far as Strawberries are concerned, that fruit 1 oz. each will make a fine show sample, but then something depends upon sort and colour, and size alone don't make up for the lack of these. Even twenty fruits to the pound of President or Sir Joseph Paxton, the best show sorts, and handsome and of good colour, will be hard to beat. Excellence does not always depend upon weight. If it were so, the scales and not the eyes would be the most exact judges.—A. D.

The Vitelotte Potato.—This is the curious looking, sausage-shaped, little reddish Potato which comes to Covent Garden from



The Vitelotte Potato.

France. It is, we believe, used in preference to all others for Potato salads. It may often be seen exposed in the Central Row.

FRUIT.

HOW TO GROW STRAWBERRIES.

Soil.—In the cultivation of Strawberries the soil is of much importance. The best Strawberry soil is a good sound loam, and if rather unctious so much the better. A poor light soil is quite unfit for Strawberries, but much may be done by deep digging and liberal supplies of manure. A light soil should be trenched fully 2 ft. deep, and plenty of manure should be placed at the bottom of the trench. For a moderately stiff soil, two good spits, or about 20 in., will be found ample. In either case, the soil should be made rich with manure; and at the time of planting ample space should be given for future development.

Selection of Runners.—This is also an important consideration. Those only should be employed that are stout and healthy, with a good round, plump bud in the centre; and they must be from fruit-bearing plants. When runners are taken at random from unfruitful plants, the progeny generally proves unfruitful also. It is of the utmost advantage, in order to obtain the runners quick, and to get them soon into their fruiting quarters, that they be layered in small pots about 4 in. or 5 in. in diameter, filled with rich loamy soil, and mixed with a little rotten dung. While they remain in the pots they must not be allowed to suffer from want of water. They will make rapid progress in this rich compost; as soon as they are fairly rooted they can be cut away from the parent plants, and, as soon as convenient afterwards, they should be finally planted out before the pots become matted with roots. Such plants in dry weather succeed much better than pieces of runners without roots, those in pots commencing to grow at once, while the others dry up. Last autumn I formed a plantation with plants that had been layered in pots, with the exception of one row that came from a neighbour that had not been layered. Those that had been prepared by laying in pots are six times as large as those just alluded to, and are bearing six times as much fruit.

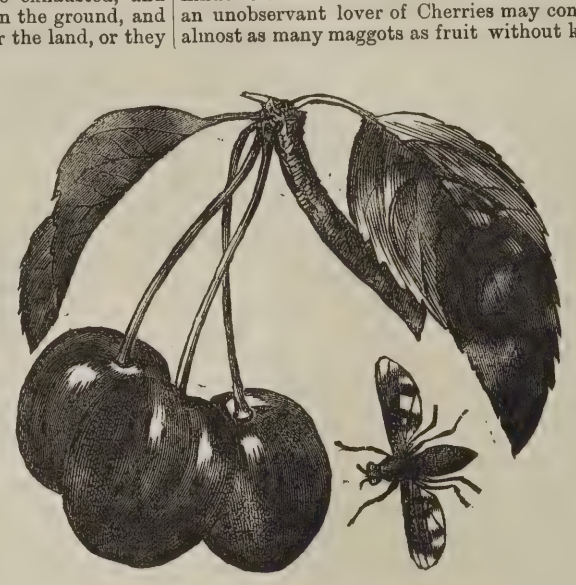
Planting.—In planting I perhaps give more space than many people think proper, but it has always been a first principle with me to

give crops ample room for development, and I rarely ever find any plant ungrateful for such liberality. The planting requires great care, for on this much of the ultimate success depends. I would here advise, if the soil be very light, that it be made firm before planting. When convenient, a portion of clay should be added to it, which will much improve the condition of the plants. If the ground be tolerably stiff this will be unnecessary. In planting, take care to make the ground firm about the roots. There is scarcely any soil so poor but what may be made to grow good Strawberries if properly managed. With regard to distance, we allow them, on an average, 27 in. or 30 in. from row to row, and about 2 ft. apart in the rows. I have known some, who have wished to make the most of their land, plant 1 ft. apart in the rows, and, after the first crop, destroy every alternate plant. Others I have known to have planted a row of Coleworts between each row, and to have pulled them up by the roots early in spring, leaving the whole space to the Strawberries. I never allow a bed to remain longer than three years before it is destroyed. Good fruit is obtained the first year after planting; the crop may be a little heavier the second year, but the fruit will be finer the first year. The third year the crop will be good, but the fruit will not be so fine as it was either the first or second; and, after it is gathered, the bearing powers of the plants will be exhausted, and they should either be burnt on the ground, and the ashes carefully spread over the land, or they should at once be dug in, thus restoring to the soil much of the matter which has been absorbed by the plants in their growth, and the absence of which has lessened fertility in a corresponding degree.

Varieties.—Where Alpine Strawberries are grown they may be treated as annuals, the old plants being destroyed every spring; they will then yield a good crop of fruit when others have done bearing. Eclipse with us is a great favourite, being a heavy cropper, of average flavour, and an excellent variety for pot culture. Sir J. Paxton is a handsome early variety, the flesh of which is very solid. Its flavour is very good, it forces well, is a very free grower, and quite hardy. Its appearance, which perhaps surpasses that of all others, renders it valuable for dessert. It is of a rich bright glossy colour, and should be in every collection. Dr. Hogg is very much like the British Queen, from which it was raised. It is, however, much finer, a better grower, has a better constitution, and has established itself as a general favourite. I am now gathering fruit from this variety which will average nearly 2 oz. each. It is one of the sweetest Strawberries grown. Cockscomb is a very fine and handsome variety when it succeeds, and is, where it is known, a great favourite. Vicomtesse Héricart de Thury is a good kind; the skin is deep scarlet in colour, the flesh firm, solid, and highly flavoured. The plant is vigorous and nearly as productive as Eclipse, though the berries are not quite so large. It continues a long time in bearing. The foliage resembles that of the old Keen's Seedling. It is a valuable variety for general cultivation. Amateur is a fine conical-shaped berry, with a rather acid flavour, but a heavy cropper. These kinds are what I have grown this season, and are now in full bearing.

Mulching.—For the purpose of keeping the fruit clean I use litter, which, if it does not meet the views of some fastidious people, has the advantage of thoroughly answering this purpose. On dry, gravelly soils little good can be accomplished in a dry hot season without plenty of water. This may be considered the life and soul of the Strawberry. With a hot sun and plenty of moisture, the fruit may be brought to great perfection; without them, it languishes. It is, therefore, obvious that a good supply of water is a necessary adjunct to every Strawberry garden. As soon as the blossoms begin to expand, the water should be given freely; and if, before the plants go out of bloom, they can be given a good soaking of manure water, it will almost double the weight of the crop. I consider the application of manure water to Strawberries, while they are in bloom, the secret of success. Gardeners of the old school used to allot certain quarters to the growth of certain crops, and more especially those of Strawberries; but I would particularly advise that such a practice should be abandoned, and a fresh situation for every succeeding plantation provided. When the ground has been occupied for several years with the same crop, it becomes exhausted; and my own experience has convinced me that Strawberries form no exception to this rule. R. E.

The Cherry Fly.—Some little two-winged flies, having their transparent wings elegantly blotched or marked like those of the fly figured in the accompanying wood-cut, may often be seen in orchards and gardens. The insect here figured is one of them. It feeds on the fruit of the Cherry; not, indeed, of every kind of Cherry, for it eschews all those which are acid or acidulous, but on the fruit of the sweet soft kinds it is in some seasons so abundant that an unobservant lover of Cherries may consume almost as many maggots as fruit without knowing it. The fly is common in the month of May in those districts where Cherries are much grown. It is black, with a yellow head, and its transparent wings are obscured by four transverse bands. The female fly lays one egg on each fruit. As soon as the maggot comes outof the egg it makes haste to bury itself in the Cherry, in order to consume the pulp. It is elongate, horn-shaped or conical, and white, but when writhing in the purplish or rosy pulp, and full of its juice, it partakes also of its colour. Generally speaking, its presence does not prevent the fruit increasing in size and arriving at maturity, although sometimes the Cherry drops a little before its perfect development. When the maggot is full grown it comes out of the Cherry and buries itself in the earth, where it passes into the pupa, in which state it remains until the month of May of the following year, when it comes out as the perfect insect.—A. M.



A Cherry Destroyer.

A Neglected Hardy Fruit.—It is only of late years that the Currant has received the attention from fruit growers that its quality and character justly deserve as a table or dessert fruit. A few neglected bushes of the old Red Dutch hid away in the garden yielded from year to year the scanty supply for making jelly, and occasionally table use. Since the more general introduction of the Cherry, La Versaillaise, and White Grape Currants, the culture and treatment of this fruit have been noticeably improved in every direction. The selfsame old Red Dutch, under high culture and annual prunings, yields large crops of superior quality of fruit; in fact, equals in point of pr fit any of the newer and larger sorts. It wi be found a saving of time and expense to pra tise summer pruning with the Currant. A lar part of the young shoots may be pulled out the older bushes early in July while the wood succulent and soft, and those to remain may shortened in by pinching with the thumb a finger. A bearing bush should be kept open a spreading; when this surplus young wood is r moved in July, the bearing parts a strengthened, and more and larger fruit is pr duced on the same surface the following yea —T.

Mildew on Vines.—I cured my Vines this troublesome pest when I was growing the same time the house full of plants, so wi the constant watering of the plants it was easy matter. In the first place, as soon as I sa mildew appear, I took 2 oz. of flour sulphur and put it in four gallons of water a well syringed the Vines with it. The followi week I syringed again, afterwards kept t Grapes as dry as possible, and then, with common pepper-box, I well dusted the bunch with the dry sulphur, and continued to do so long as I saw any mildew; but a long time b fore the Grapes coloured it had all disappeare and then I got a dusting-brush, such as is us in the drawing-room for dusting ornaments, a with it I thoroughly dusted all the sulphur the Grapes. I have been cutting this l three weeks, and not a spot of mildew can found on the berries.—C. DOE.

Thinning Grapes.—Grape-growers are agreed upon one point, namely, that the soo Grapes are thinned the better. If done so after the Vines are out of flower, the opera ought to be practically acquainted with t habits and characteristics of the different var ties, for if he be not, he will be unable at so ea a stage to distinguish between berries that fertilised and those that are not. To produc bunch of Grapes well formed in all points is, the case of some varieties, a difficult matter; others we have little more to do than to ass Nature. Every skilful Grape-grower kno that what is termed a well-finished bunch Grapes cannot be produced by chance or h hazard; it is much easier to grow large bunc than to finish them well. It is therefore har possible to over-estimate the value of ea thinning; the Vine is relieved of a needl drain upon it, and there is no need to distu the fruit in order that the operator may get the berries which he wishes to remove. evil belonging to thinning Grapes when in advanced stage of growth is, that if the po of the scissors gets moist with sap from fruit-stalks, and the acid touches the fruit, produces a spot that the bloom will ne cover, although the berries may be in ev other respect perfect. The hair-like stre that we sometimes see upon otherwise beauti black Grapes are often produced by the po of the scissors at an early stage of growth. is a well-known fact that the bloom of Gra roughly handled when growing never becor perfect.—J. T.

Hardy Annuals.—Annuals are loo upon as common flowers, but at best they but imperfectly known. If evidence of were needed, it could be found in lists of ki frequently recommended for cultivation, wh invariably include some that are scarcely wo growing, and omit others that are really valua Provided the soil be warm and light and situation dry, there are some annuals should be sown in autumn, as, unless the wi prove wet and severe, they root better, mak more profuse growth, and flower earlier tha sown in spring. Among those which may sown in autumn may be mentioned Nemophi Sweet Peas, Candytufts, Eschscholtzias, Sw Alyssum, Virginian Stock, and Limnan Douglasi and grandiflora. The following the names of some of the choicer kinds of ha annuals that well deserve a place in gard viz., Calendula pluvialis, a kind with la star-like, white flowers, having a dark cen dwarf and very free; C. Pongei, a double f of this, lasting a long time in bloom, and like a white Chrysanthemum, but lacking perfect arrangement of the petals; Centa

(Cyanus) depressa, a sort with large, showy, rich, pale blue flowers, very striking at this season of the year, and most useful to cut from; Calendrinia speciosa, pretty rose; Collinsia bicolor; C. multicolor, a purple form of C. bicolor, and very good; Gilia laciniata, purplish-mauve, the flowers borne in dense clusters, a capital plant to cut from; G. achilleæfolia, purple, very good; G. tricolor, effective; Helenium Douglasi, silvery foliage, large green flowers with orange centre, very effective; Linaria bipartita, white, margined with purple, very pretty, and remarkably free, growing from 12 in. to 15 in. in height; L. spartea, very bright orange and yellow, highly effective; Leptosiphon androsaceus in variety, which includes several very pretty colours, such as white, cream, lemon, rose and purple; Lasthenia californica, one of the most effective of the yellow-flowering spring annuals, the flowers golden yellow with an orange centre, very dwarf, free and effective, especially at a distance; Loasa tricolor, orange and red, dwarf, bushy growth, very good; Nemophila insignis; N. maculata, the flowers white spotted with purple, large and showy; N. discoidalis and its varieties are interesting, but they lack the fine bold form of N. insignis; Œnothera Bistorta Veitchi, with pure yellow flowers on a dwarf growth, very free and effective; Schizanthus pinnatus, very handsome, with dark blotches on the upper petals; S. gracilis, a slender growing form, the flowers pale purple with dark markings; S. pinnatus tigrioides, the upper segments flaked black on a golden ground, very pretty indeed; Silene rubella, dark magenta, very pretty; S. Pseudo-Atocion, bright pinkish rose, very bright and effective; and S. Saponaria, a very attractive pink, like a large-flowered Saponaria calabrica; Veronica syriaca, pretty bright blue, might be very effectively grown in pots for spring work; and the white and red Valerians, both of which are valuable to cut from just now. This may appear a long list, but it is a select one, and it represents the very best annuals in bloom in the middle of June.

Annuals for Pot Culture.—As annuals are, as a rule, better suited to the requirements of persons possessing only small gardens and little glass accommodation than more costly plants, the following selection from the large collection now being exhibited by Messrs. Carter & Co. at the Royal Botanic Gardens, Regent's Park, may be of some value. The plants in question are grown in 5-in. pots, and we think them much better this year than we have seen them in previous years. The majority of these annuals are best sown in autumn and protected from rough weather in winter. In spring they may be plunged in ashes in an open situation until they come into bloom, when they may be moved to the greenhouse or window. The following struck us as being the most effective and most easily grown: Collinsia bicolor (purple and white), C. alba (white, fine); Veronica syriaca, a little Lobelia-like plant, very pretty; Silene compacta, very dwarf, flowers large, and of a deep pink colour; Sphenogyne speciosa, bright yellow, very showy; Saponaria calabrica, rosy-pink; Nycterinia selaginoides, very pretty, varied coloured blossoms; Kaulfussia amelloides, dark blue and light blue; Gilia rosea splendens, rose; Linum grandiflorum, brilliant scarlet (fine); Leptosiphon roseus, one of the prettiest of all annuals; Nemophila insignis, blue and white; Nemophila discoidalis, very elegant, black with white edges; Mimulus cupreus, copper colour; Linaria bipartita splendens.

Prolonging the Bloom of Pansies.—Pansies are still among the most attractive flowers of our gardens. When they become somewhat tall, and, as not unfrequently happens in the south, infested with insects, it is a good plan to cut them close down; when this is done, especially if they get a good watering where needed, they soon push up strong clean shoots and flower again abundantly. In some southern gardens this practice is repeated with success several times during the season.—V.

The Pampas Grass.—The finest example of this I have seen was in Staffordshire. It was growing on a well-drained lawn; but holes 8 ft. deep, and filled with loam and cow manure, had been prepared for each plant. One plant, three years planted, was of immense circumference, the leaves unusually broad, long, and erect, and bore about two dozen flower-spikes, which stood nearly 12 ft. high. This was simply due to high culture in a climate not unfavourable to it, and no doubt the same could be accomplished in the neighbourhood of London. The plant requires a deep rich soil and abundance of moisture in summer, but a thoroughly dry bottom in winter. Under such conditions, I have seen it stand without any protection in winter in Scotland and flower annually.—S.

TALL BELLFLOWERS.

The Tall Campanula (Platycodon grandiflorum) is a thoroughly good herbaceous plant perfectly hardy in light dry soils, but most impatient—as, indeed, is P. autumnale—of damp and undrained situations, where its thick, fleshy roots are sure to decay—sometimes from below upwards, but more generally from above downwards, rotting off just at the neck. As the specific name would indicate, the flowers of P. grandiflorum are much larger than those of

The Tall Autumn Bellflower (Platycodon autumnale).

its closely-allied species P. autumnale, being as much as 2 in. to 3 in. across, of a deep blue colour, with a slightly slaty shade therein. They are produced in clusters at the summit of each of the branches, which proceed from the old root-stock, rising to a height of about 18 in., and being very slender at the base. If neglected in the matter of supports in their early stage of growth, they are sure to fall to the ground, thus giving the plant, however beautiful its blossoms may be, an untidy appearance. This a little forethought will readily obviate; but, be it noted, if such a result occurs from early neglect it is almost impossible to remedy it when the flowers are nearly developed, as branch after branch will break away, if made to assume the usually erect position, in the process of tying. When down, it will be better to leave them as they are, allowing the bloom to compensate, by its beauty, for any untidy appearance that the plant may present, merely taking the precaution to peg down the branches, else the sportive winds may whisk them round, and effect their total dislocation from the parent stock. Possibly the best position for such a plant would be overhanging a rock ledge in a sunny corner of the rock-garden, where a negligent character of growth would be in keeping with its situation, and its flowers, produced on a level with the eye, would be shown to great advantage. Like most of the Campanulas, it has a tendency to sport in colour, and to revert from blue to white through various modifications. Equally pretty and acceptable as a garden plant is the white variety, though it is by no means so frequently met with as the blue type.

Platycodon autumnale comes from China and Japan. Compared with P. grandiflorum, it is both taller and more robust in growth, attaining a height of 3 ft. under favourable circumstances; its leaves are narrower, but more densely arranged than those of P. grandiflorum; and its flowers, though smaller in size, are produced in greater quantities and are pretty evenly distributed along the upper half of the stems. This arrangement is shown in the accompanying representation of the plant. From its taller stature, and also the fact that its young shoots are far more woody and vigorous in their growth than those of P. grandiflorum, its true position should be in the second or third rank of the herbaceous border. Besides a white variety, we find in this species a tendency to become semi-double, by a sort of "hose-in-hose" re-duplication of the corolla, similar to what occurs in many of our Campanulas. There are one or two specialities in the matter of cultivation that apply equally to both species. First, as regards removal: if a strong well-established plant is to be transplanted, let it be done in the month of May, when growth has commenced; the thick fleshy roots are sure to be more or less damaged in the process, and Nature must be in an active state to repair such damage. If this be done during the winter, when the plant's energies are dormant, decay from the multilated parts of the root upwards is sure to take place, and the strong probability is that the entire root-stock will become affected. The spade must be looked upon as a decidedly warlike implement to use among these plants; one unlucky thrust through their brittle crowns and they, the plants, are gone for ever. Indeed, the less such an implement is used in borders devoted to the culture of herbaceous plants the better. In cutting down the stems in autumn it is usual, with a view to neatness, to cut close to the crown. This, however, as Nature herself teaches us, is not at all times a good practice, and this especially applies to the Platycodons; if cut close, their hollow stems form conducting pipes to carry water into the very heart of the plant, and the result is decay from above downwards. The same caution is applicable to many other plants besides Platycodons. As regards propagation, the best mode is that of raising seedlings. Unfortunately, our climate is ill-adapted to the maturation of seeds in general, and especially so with regard to Platycodons; they, however, seed freely on the Continent, and from that source a supply can readily be obtained. The young shoots, taken off when about 3 in. long, in spring will strike if placed in a gentle bottom-heat, but not freely. I have seen it stated that the fleshy roots, cut into lengths and placed under similar treatment, will grow, but my experience only realise the development of buds at the upper end, accompanied by decay in place of root-development below, and the final result was failure. To those who possess strong vigorous plants of either species, I would say: Don't disturb them, even at the pressing wish of your best friend, who may covet a portion thereof; rather get a packet of seed, and exercise all the patience you may happen to possess, and the result will be more satisfactory both to yourself and your friend than if your well-established plants had been mutilated in an attempt at division.—J. N.

IMPROVED FLOWER GARDENING.

I SEND a list of the plants which bloom year by year in my mixed border, some 90 ft. in length and 3 ft. 3 in. in width; a brick wall at the back, aspect east. They have cost me little or nothing. I beg a piece of a plant, or a few seeds, in exchange for any I may have, from the gardens of various friends or cottagers, and from time to time divide the plants. Occasionally I buy 6d. of road scrapings, with which I mulch various plants, as recommended in GARDENING ILLUSTRATED,

My entire back garden is about 90 ft. by 30 ft. I have in it, besides the mixed border, a small Grass plot, a round flower bed, a wild flower bed, six rows of Strawberries, from which I gather on an average some three dishes daily for a month; some Red Currant trees border the Strawberries, and from them I have a good supply of fruit; six Gooseberry trees amongst the Strawberries supply me with tarts for six weeks, and some ripen; a Rose bed, containing some thirty different Roses; a piece of ground for various herbs, with a border of black Currants, very free bearers; also a border of white Currants, which yield well; a row of Raspberries, great bearers; a mixed flower bed; a hermitage, covered with Hops and various sweet-scented climbers, shaded by a Sycamore tree; and lastly, a rockery—some twenty varieties of Ferns and various Stonecrops and wild flowers in it.

When I took possession of the garden its crop was Groundsel and Cabbages. My aim was to have as much variety as I could get in so small a space, and all who see the result say I have succeeded.

I omitted to say a Laurel hedge borders my garden on one side, and at the bottom and on the wall which backs the mixed border I have fruit trees, various Roses and climbers, and where the wall has bare spots I have stuck in Ferns and Stonecrops, creepers, Wallflowers, and such like. There is one path the length of the garden and four across it.

January.—Winter Rose (large and smaller), winter Aconite.

February.—Snowdrop, Bulbocodium vernum, Scilla bifolia, Crocus (yellow), Crocus (mauve).

March.—Yellow Primrose, mauve Primrose (double), white Violet, purple Violet, Czar Violet, single Daffodil, double Daffodil, Lungwort, white Arabis.

April.—Scarlet Daisy, white Daisy, purple Aubrietia, blue Forget-me-not, white Forget-me-not, Wallflowers (various colours), yellow single Hyacinth, pink Hyacinth (double), Omphalodes verna, Cowslip, purple Crocus, white Crocus, single Jonquil, double Jonquil, pink Fumitory, red Primrose, scarlet Anemone, Wood Sorrel, Adonis vernalis, mealy-leaved Polyanthus, yellow Alyssum, purple Pansy, Sweet Woodruff, Fritillary (purplish), quilled Daisy (very large), crimson Daisy, Speedwell, garden Bluebell, maroon Pansy, Narcissus, single Wood Anemone, double Wood Anemone.

May.—Brompton Stock, Tulips (various colours), Dielytra, Bladder Campion, Cowslip, double white Primrose, Globe-flower, Starch Grape Hyacinth, Fair Maids of France, London Pride, Lily of the Valley, Perennial Iberis, Bluebottle, Solomon's Seal, purple Lupin, Virginian Stock.

June.—Yellow Pansy, variegated Pansies (various), Viola (pale blue), Cerastium, China Rose (pink), Gloire de Dijon Rose, white Clematis (single), crimson Pæony, Musk, Brier Roses (yellow, white, and pink), Garlic (yellow), Deutzia, Spiræa japonica, Thalictrum, white Pink, pale mauve Pink, Turk's-cap Lily (yellow), orange Lily, China Rose (crimson), Eschscholtzia (yellow), Candytuft (white, purple), Monk's-hood, Agrostemma (pink), scarlet Lychnis, chocolate-blotched Pink, Nemophila insignis, Spiræa (white of two sorts), purple Crane's-bill, double white Primrose, Polyanthus (various shades), purple Iris (delicate pale narrow leaves), Star of Bethlehem, half Moss Rose, Céline Forestier, Roses Annie Wood and Général Jacqueminot, pink Pyrethrum, crimson Geum, yellow Geum, white Crane's-bill.

July.—Eccremocarpus scaber, Ivy-leaved Toad-flax, yellow Stonecrop, white Pyrethrum, Day Lily, Turk's-cap Lily (mottled), white Lily, Sweet Pea, Borage, Mignonette, Sweet William (various shades), blue Campanula, Poppy, Lythrum, Paul Verdier Rose, blush Rose, white Rose (common), Lamb's-ear, various Nasturtiums, Bergamot, Marigold, Clematis integrifolia, Everlasting Pea (large purple flower), Phloxes (various shades), Clove Pink, pink Carnation, Sweet Brier, Japanese Honeysuckle, common Honeysuckle, Lavender.

August, September, and October.—Many of the above flowers remain in bloom, and many bloom a second time.—MARK.

Amateurs' Flower Show.—A flower show is to be held on July 28—29 in the schoolroom adjoining the Wesleyan Chapel, Liverpool Road, London. There are vacant spaces for competitors. Any amateur wishing to exhibit any flowers may do so by first consulting Mr. Priest (hon. sec.) for particulars on any Wednesday evening on or before July 7.—S. C. M.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

July 5.—Potting Celosias, Primulas, and herbaceous Calceolarias; shifting Amarantus salicifolius, and potting off young Balsams; sowing Bath Cos Lettuce, Digswell Prize, and dwarf green Curled Endive and Spinach; earthing up Cucumbers and French Beans; planting out Sunflowers; sowing Cucumbers for late crops; potting Tree Carnations; also a large batch of Roses in good strong loam; planting out Autumn Giant and Self-protecting Broccoli; thinning Turnips and Early Horn Carrots; sticking Peas and getting them earthed up; pulling up all blind-hearted Cauliflowers and Broccoli, and filling up their places with good strong plants.

July 6.—Planting out a pit with Tender and True Cucumbers; training out and pegging down bedding plants; staking and tying in plants on borders, and clearing away decayed leaves and flowers; taking the nets off Strawberries and putting them on Currants; weeding amongst Leeks and giving them a little earthing up; potting Bouvardias; sowing Nonpareil and Advancer Peas, Cabbages, and Early Horn Carrots; putting in Pelargonium cuttings; clipping shrubs, and giving Peach trees in pots a top-dressing of manure; hoeing among fruit bushes and putting Epacrises in cold pits.

July 7.—Digging up a large piece of Gloucester Kidney Potatoes and placing them out thinly in the sun to ripen well for seed next season; watering Celery and Cardoons; also Lettuce and Endive beds; drawing drills for Spinach and well watering them previous to sowing; nailing and tying in all the leading shoots of fruit trees on walls and pinching back all the breast wood; potting up a large batch of President and Sir Charles Napier Strawberry runners for forcing; sowing Six-week Turnips, Long-podded Negro, and Sir Joseph Paxton French Beans; also a late crop of Broad Beans; putting in cuttings of Crassula coccinea; watering and mulching Peach trees and training conservatory creepers; placing Camellias in Peach house where they can be shaded a little.

July 8.—Sowing Ne Plus Ultra Peas; planting Ten-week Stocks; salting Asparagus and Carrot beds; nailing up Tomatoes and outdoor Figs and Vines, and watering Scarlet Runners with guano water; sowing Sweet Basil and Chervil; potting on Campanula pyramidalis; also young Cyclamens; taking up Shallots and Potato Onions and laying them out in the sun to ripen; gathering Camomile flowers, also Sweet Basil, Horehound, and other herbs for drying; weeding and cleaning all Box edgings in kitchen garden; hoeing and weeding amongst Peas; nailing and tying in Roses on walls and picking off all dead flowers; watering all newly-planted Broccoli, Cauliflowers, and Tomatoes, and renovating linings round manure frames.

July 9.—Sowing a border of Early Horn Carrots and a box of Intermediate Stocks; planting Asters; putting in cuttings of Poinsettias; clearing land of early Peas, and digging it for late Cauliflowers, also preparing land on which to plant Endive; watering French Beans with guano; leaving night air on Vineries and Peach houses in which fruit is ripening; sowing Lettuces and Endive; potting-up Strawberry runners for forcing; nailing in Tomatoes and closely stopping them; tying up Dahlias and thinning them out where growing too thickly; earthing up Celery when the soil is dry and in workable condition.

July 10.—Potting off herbaceous Calceolarias; layering Carnations; looking over Cucumbers and Melons, and stopping them where required; weeding and picking over carpet-bedding plants; cutting up turf and putting it in water to soak for layering Strawberries on; watering Celery and flower borders, and rolling down all gravel and Grass that require it; potting off seedling Musk plants, Coleus cuttings, and White Pinks; sowing Mignonette in pots for autumn flowering, also Prickly Spinach and Radishes; planting Cauliflowers for late supply, and pricking out Wallflowers; clipping hedges and cutting Laurels; pinching and pegging down plants in flower garden, and picking off all decayed flowers and leaves; sowing Turnips, having previously watered the drills into which a little guano has been placed; planting Neapolitan Cabbage Lettuce, Sweet Basil, and Marjoram; putting in cuttings of Kalosanthes, clipping Arabis and Cerastium edgings, and digging land for late French Beans.

Glasshouses.

Tuberous Begonias.—In addition to the immense quantity of seedlings raised by those who grow them in that way there are a large number of fine named varieties now becoming plentiful, varying very much in their general character from the long, pointed-flowered, drooping forms to those of the very broad-petalled kinds, the flowers of which in some cases are almost erect. The former are generally much the more profuse in flowering, and are more elegant. Taste in this, as in other matters, may vary, but there is no reason why a portion of each should not be grown. They are a very acceptable addition to greenhouse subjects, not only from the variety of bright as well as delicate colours which they afford, but also from their distinct habit and long continuance in bloom. But although their natural habit is to keep on flowering for months, their ability to make a full display for the greatest length of time of which they admit depends to a considerable extent upon sufficient nutriment at the roots. The pots in all cases must be large enough, proportionate to the size of the plants. I mention this particularly, as, through their free disposition to flower, beginning to bloom, as they do, almost as soon as the young plants are fairly in growth, it is not an unusual occurrence to see them allowed to remain in the comparatively small pots they begin to flower in, and so get completely exhausted before the season is over; but before they suffer in this manner they should be moved into others of a larger size. If the operation is carefully done without much disturbance of the roots, they will receive little or no check, in which way they may be grown to a large size where required. Clear, weak manure water will also assist them, but will not make up the deficiency where the quantity of soil available for the roots is much too small. Where any particular variety is required to be increased, this can be done by cuttings, as they strike freely, but the tubers formed do not in all cases grow. Some growers prefer to increase them by leaf cuttings, the tubers from which are smaller, but more disposed to go on afterwards. To keep them moderately bushy a good light position is necessary, as the shoots keep on extending as they bloom, and there is usually a reluctance to pinch out the points with a view to make them break back, for by so doing the flowers, to a certain extent, are for a time reduced in quantity.

Epiphyllum truncatum.—Through the amount of neglect that these plants will bear without causing their destruction, they sometimes receive so little attention, as to make a great deal of difference at the flowering time. The position that will suit them best, if such can be spared, is an empty pit with the lights well tilted, so that they can get plenty of air, in which way they will be neither liable to get saturated with wet by thunderstorms, nor to be blown over and broken by the wind when out-of-doors; but where a place of this description is not available they can be set out under a south wall, tying those that are got big and heavy to sticks to keep them from being blown about.

Large-flowered Pelargoniums.—Those that bloomed the earliest should, as their flowers get over, be placed out-of-doors in the full sun to ripen their growth previous to heading back. It is much better not to delay this operation with the earliest-flowered examples longer than when the principal head of bloom gets shabby, as upon getting the shoots ripened and their being cut down at the proper season depends their ability to flower early next year; do not in the first instance withhold water so as to cause the foliage to flag and die off through the deprivation of moisture, but as soon as the leaves droop give a little, gradually withholding it until growth is so checked that the foliage will retain an erect position even when the soil is quite dry.

Fancy Pelargoniums.—These plants, with their beautiful delicate colours, are now so little in favour, that they are comparatively seldom met with; still, to those who like to grow some subjects of a naturally formal habit by way of contrast to others of more free and elegant outline, with a disposition to produce a complete sheet of flowers of the softest tints, it would be difficult to point to any plant that will supply the place of these Pelargoniums. In their case it is not necessary to allow the soil to get so dry through the absence of water as in that of the stronger-growing selfs, and if exposed out-of-doors, care must be taken that they do not get too wet during heavy rains, as they are very impatient of over much moisture at the roots, the effect of which is generally the destruction of the fibres, and that kills the plants.

Mignonette.—Where large examples of this are grown for winter flowering they necessarily require a much longer time to grow than the small pots of late summer and autumn-sown Mignonette generally in use; but where there is an attempt to grow this plant to a considerable size, although comparatively easily managed, unless its wants are constantly attended to, the specimens will be more remarkable for size than condition, as evidenced by the spare, yellow-looking leaves and small spikes of bloom that weak, attenuated plants often display. Mignonette does not like much disturbance as

regards the roots, and it is well to get the early-grown stock in sufficiently large pots before the season is too far advanced, so as to avoid any cramping at the roots, for should this occur, it is a difficult matter to get them to move freely afterwards; use the soil fairly enriched and pot firmly, giving the plants a good light position, placing them far enough apart in the house or pit in which they are grown; stop and tie out the shoots as growth progresses. The ordinary bushy or pyramidal form will in most cases be found to look the best. The ugly wire trellises sometimes used for Mignonette, where at the time of blooming it frequently happens that the wire is as conspicuous as the shoots of the plants, cannot be too much condemned. Look well to the undersides of the leaves for green fly and red spider, which, if present, very quickly ruin the plants. Water, to which has been added a handful of soot to the gallon, stirred up daily for a week, and the plants from time to time syringed with it, has an excellent effect in removing these insects, and also in rendering the foliage unpalatable to them. A little soot water applied to the soil both assists growth and helps to keep the leaves of that dark green colour which adds so much to their appearance as well as to the requisite strength. A little more seed may with advantage now be put in to grow some plants on in small or medium-sized pots with a view to their blooming before those latest sown.

Cinerarias.—The earliest sown plants should not be kept longer out of their blooming pots than when they have got the soil in those they already occupy fairly filled with roots, for with these again any check will result in the destruction of their lower leaves, the loss of which not only destroys their appearance, but so far weakens them that it is never possible to get plants which have thus suffered to produce anything like the head of flowers they otherwise would do. Keep the early and later-sown stocks where they can be slightly shaded from the sun during the hottest part of the day, particularly in the case of plants that are treated so as to make free vigorous growth, for where the foliage thus gets to a large size it is, as a matter of course, softer than when of a small stunted character; some well decomposed leaf-mould added to the soil, as well as thoroughly rotten manure, assists free growth. Where grown from suckers, and the plants from which these are taken were, after blooming, as they ought to be, planted out, the suckers much sooner attain a good size, and they will in every way be easier managed than when kept in pots. As soon as any of the suckers are large enough take them off, allowing the small ones succeeding to remain longer. When so grown it is not well to remove them from the old plants until they have attained a good size and plenty of roots, plants from such invariably keeping the lead of those taken off whilst small and weak.

Primulas.—Plants raised from the earliest sowing will soon be ready for moving into their flowering pots—5 in. or 6 in. in diameter will be large enough; ram the soil tolerably hard, by which means I have found them less disposed to produce leaves with long weak stalks that have a tendency to damp off; in potting keep the plants well down, so as to avoid any bare stem betwixt the soil and lower leaves; frames or pits facing the north, with the plants raised close up to the glass, and thinly shaded during the middle of the day, will be found the right position to place them in, the result being growth which will not only afford a full complement of flowers, but which will be much less disposed to damp in the winter.

Chrysanthemums.—Nothing tends more to preserve the foliage, to assist growth, and to minimise the drying influence of hot weather than keeping the pots plunged up to their rims; if coal ashes be available they are much the best, as they keep out worms, which, though not injuring them to the extent of more delicate-growing subjects, are still much better absent from the soil. The plants should now be treated in accordance with whatever form they are to be grown in. The ordinary bushy form of tying, by the use of a few sticks keeping the branches sufficiently far apart to allow plenty of air to get to the whole, is the most generally useful; but some dwarf standards that are grown to a single stem from 2 ft. to 2½ ft. or 3 ft. in height and stopped, so as to cause them to branch freely, are particularly useful when the plants are to be used in rooms, halls, or corridors, and also for relieving the too even surface which a stage full of these plants when in bloom often presents. If the plants are at all affected with green fly, the shoots should be repeatedly dipped in Tobacco water, which they will bear using stronger than most plants, until the insects are completely destroyed, to keep them clear from which the whole stock should be syringed feely with clean water every evening when the weather is dry. It is well not to grow a greater number than is required, or there is time at command to give sufficient attention to, for, as with most other things, a better result may be attained with a limited number of plants well grown than larger quantities worse managed.

Flower Garden.

Grass has grown vigorously during the past month, and is still continuing to do so, necessitating frequent mowing and rolling to keep it in good condition; now is the time to form a good sward, and the closer and oftener it is cut and rolled the better will the bottom be, and the more effectually will it withstand the ensuing winter, should it be severe; few things add more to the beauty of gardens than good and well-kept Grass, and the work is so simple that it should be by no means neglected.

During wet weather it is almost impossible to maintain borders free from weeds; in those instances where they are much over-run the best plan will be to lightly dig them over, taking care not to injure the roots of the trees, shrubs, or herbaceous plants; where this cannot be done the weeds must be hoed up and raked off or hand-picked. Overgrown shrubs may be pruned back to within proper limits, and all herbaceous plants requiring it should have supports. Annuals must be thinned out, and all subjects in the way of Asters, Stocks, Helichrysums, &c., still in store should be planted out in favourable weather without delay. Seeds of perennials may also be freely sown for stock next year or for spring bedding.

Fruit.

Incessant warfare must still be waged in the case of aphides. Soap-suds or clear water applied with force are the best antidotes, but they require frequent repetition, and before washing and dressing the trees, all the curled and blistered leaves and the worst effected and superfluous shoots should be removed, and the final tying in of shoots should be delayed until the trees are quite clean and healthy. Pears are now sufficiently advanced to have all the breast-wood cut away at about, say, four joints from the main stem; if cut closer they are apt to again break into strong wood growth rather than form fruit-buds. Currant and Gooseberry bushes have made much growth, and thinning it out will therefore be a matter of necessity. Summer pruning of these has many advantages, not the least being that the trees can be trimmed into any shape desired, and the fruit at the same time be exposed to the influences of the atmosphere. Currants and Cherries are changing colour, and will require protection from birds; any that are to be reserved for a considerable time should be cleared of aphides and be closely covered up with hexagon netting. Ripe Strawberries often suffer more from mice and slugs than from birds, and it will be desirable to at once adopt precautionary measures against these; trap the former with the common figure of 4 trap, and the latter by means of baits of bran. If Raspberry stools have not yet been thinned they should at once be reduced to four shoots each, or if thickly together three will be ample. Mulch the ground about them with good rotten manure, for drought would soon have a deteriorating effect.

Vegetables.

No sooner is one crop planted or sown than another requires thinning, another earthing and weeding, and another lifting or harvesting, in order that the ground may again be prepared for cropping. Such is now the case with Shallots and Garlic, which, in many instances, will be ready to be taken up; they should not be allowed to remain after the tops have dried off, but pulled up and left on the ground a day or two to dry, and afterwards tied up in convenient bundles for use, and hung up in a shed or other airy, cool, dry room. The ground where they have been grown, if well dressed when they were planted, will not now require digging, but simply levelling and weeding, drawing drills afterwards for the sowing of Endive or black-seeded Bath Cos Lettuce for early winter use. If it be thought desirable to preserve the stock of any good variety of vegetables, such as Cauliflowers, Lettuce, &c., select the most perfect types for seeding, and stake or otherwise mark them in order that they do not get cut when the crop is being used. No two kinds of Cabbages, Brussels Sprouts, or Cauliflowers should ever be seeded together if the stock be desired pure, for bees are wonderful hybridists, and are not particular as to how or on what they operate.

Tomatoes are now growing freely, and will require to have their growths trained or tied in; if there be a tendency to strong growth, repress it by severe pinching of the lateral growth, an operation which also promotes fruitfulness. If the fruit set too thickly, thin it out and remove all the large leaves that keep the light off it. As a rule, high feeding is not necessary for Tomatoes, but if bearing freely they may be assisted by an occasional watering with weak liquid manure.

Spinach.—Where this is required all through the season seed must be sown regularly every fortnight, as it will not stand much beyond that period without running to seed; any vacant spot that can be cleared from other plants may be used for this purpose. As the crop of Cabbage is cut strip the leaves from the stumps, as they only harbour slugs and caterpillars; give the ground a good soaking with manure water to assist the stools to throw out fresh side shoots, which will furnish through the remainder of the season a useful supply of tender sprouts.

Leeks which were sown at the proper time and thinned out in the seed-bed, so as to give them enough room to grow will now be in good order for planting. The ground they are to occupy should be well dug to the depth of 15 in. and broken fine, so as not to leave any large hard lumps. Plant in rows 15 in. apart, with 8 in. or 9 in. between the plants, and in planting use a stout dibber that will make holes 8 in. deep and 2 in. or a little more in diameter. In these place the plants, dropping in soil to the depth of 1 in. or 2 in., but no more, leaving the rest of the hole open and giving a good watering, so as to settle the soil. By only partially filling the hole the requisite air gets down to the roots, and the opening above affords space for the stems of the plants to thicken, and also blanches them in a way that imparts the peculiar delicate flavour which a well-grown Leek possesses. If the ground be good and well enriched, they will, under this treatment, grow almost as thick as a man's wrist, and are far superior to the small tough, strong-flavoured specimens of this vegetable which are often to be met with.

GLASSHOUSES AND FRAMES.

WATERING PLANTS IN POTS.

WATERING constitutes a very important part of plant culture. As a rule, all greenhouse plants of free growth want a constant and steady supply of moisture at the roots during the growing season. The soil should neither be soured nor rendered sodden through repeated waterings that are not required, nor through defective drainage—a fertile source of mischief in this respect—nor should it ever be even moderately dry. This, however, is just the difficulty. A plant should never be allowed to suffer in the least from want of water, for it means starvation and worse; and yet it should not be overwatered. The beneficial effects of plunging plants in pots in soil, ashes, Cocoa-nut fibre, &c., are wholly the result of an equable degree of moisture and temperature at the roots; in watering, therefore, these conditions must be imitated as far as possible. The first essential is to drain the pot well, and the next is to leave room on the surface for it to hold water sufficient to soak the ball thoroughly. The practice of filling the pots too full of soil in potting cannot be too severely condemned, and yet it is all but universal. The consequence is, that when the plants have to be watered, nothing like the necessary quantity can be given them at once, and there is all the trouble of going over them again, perhaps two or three times, until each is thoroughly soaked. But what follows if the

plants have only been served with a driblet each? By midday they are probably flagging, and if they happen to be noticed, a quantity of water is fetched from the nearest tank and dashed in among them immediately, as a temporary supply; and thus the practice goes on, entailing the most disastrous results. The time to water is early in the morning, or in the evening when the heat of the day is over, and always when the ventilation is reduced to its minimum. Water should never be given when evaporation is going on rapidly, particularly in greenhouses and conservatories, where the plants are usually placed on dry, airy shelves and stages, and exposed to draught on all sides. Some plants are more impatient of neglect in watering than others. Among these is the Heath, which, always being potted in peat well rammed into the pot, requires considerable attention in this respect. Heaths should always be watered before they get dry. Plants that have been shifted on from one sized pot to another are very apt to get dry in the centre of the ball; and when this occurs no amount of watering will soak it—the water simply runs past it, and in the end the plant gets sickly and dies. Pushing a small stake down the centre of the ball usually reveals the state of affairs; and if the ball is found to be dry, steeping it in a tub of water for a day or more, or until the bubbles of air ceased to rise to the surface, is the best remedy. The stake test is not to be recommended, however, unless drought is suspected, for it injures the roots in its passage through the soil. The Camellia is another subject often ruined through careless watering. Planted out, it grows like a Laurel bush; but in pots or tubs, unhealthy, scraggy specimens, that drop their buds just before they should expand, are too common. The Camellia is an uncommonly close and abundant rooter; the roots permeate the soil thickly in every direction, the ball near the stem being generally a complete mass of fibres, which drink up an inconceivable quantity of water; and if this be not supplied regularly, the soil gets dust-dry, and then, as with the Heath, steeping is the only alternative. Years ago, I had occasion to re-tub a large number of Camellias. They had been top-dressed frequently, but had not been shifted for a number of years, and many of the larger plants were in an unsatisfactory condition, not having made such growth annually as might have been expected. The shifting explained matters, however, for nearly all were dry in the centre of the balls. It was suspected that the plants had suffered a year or two before from too little watering, and copious supplies had been given them at intervals since that time, but, as it now appeared, without effect. After removing the outer soil and top-dressings, which did not contain many roots, the balls were found to be dry, matted, and so hard, that it required a good dig with a stout Oak peg to make any impression on them. They were all steeped for four-and-twenty hours in the water-tanks, and afterwards repotted, many of them going into less tubs or pots than those from which they were shifted. Plenty of room was left for water, and a kind of basin was formed round the necks of the plants to insure its passage through the ball, instead of down between the sides of the pot and the soil—a channel through which the water too frequently finds its way in pot-bound plants. Even in the case of Camellias planted out in a bed, after having been grown in pots for a time, it is advisable to guard against the balls becoming dry. I have seen plants lifted which were just as bad in this respect as if they had been in a pot. When they are planted out young and the roots are allowed to extend freely there is little or no danger. Among other susceptible subjects in the matter of watering are Cinerarias and Calceolarias; neither can bear drought at the root without injury. They will either go back, and perhaps go off altogether, or they will be attacked by aphides; and there are no plants so difficult to fumigate effectively as those just named—in fact, I never care to subject them to Tobacco smoke if it can be avoided. Both enjoy light and sunshine, but a cool bottom of flag or sand they must have; also good drainage and copious waterings. Under these conditions they are rarely troubled with insects, and the plants grow freely. Among stove plants Ferns are perhaps the most sensitive. They like and must have plenty of water at the roots, and they enjoy a position above a water-tank, where the evaporation is constant, but they do not like immersing in the water, even to the extent of 1 in. in the pot. In an aquatic house this was tried with Ferns and Caladiums, but neither throve so well as judiciously-watered plants grown in the shade. C.

A Wall Fernery.

LANTANAS AND THEIR CULTURE.

OWING to the fact that the Lantana is not so brilliantly effective as the generality of flowering plants now so extensively employed for summer bedding and general decorative purposes, it has never become very popular in English gardens. Now and then one sees this plant well cared for; but in the generality of large establishments it does not appear to be held in high estimation. And yet the Lantana possesses certain valuable properties which recommend it to the attention of every gardener. Not only is it of extremely easy culture and propagation, but it is also of a very vigorous, enduring nature; and in the case of many of the varieties the flowers exhibit shades of colour of a rather uncommon description. Those who have soils of a light, porous, parching description to deal with would find in the Lantana a valuable and trustworthy auxiliary, as, owing to its wiry and enduring nature, it thrives where many flowering subjects can scarcely be kept alive. This plant may be regarded as a very good substitute for the Verbena, and may be used with good results where this favourite bedding subject is a complete failure. In Continental gardens the Lantana, owing to its capability of resisting long periods of drought with impunity, is a great favourite for open-air decoration, and is also largely grown as a pot plant for market. The Lantana is indeed, owing to its neat compact habit, an excellent plant for pot culture, flowering profusely in small pots, and being equally well adapted for the formation of large specimens, in which state it is very useful for the embellishment of large conservatories, corridors, and such like places. With a little management, too, it may be had in full bloom from early spring up to quite late in the autumn. For early flowering, the great point is to secure neat little well-furnished specimens established in 2½-in. and 4½-in. pots by the autumn months. The present is an excellent time to put in a batch of cuttings, which, if well attended to, will speedily make roots, and if potted off directly and grown along without check, will be all that can be desired by the end of the growing season. In any case, even where the Lantana is used only for the open air, a few cuttings of each kind should be struck, unless a plant or so of every variety can be kept in pots, for this plant is apt, especially in dry summers, to run so much to flower as to render it a matter of some difficulty to procure fine cuttings; and unless the wood is very succulent they fail to make root with sufficient freedom. A cutting of which the wood has become in the least hard and dry should never be inserted; for even if it emits roots, it never develops into a free vigorous specimen.

The Lantana will strike readily at the present time under a hand-light in a close house. When rooted, pot off in some light well-sanded soil, keep them rather close for a few days, and then place them in a cold frame. Ventilate freely, drawing the sashes completely off on still moist nights. Shade slightly for an hour or so in the middle of the day in very hot weather, using the syringe freely both morning and evening. When the young plants have become established in small pots, stop them back two joints, and shift them into the next-sized pots as soon as they push into growth again. By keeping them well pinched back throughout the summer they will form compact little bushes by the early autumn months, when, having well filled the soil with fibres, they should be placed in the most airy and sunniest situation in the garden, there to remain until the advent of inclement weather, when they will have to be placed in a cool greenhouse. The Lantana, unlike the generality of soft-wooded flowering plants, does not need any great care during the winter season. Until the return of the bright days, and when starting anew into growth, the plants may be stored away in a corner of the structure; or they may be kept safer underneath the staging, provided they receive a certain portion of light and do not get at all soddened by drip. The best way is to lay the pots on their sides; when resting on the damp earth the soil will remain for a considerable time in a sufficiently moist condition, thus obviating the necessity for frequent waterings—an advantage in the present instance, for the Lantana dislikes much moisture at the root during its resting season, a slight overdose of water being sufficient to kill the fibres.

If it is desired to bring any portion of these plants into bloom at an early period of the year, they should be placed in a light warm house by the beginning of January. When fairly started into growth they may be either shifted into larger pots or liberally fed with weak manure water. For very early flowering the latter course is preferable, as a plant always forces best when the pot is crammed with fibres. A few plants should be retained for propagating purposes. Free healthy cuttings taken off during the early spring months strike readily and grow with great freedom, making, if grown along in a genial atmosphere and carefully hardened off, the best of plants for bedding out; or, instead of turning them out in the open air, they may be shifted along and kept growing freely in a cold frame, when they will prove very serviceable for summer and autumn conservatory and window decoration. The Lantana has a very pleasing appearance when grown in standard form. When elevated upon a stem some 2 ft. or 3 ft. in height, allowing the head of foliage to develop somewhat unrestrainedly, the decorative capacities of this plant are displayed to the best advantage. Plants thus grown are excellent subjects for the formation of groups, and are likewise admirably well adapted for dotting amongst dwarf-growing flowering plants in the open air.

JOHN CORNHILL.

Ferns on Old Walls.—The accompanying engraving offers a suggestion of beautifying old walls that might be carried out in many gardens where old stone or brick walls exist. If small plants were obtained in spring and planted between the stones or bricks with a little soil, they would soon become established, and form a perfect wall Fernery; or seeds might be sown with every prospect of success. Walls shaded from the hot sun of summer are best suited to this purpose; and at the foot of such walls a rockery might be made, which might be planted also with Ferns or alpine rock plants.

The Cape Ivy (Senecio macrogiossus).—Most people are acquainted with the German or Parlour Ivy, that quick-growing tender plant now so popular for window and basket culture,

and so useful for soon covering a screen in the garden. The German Ivy is not an Ivy proper at all, but belongs to the great Composite family; it is Senecio scandens, and own brother to the Groundsel, a common weed, to the Tassel flower of the gardens (sometimes called Cacalia), and to that golden-yellow Squaw-weed, or Golden Rag-wort (Senecio aureus), which is everywhere so bright, especially in wet places, in spring. This new plant has received in Europe the name of Cape Ivy, and it well distinguishes it from the other climber, which, though called German, comes from the same locality—South Africa. After growing the plant for a few weeks we had an engraving made of it, which, while the leaves are not so large as they would be on a stronger plant, gives a good idea of their shape and Ivy-like appearance. While the colour of the better known German Ivy is of a light and rather yellowish-green, the leaves of this have the dark and blackish-green so peculiar to true Ivy, and which gives to this newer one a richness which the other lacks; besides this, the leaves have much more substance than those of the other, though they are still soft, and have not the rigidity of those of true Ivy. This Cape Ivy is quite as well suited to house culture as the other. If it proves to be as manageable as the German Ivy, it must become very popular, on account of its finer colour and closer resemblance to Ivy.—*American Agriculturist.* [It may, no doubt, be now obtained at any of the principal London nurseries.]

ANSWERS TO QUERIES.

2303.—**Blight on Fruit Trees.**—Anything that cleanses the young growth from filth or insects is beneficial to a fruit tree, and soapsuds if employed in time are exceedingly useful; but it does not follow that a solution of soda will be equally so, as if given too strong it will be hurtful. Try it on a branch or two first, and regulate the strength by the effect observed. Soda has a saline basis, and should be used carefully and after experimental trials.—E. H.

2299.—**Vines not Fruiting.**—Keep the growth of the Vines thin to secure well ripened wood. This matter is often neglected by amateurs, but it is a most essential point in Grape culture. Probably also the roots are too deep; if they could be carefully lifted early in September and brought nearer the surface fruitfulness will be obtained. When the lifting is done the house should be shaded till the roots are active again.

2283.—**Asphalte for Walks.**—There are various ways of asphalting a walk. The following is a good, simple, and cheap one:—Have the foundation levelled; put on it a coat of coal tar, and sift some road sand or coal ashes over it thickly. When dry put on another coat of tar and sifted ashes or sand, and so on until a sufficient substance has been given, or, say, until four coats have accumulated. The work should be done when the weather and the materials are dry, and the roller should be used over the sand to level and firm the surface.—E. H.

2308.—**Shelter for a Garden.**—This evil is often felt in walled gardens, and is generally remedied either by planting hedges or erecting screens of Reeds at right angles across the border. Wherever it can be done, it is best to plant a belt of fast-growing trees on the windward side outside the garden to break the force of the wind, and lift it over the garden. For a temporary purpose a screen made of Reeds will suffice.

2325.—**Roses Losing their Buds.**—The Rose trees are out of health; probably the roots are in a bad condition. Perhaps the soil is in a stagnant state; the presence of the worms seems to suggest as much. Thin out some of the old wood, and encourage new shoots to break from the bottom or any other part of the trees, which should be laid in full length. In the autumn examine the state of the roots, and remedy any defects observed.—E.

2324.—**Summer Pruning Pyramid Fruit Trees.**—In pruning pyramid fruit trees the leaders should be left unshortened till the annual growth is about finished, unless the trees are young, and it is desired to produce lateral shoots to fill up anywhere. About the middle of June is in the majority of seasons the time to begin, commencing first with those trees that are making the strongest wood, and shortening back all shoots that are not required for filling up the framework of the tree to four leaves. The spurs thus left will require shortening when the leaves fall, cutting to a bud if possible.—E.

2336.—**Grubs in New Land.**—The grubs can be reduced in number by burying pieces of raw vegetables, such as Turnips, Beet, &c., and examine them frequently; they do not eat their way into the baits as the wireworm does, but will be found coiled up near. Cabbage or Lettuce stalks will answer the purpose as well. Soot placed round the stems of Cauliflowers or any other plants it may be important to save, watering it in, will generally keep the grubs at a distance. Whenever a plant flags in the sunshine, scrape the earth away from the stem, and the grub will generally be found eating the bark round the stem just beneath the surface of the soil.—E.

2327.—**Asparagus near the Sea.**—Some shelter would doubtless be desirable, but

The Cape Ivy (Senecio macroglossus).

after the first year or two, when the Asparagus plants were well established the wind would be less hurtful. In windy places, the first year at any rate, the main stems will require support. When the shoots become more numerous they support and shelter each other. The best plan will be to sow seeds on hills 3 ft. apart, half-a-dozen on a hill, thinning to two or three when the strongest can be distinguished. In this way the plantation will acommodate itself to the wind and doubtless be profitable.—H.

2339.—**Rabbit-proof Plants.**—There are but few things really rabbit-proof where these mischievous animals are numerous, but I have never known them to touch Rhododendrons. The following may be planted with a reasonable chance of escaping:—Common Yew, Box, St. John's-wort, Ivy (various), Yuccas, Pampas Grass, Ghent Azaleas, Kalmias, Bird Cherry (Cerasus Padus) Lilacs, Privets, Syringas, Evergreen Oaks, Potentillas, Pyrethrums, Acanthus Achillea (various), Monkshood, and, of course' most of the things that die close down in winte such as bulbs, as it is only during severe weather, when all other food is buried beneath the snow, that they are so destructive. Rabbits very seeds often nibble at newly-planted things when old-established plants of the same speices escape; and in making new plantations it is a good plan to put wire round at first till the plants become established.—E. H.

2369.—**Children's Flower Show.**—If plants, that are strong and of good quality, of such things as Balsams, pyramidal Stocks, Asters (dwarf Chrysanthemums), Fuchsias, Scarlet and other Pelargoniums, shrubby Calceolarias, Petunias, various kinds of Sedums and Echeverias (such as secunda glauca), small pieces of Musk and the Creeping Jenny, Isolepis gracilis, Golden Pyrethrum, Perilla, Phlox Drummondi, and similar easily-grown things be now obtained and distributed amongst the children, with suitable clean pots, and especially good pot soil, then something may be produced by them worthy of exhibition at a flower show next September. If "W. G." could pay a visit to Covent Garden or other plant market, he would find plants of all these and numerous other things there being sold at a cheap rate; or they may be obtained through nurserymen who advertise in our columns from time to time. Seed sown now or cuttings put in would give but meagre results indeed for this season. The cultivation of the plants grown by children, and, indeed, by all who have only windows for greenhouses, is so difficult, that it is not possible to obtain results other than such as complained of. It is not possible that under such conditions they can do more than give all the air and light that is available, and it will be found that the best specimens are those grown where these conditions are most favourable. A collection of vegetables for September should consist of Potatoes, Turnips, Carrots, Vegetable Marrows, Runner and Dwarf French Beans, Cabbages, Cos Lettuce, or say any six of these varieties. Potatoes should have been planted in April; Turnips may be sown at once, Carrots last month; Marrows must be planted out; Runner Beans should be up and Dwarf Beans sown now; Cabbage plants ready to put out and Cos Lettuce sown at once. Flower shows of the simplest kind need long preparation, and should always have full six months' start to give hope of success.—A. D.

2358.—**Camellias Out-of-doors.**—There is really no reason why Camellias should not succeed near Bedford, or indeed anywhere throughout the midland districts. The soil most favoured is a black or as often called peaty loam, but stiff clayey loams are not favourable. Camellias are absolutely hardy, even more hardy than the Laurel, and when once established rarely if ever are injured by frost. The annual growth is never luxuriant, and is always made early, and therefore is well ripened by the summer sun. It has been the rule in many places to protect them in winter even on walls, but that has been only where the old and now exploded notion prevailed that the plants are tender. Outdoor cultivation really does not materially differ from that of any other hardy shrub; they simply want when once established to be let alone, except that in hot dry

weather a little mulching with decayed manure would be useful. The plants prefer moderate shade to full exposure to the sun. Camellias being turned out of pots may be planted at almost any time, but such plants should have been partially prepared for planting out by a gradual process of hardening, as most plants are raised and grown on under glass, and that is not a good preparation for sudden and permanent exposure in the open air. If the plants were plunged whilst in pots in a shady place, and in ashes for a year first, they would go out with much less risk. March or October are both good months for planting, the ball being loosened and the roots somewhat distributed. Camellias are almost all equally hardy, but these kinds do well in the open air—Alba plena, Imbricata, Lavinia Maggi, Lady Hume's Blush, Striata, Saccoi Nova, Mathiotiana, Cactifolia, Beali, Storyi, &c. There is no reason why newer sorts should not do equally as well.—A. D.

2381.—**Clay's Fertiliser.**—In reply to "V. A. V.," I cannot say what effect Clay's Fertiliser would have as a manure for farming, but I must in justice to it say that it is the most wonderful in effect of any manure I have ever tried on pot plants, or on such things as Asters, Carnations, Bouvardias, Solanums, or other plants usually planted out. Its properties do not get washed out quickly, but make the soil permanently better after each dressing. It is the only manure I use, as with it I can sell a stimulated plant, knowing that the means of keeping up its health goes in the pot with it. The proportions I use is a 4½-in. potful of Clay's to a barrowload of soil for potting, and one part of Clay's to ten of soil for top-dressing. It should never be given in water.—JAMES O'BRIEN, *Pine-apple Nursery.*

2344.—**Maggots on Holly Leaves.**—If the Hollies are only small specimens, crushing the maggots between the finger and thumb may perhaps be possible; syringing the trees with something distasteful will be useful if done about the time the flies lay their eggs. A solution of soft soap, 3 oz. to the gallon, or a decoction or infusion of Quassia chips, 3 oz. to the gallon, would be still more effectual. Dustings of soot, if carefully applied, will also be serviceable. Hellebore powder, dusted on when the trees are damp through a muslin bag, will kill the maggots; so would fresh lime applied in the same manner.

2332.—**Club-footed Cabbages.**—The Cabbage grub, which is the origin of the disease called clubbing, is the larva of a species of beetle. Removing the crop to fresh ground, dressing the roots in a puddle of soot, lime, and liquid manure just previous to planting are safe practices to follow. Making wide holes with a crowbar and filling them with compost, of which soot and lime form a part, and planting a young plant in each hole, is a sure way of securing a good clean crop. Probably the old seeds may have produced wiry, harder stemmed plants than the new, and so escaped their attack.—E. H.

2354.—**Honeydew.**—There can be no doubt whatever that Honeydew so called is but the exudation of the aphis or green fly, ejected by them at certain periods, but not always. Probably the state of the weather or condition of the plant upon which they feed or their own age may have something to do with it. We got recently good observation on this matter in connection with a large Rose tree under glass, which, during the prevalence of dry parching east winds, suddenly became greatly infested with aphis. In a few days the upper sides of the leaves near to the insects were covered with the exudation, and on those on which the matter was thinnest it was easy to observe that it had been cast on the surface from a certain direction and then slightly run, just as a drop of moisture of any kind might do. All trees affected by aphis will exhibit this feature. The Black Currant leaves just now are much so, the insects gathering upon the underside of one leaf and ejecting their exudations upon the surface of the leaf or leaves next below. Ants notoriously love to infest plants where aphis are gathered, not, as some have thought, to feed upon the insects, but simply to cull from them the sweets or Honeydew thus stored by the aphis.—A. D.

—— This fluid is considered to be produced by a species of aphis furnished with two minute tubular vessels at the end of the body called cornicles. From these they eject a sweet drop which we call honeydew. This species of aphis is more especially partial to Roses, Geraniums, and Cinerarias. Ants are very fond of this substance, and will infest the same plants for the sake of it, though not attacking the aphis itself. —S. S.

2356.—**Spotted Mimuli.**—A plant of Mimulus that has made shoots 20 in. in length is no doubt somewhat out of form and condition. The best plan in such case is to cut the shoots close back to the pot and encourage new growth from the root. Cuttings taken from such new growth would strike freely, but it is very doubtful whether any made from the old shoots would do so. The flagging is most probably due to the soot water, which may have been too strong. Soot is a very stimulating manure, and requires to be used with discretion. A dose that a healthy plant may take up with impunity may kill another one of weak habit. If you have seed, sow at once and raise young plants—that is the best way to get stock.—D.

2305.—**Perennial Pinks.**—We must infer that by the term perennial Pinks you want single-flowered kinds of the common garden Pink. Of this section of the Carnation—for Pinks are but forms of the Carnation—single kinds are not common, and Pink seed is scarce; but seed of the single Clove Carnation is plentiful enough, and should be obtainable from any seedsman. Single Carnations of various hues of colour are very largely grown around London for market sale, but the larger portion go into the hands of the hawkers, who purchase them at about 6d. per dozen in April and May, and then, in some cases, hawk them about the country with the roots massed and labels attached, to induce the unwary purchaser to believe that they are double kinds. All these may be bought cheaply in the market, and all seed freely; they make admirable cut flowers, although much less beautiful than are blooms of the double kinds. In the trade these single kinds are called "Jacks," and the best strain is that which has the broadest leaves, because such plants are thought most to resemble the double sorts. Continental seed, such as is sent over here at a moderate price by the French growers, also give a large proportion of single flowers; but some are double, and often very good. A fault with many of these Continental seedlings is to bloom so freely that they make no wood or grass; and thus the plants die in the winter. The Indian Pinks (Dianthus chinensis), &c., are all very beautiful; many are hardy, and they make a magnificent bed, but during severe winters could not be relied upon. The "Jacks" give the hardiest strain of single kinds.—A. D.

2289.—**Propagating Deutzia gracilis.**—Deutzia gracilis, when well grown, will throw up new growth or suckers from the roots, and these may be taken off in the autumn with a sharp knife, a portion of root being attached, cut back to a few inches, and then be potted. The portions cut away make the best of cuttings. These should be about 3 in. in length, and, if put into pots and kept in a frame or cool house, will, as a rule, strike well in the spring. If placed in a gentle bottom heat, rooting will be much accelerated. The young plants will do well in a cool frame in all seasons, but make more rapid growth in heat, and the earlier the new wood is produced the earlier is it matured. —D.

2290.—**Antirrhinums in Pots.**—The finest spikes of blooms from Antirrhinums are, as a rule, obtained from plants that are turned out early in the spring or have stood the winter. These will throw up strong flowering shoots from the root, and produce grand spikes of bloom. If wanted to bloom in pots, good plants ought to be had, if the healthy seedlings be shifted into 7 in. pots and have some good soil, but it is certain that the finest spikes, nevertheless, will only come from the root shoots. We have just now in bloom a robust plant of a fine striped kind that has produced some nine or ten fine spikes, from 6 in. to 9 in. in length, and yet the plant is growing only on solid brickwork. This fact seems to show that the Antirrhinum is a semi-rock plant. Our rule is to sow seed in the spring to produce plants to bloom in the autumn, and these, standing the winter if not too severe, produce grand spikes of bloom the following June.—D.

2382.—**Plants for Exhibition.**—For the purpose of having Pentstemons, Antirrhinums, and annuals in pots in bloom at the end of August it is not necessary to have any kind of artificial warmth, and if under glass at all the best place is a cold frame, but most of these things are best in the open air. Still, the present treatment must depend upon the state of the plants, as if advanced then it may be necessary to keep them in a cool place to retard them; whilst if not too forward then, the plants may want to be pushed on in a warmer situation. Pentstemons and Antirrhinums ought to be fairly strong plants, well established in 6-in. pots. Pansies should be well rooted cuttings, newly potted in good soil and kept growing on in a cool place. The first flowers from Pansies are always the finest. Stocks and Asters should be strong and well established in pots, the former about two or three plants in 6-in. pots; the latter are best if lifted from the open ground into pots when in bloom, as they are then so much stronger. Geraniums, as you call them, but really Pelargoniums, should be well rooted plants also in 6-in. pots, and should be kept pinched and have all the bloom-buds gathered off until five weeks before the time for showing them. From that time they may be allowed to come away and produce all the flowers possible, and the same rule will apply to Fuchsias. The application of liquid manure must be regulated by the state of the plants. If well established and the pots are full of roots, then weak liquid manure may be given twice a week, but it is better to err on the side of weakness than strength, as in the latter case a few overdoses may destroy the roots. As in the exhibition of any kind of plants habit goes a long way, care must be taken not to have the plants drawn or lanky, but as bushy and compact as possible. —A. D.

2398.—**Annuals for Exhibition.**—It is altogether too late to sow annuals to flower next August. This should have been done in April or early in May. If plants of the kinds required can be purchased so much the better, but if not, then we cannot help you in that direction beyond pointing out the best sorts for the purpose named. Six good hardy annuals are Mignonette, new carmine Candytuft, large Indian Pink (Dianthus Heddewigi), Godetia Lady Albemarle, Chrysanthemum Dunnetti (double yellow), and Clarkia elegans (double red). Of half-hardy annuals, pyramidal Stocks, Victoria Asters, African Marigolds, Phlox Drummondi, spikes of Balsams, and double dwarf Larkspurs.—A. D.

2403.—**Plants for Empty Room.**—At this time of the year almost any ordinary plants that thrive in pots may be grown in an empty room if the light be good and plenty of air given. For foliage, India-rubber plants, green and variegated Aralias, a cool Palm or two, such as Chamærops Fortunei, a few greenhouse Ferns, such as Adiantum cuneatum and Pteris serrulata, will do; and for flower nothing will be better than zonal and nosegay Pelargoniums of various colours, Fuchsias, Petunias, shrubby Calceolarias, Balsams, and, indeed, any kind of greenhouse plants that may be in season. How they would thrive must be determined by the attention given, light, air, and other essential conditions to plant life.—A.

2383.—**Spiræa japonica Failing.**—Having no knowledge of the conditions under which the Spiræa japonica was grown, it would be difficult to give an exact reason. It might have been exposed to strong gaslight, or it might have been permitted to get too dry at the root, or it might have been swamped by moisture, although this latter case is not so likely, as the Spiræa takes up a large quantity of water when it is fairly pot-bound. There can be but two reasons—either injured at the root by some poisonous water, or by exposure to an atmosphere that was full of poisonous gasses.—D.

2391.—**Hollyhocks not Growing.**—That Hollyhocks do not now show flowering stems is no proof that they will not bloom this year, as they may yet do so and flower quite late in the autumn. Their lateness must doubtless be attributed to their being so recently planted. This should have been done in February or March to have enabled the plants to get well established. That the leaves thrown up are on long stalks would seem to indicate that the sur-

roundings serve to draw the foliage; still, there can be no doubt but that flower-stalks will come presently.—D.

2292.—**Anemones not Blooming.**—It is most likely that the soil in which Anemones are growing but do not bloom does not suit them; or it may have been that the excessive rainfall of last summer did a lot of mischief to the roots, decaying rather than ripening them. It will no doubt be wisest to lift the roots and examine them, and, if sound, store away in dry sand in a cool place until the end of September, and then replant in good free soil.—D.

2412.—**Double and Single Stocks.**—It is not possible to distinguish double from single Stocks before they are in bud, but the moment buds appear it is possible so to do by picking off a bud from each plant and testing it between the teeth; if gritty, then it is single, because it contains fertile organs; if not gritty, then it will be double. It is our experience in relation to that beautiful summer pyramidal Stock Mauve Beauty that all the strongest plants are double, the weaker ones being single, but this may not be a safe rule to go by in all cases.—D.

2366.—**Worms in Gardens.**—Strew fresh soot and warm slaked lime over your garden in the evening, and the worms will disappear as if by magic. They detest these dressings. Lime water made by allowing a few lumps of lime to impregnate a tubful of water, and then using the liquid when it is clear through a watering-pot, will kill many. It is not probable that worms have much to do with thinness of Beans and Peas; the seed is no doubt at fault, as what you complain of is universal. Get a few ducklings to run in the garden; they are notable devourers of worms.—A.

2370.—**Sparrows Eating Pyrethrum.**—When birds eat Golden Feather, they show a singularly depraved taste and a curious fancy. There is really no method of preventing this but by protecting the plants from the sparrows, or by shooting the marauders.—D.

2371.—**Prickly Comfrey.**—We do not find that fowls are partial to the Comfrey, and cannot think that even pigs would care for it, although cows like it. Boil some and give it to the poultry and pigs, and see if they like it, but in a raw state it is most improbable that it will prove acceptable.—D.

2337.—**Plantains on Lawns.**—Plantains on lawns are difficult to eradicate, but perseverance in digging them up will accomplish it in time. Vitriol or salt dropped into the cavity from which the crown of the plant has been taken should be effective. In bad cases it will be better and cheaper to pare up the turf, dig the land over, and sow good Grass seeds next September.—E.

2345.—**Pigeon Manure for Plants.**—This is a difficult question to answer, as the strength that would kill one plant might benefit another. It is of a hot nature, something like guano, which is neither more nor less than birds' dung. It should be used cautiously and experimentally at first. Thus, say, for potting Fuchsias mix ¼ peck of pigeons' dung with 2 bushels of ordinary compost. The birds' dung should be kept dry.—H.

2346.—**Barked Apple Trees.**—The Apple trees will probably die. The only thing that can be done is to cover the wounded parts with something to keep the air out till new bark can be formed, but if the inner bark is gone even this will not avail. A paste made up of old mortar and cow dung and placed over the wound may be useful.—E.

2342.—**Daisies on Lawns.**—It is not an easy matter to keep a lawn free from Daisies, as the seeds are often scattered by the wind; and if only a few plants gain access they soon seed and increase. Watson's Lawn Sand has been highly recommended, and may be obtained from most seedsmen; and the old-fashioned plan of digging them out by the aid of women and children is a good one.—E. H.

2328.—**Food for Roses.**—By giving the beds a good dressing of newly-slaked lime. Superphosphates are good dressings for such soils, and may be applied now, sprinkling it over the surface and hoeing it in.—E.

2338.—**Roses not Blooming.**—They will flower next year, as neither refuse to flower when they grow well. They usually flower freely on the young wood of the previous year, and as this year they are making plenty of wood and are looking healthy, they will doubtless flower finely next spring.—E. H.

2337.—**Cement for Flue.**—I constructed a flue in my greenhouse with the following mixture:—Equal quantities of fresh cow manure, newly-slaked lime, and road drift (say from a limestone road). I have seen neither smoke nor cracks yet, and can recommend it.—DEPOT.

2341—**Chemical Manure.**—It should have been stated for what crops the manure is required. I am not aware that any special apparatus is necessary for mixing the generality of artificial manures. The following is a substitute for guano, and merely requires well mixing in a dry state:—Sulphate of soda (dry), 11 lb.; wood ashes, 28 lb.; common salt, ¾ cwt.; crude sulphate of ammonia, ½ cwt.; bone dust, 7 bush.—F. W. P.

2292.—**Sweet Brier.**—The Sweet Brier is not so hardy as the common Dog Rose, but it generally lives in the thick hedges, sheltered by other plants, through the severest winters. The last two winters have been destructive to many plants, and the Sweet Brier, where isolated or unsheltered, has suffered severely in many places. Lighten the soil with road scrapings, and try again with seedling plants.—E. H.

2302.—**Moving Asparagus.**—As the Asparagus plants were only planted last March, it will do them but little harm, if any, to move them again now. Open trenches 6 in. or 8 in. deep, and wide enough to contain the roots when laid out straight; let the trenches be 3 ft. apart, and the plants 18 in. apart in them; cover the crown of the roots about 1 in.; water them well in, and mulch at once with manure. In the course of two or three years every alternate plant should be taken out, leaving them 3 ft. apart.—E. H.

2291.—**Vines.**—It will under the close pruning system, but in so confined a space one Vine will probably be better than two. If a Black Hamburgh was planted now, Foster's Seedling or the Buckland Sweetwater may be grafted upon it by inarching in the course of a year or two, so that, if desired, black and white Grapes may be had from one Vine as well as if two are planted.—E. H.

2297.—**Vines Suddenly Failing.**—The Vines have been kept in too confined an atmosphere too heavily charged with moisture. The symptoms all point in this direction. Petroleum oil will not mix with water, therefore I do not think the use of the barrels in the way described can have had any bad effect so far as the water is concerned.—E. H.

2304.—**Summer Pruning Fruit Trees.**—The middle or end of June was early enough this season, unless the trees are unusually vigorous, to begin the general pruning; but gross shoots should be pinched whenever they appear to be acting the part of robbers, as all evil habits are best nipped in the bud.—E. H.

Although the following questions are answered by the Editor, we shall be obliged to any of our readers who may think well to answer them again.

2417.—**Sowing Sweet Peas.**—Is anything gained by sowing Sweet Peas in August or September, so that they make little plants before winter?—F. A. S. [Sow in November, and you will get good plants and early bloom. Sow again in March or April for succession.]

2418.—**Collinsia verna.**—Should seed of this be fresh, and must it be sown in the autumn? Where can I get it? Any information about this annual would greatly oblige.—F. A. S. [Good seed can be got at any good seed house. It may be sown either in autumn or spring.]

2419.—**Vegetable Marrows.**—My Vegetable Marrow plants, although very small and not appearing to grow luxuriantly, are breaking into flower. Should these flowers be pinched off?—LANGLEY HURST. [Yes, until the plants get well established.]

2420.—**Raspberry Canes.**—My Raspberry canes, which were put in last autumn, although in vigorous bearing and covered with fruit, have no young shoots rising from the stools. I have mulched them with rotten manure. Does this injure the young shoots in any way?—LANGLEY HURST. [They will probably throw up suckers after the fruit is gathered and the old canes begin to decline. The manure will help them.]

2421.—**Cotoneaster and Thuja.**—*X. Y. Z.*—The Cotoneaster belongs to a family of small trees or trailing shrubs belonging to the Order Rosaceæ, inhabiting the northern parts of Europe and the mountains of India. The Thuja is a genus included in the Cupressineous division of Coniferæ, and consists of evergreen trees, natives of North America.

2422.—**Plants for Vinery.**—I have a cool Vinery; could I grow Vegetable Marrows or Cucumbers in it? The Vines quite shade all parts. Also what could I utilise the place for during the winter? I have just enough heat to keep out the frost. Could I keep Calceolaria cuttings in it, or old roots of Geraniums?—DARBY. [Neither Cucumbers nor Vegetable Marrows would succeed under the Vines. You could grow some of the hardier kinds of Ferns, also Camellias, Cytisus, Coronillas, and similar plants, which flower in spring, and which can be placed outside before the Vines offer them too much shade. Calceolarias, Geraniums, Fuchsias, &c., might be kept in the house during winter.]

2423.—**Rosebuds Falling.**—*F. L. Kingsley.*—The buds sent appear to have been eaten by a maggot. The reason the perfect buds drop off may be due to dryness at the roots.

2424.—**Onions Failing.**—*Malvern.*—It is the Onion maggot that has attacked your crop. There is no real remedy for it now; you might try a dusting of soot and a little salt. Next year you must try and prevent it in the preparation of the seed bed.

2425.—**Cactus not Flowering.**—*S. G. P.*—Keep them in a sunny position and admit plenty of air. Repot them after flowering if they are pot-bound, but too large pots should be avoided.

2426.—**French Beans.**—*Boss.*—All plants raised from seed lift the seed above the ground when they germinate unless buried too deeply. Try Mustard and Cress, and similar seeds.

2427.—**Green Fly and Gooseberry Caterpillars.** *P. D.*—We have lately given abundance of information on this subject in GARDENING. Search a few of the recent numbers.

2428.—**Spiræa japonica.**—The leaves of some of my plants of Spiræa japonica, recently planted out, are getting dry and withered at the edges. What is the reason?—J. E. [The Spiræa is an herbaceous plant which dies down annually; it is, therefore, only natural that the old leaves should begin to get brown, and especially in plants recently planted.]

2429.—**Vines Failing.**—I have a Grape Vine planted out-of-doors against a wall and trained inside an unheated greenhouse. For a month or two past manure water from a cesspool has been copiously administered three or four times a week, but the leaves are making very little growth and the fruit is all going off.—J. E. [Such frequent watering with strong manure water is enough to kill any plant. The soil has become sour and sodden, and the roots refuse to grow in it. One thorough soaking with water once a fortnight would have been ample. Do not water any more until the soil shows signs of getting dry. Then fork up the surface soil carefully to allow it to sweeten, and when you water use clear soft water, and the Vine may recover.]

2430.—**Destroying Slugs.**—*J. B.*—Lay heaps of bran about the garden, and examine them early every morning.

2431.—**Polyanthus and Auriculas.**—*Jules Margottin.*—The best time to divide these is as soon as they have done blooming, but it may still be done. The best situation is one where plenty of light and fresh air can reach the plants, but where the direct rays of the sun cannot fall on them.

2432.—**Rose Blooms Shrivelling.**—*Jules Margottin.*—Roses are in most places very poor this season, therefore we cannot account for your Rose blooms shrivelling. Even the Briers in many places are entirely killed.

2433.—**Moving Fruit Trees and Shrubs.**—*T. F. M.*—Small fruit trees or shrubs might be moved with a fair chance of success in the middle of September provided their roots be not injured and are packed in soil or Cocoa-nut fibre to prevent them getting dried up during removal from one place to the other. After planting, well water and mulch with manure if possible.

2434.—**Double Sweet Williams.**—*G. A. S.*—These are not uncommon, and, in our opinion, are not so pretty as the single ones. The one sent has no particular merit.

2435.—**Holes in Cherry Leaves.**—*E. L. B.*—If you can find no insect on the trees we can assign no cause for the leaves being perforated. Make a close examination.

2436.—**Retarding Fuchsias.**—*Protector.*—We would advise you to pick off some of the forwardest blooms if they are likely to be too far advanced by the show day. This will give the others a chance of opening to succeed them. Keep the plants in a cool, airy place and away from the sun, and take care they do not want for water at the roots. Manure water must not be given if you wish to retard the blooms.

2437.—**Potatoes among other Crops.**—About three months ago I put some manure in the ground and amongst it was a large quantity of Potato peelings, which grew, and the tops spring up in great numbers and are very troublesome. I have used the hoe and rake to them many times, but they appear to spring up as vigorously as ever. [Pull them up by the roots.]

2438.—**Tobacco Water.**—*A. E. C.*—An ounce of common Tobacco will make a gallon of liquor of good strength. Place the Tobacco in a piece of muslin or thin canvas and let it soak in the water, which should be hot to begin with, for a few hours, squeezing the Tobacco occasionally to extract the juice.

2439.—**Geranium Leaves Spotted.**—*H. King.*—This is not a disease, but is often caused at this time of the year by watering the plants when the sun is on them, or keeping them confined too much in the morning. The sun scorches the leaves when wet. The flowers are not well developed. Give the plants a little clear soot water.

2440.—**Tuberous Begonias.**—*H. King.*—These will grow and flower well at this time of year in pots of light rich soil under glass, or in the open ground. We have seen some very good ones grown in a sunny window.

2441.—**Soil for Wardian Case.**—*Glasgow.*—Peat or turfy loam in equal parts and plenty of sand is the best, but either peat or loam may be used separately if more convenient, always adding plenty of coarse silver sand or river sand.

New Geranium.—*C. Doe.*—We fear your Geranium is far behind (from a florist's point of view) many kinds in the same way already in commerce.

Double Mimulus.—*J. W. F.*—The flower sent is what is termed a Hose-in-hose. Such freaks occur in Primroses, Gloxinias, &c. It is worth cultivating.

Sweet Williams.—*Glasgow.*—We should not call the flowers of Sweet William sweetly scented.

Buds Falling off Fuchsias.—*Glasgow.*—Too little air and too much or too little water will cause this

Names of Plants.—*Gaston.*—We cannot name a plant from a mere description; send us flowers and leaves, and no doubt we can name it.——*E. C.*—Mitrana coccinea.——*May.*—1, Adiantum Capillus Veneris; 2, Platyloma rotundifolia; 3, a variety of common Phlox; 4, Sedum spathulifolium variegatum; 5, Tradescantia virginica; 6, Selaginella Kraussiana.——*St. R. E.*—1, Hemerocallis Dumortieri; 2, Aconitum Napellus; 3, Fumaria muralis.——*Wildflower.*—Whitlow Pepperwort (Lepidium Draba).——*Monaghan.*—Common Yellow Rattle (Rhinanthus minor).——*T. E. J.*—We cannot name plants from single leaves.

QUERIES.

2442.—**Cultivating Indian Plants.**—Can any one give me directions for the growth of the following Indian plants which I have raised from seed—Bixa orellana, Clitoria, Bauhinia, Asparagus racemosus, Acacia glauca? Which, if any, are stove plants?—B.

2443.—**Peat Charcoal for Celery.**—Can any one tell me whether peat charcoal is a good thing for Celery, and how it should be used, and what quantity should be given?—NOVICE.

2444.—**Irises from Morocco.**—What should I do with some Iris bulbs imported from Morocco this spring? They were dug up after flowering in the month of April, and have since been out of the ground. In Morocco they flower in the winter and rest in the summer, and prefer moist ground.

2445.—**Skeleton Leaves.**—Can any of your readers inform me how the skeleton leaves are done like what was exhibited at South Kensington at the late summer flower show?—SKELETON.

2446.—**Cement for Window Boxes.**—Can any one inform me by what means tiles are fastened to wooden boxes for window-sills? I have tried plaster of Paris and Portland cement, but to no purpose; neither adhere to the wood, and but very little to the tiles.—THOS. GRAY.

2447.—**Growing Tobacco.**—Will any reader inform me how to grow Tobacco? and how much I am allowed to grow? and also how to dry it for fumigating purposes?—CONSTANT READER.

2448.—**Treatment of Grevillea robusta.**—I bought a plant of this the other day, and some of the leaves now fall off. It is in a large room where gas is seldom used. I should be glad to know how to treat it; I have no greenhouse, but a large light dry cellar, free from frost, that does for some plants in the winter?—J. K.

2449.—**Insects on White Thorn Hedges.**—My White Thorn hedge, which is 1000 yards long, has been covered for three years with small insects which form webs like the red spider and is now half dead. Can any one suggest a remedy?—E.

2450.—**Slugs, Snails, and Wireworms.**—My garden is infested with these. I have been advised to use paraffin, 1 gill to the gallon. I have also been advised to use salt; I am afraid to injure the crop; I have had two rows of Beans destroyed. Can any reader oblige one in trouble by kindly advising me? I have used both lime and soot; I think the soot has checked them a little.—BOSS.

2451.—**The Currant Caterpillar.**—Can any reader suggest a cure for the Currant Caterpillar, which for the last two years has entirely stripped my Currant bushes, eating all the leaves and destroying the wood so entirely, that the fruit dies and drops off when half ripe?—CATERPILLAR.

2452.—**Gooseberry Caterpillar.**—Will any one kindly tell me what quantity of Hellebore powder (recommended to destroy Gooseberry caterpillars) to put to 1 gallon of water to syringe the trees with? and whether using a poison, the fruit in its present advanced state would be injured in flavour?—CONSTANT READER.

2453.—**Lily of the Valley not Flowering.**—I have read with interest "J. C.'s" note under this head, and wish to ask a question as to situation. Will a border at the foot of the north wall of a house suit the Lily of the Valley? They get a few indirect rays of sun during a portion of the day for say two months of the year. Ought they to be more exposed to sunlight than this? if so, what other plants would flourish on such a border?—LANGLEY HURST.

2454.—**Fuchsias for Greenhouses.**—Will any reader give me the names of six of the best Fuchsias for greenhouse decoration?—DEPOT.

2455.—**Raising Begonias from Seed.**—Can any one tell me an easy way of raising tuberous-rooted Begonias from seed? I have tried and failed several times. I sowed the seed in 6-in. pots in a mixture of leaf mould, sand, and loam, sifted, with plenty of drainage, but the seed did not germinate. The pot was placed in a hotbed, and kept moist and shaded.—MAY.

2456.—**Propagating Wistarias.**—Will some reader tell me the best way and time to propagate Wistarias? also what soil do they require?—GASTON.

2457.—**Elder Trees from Cuttings.**—I struck some cuttings of Elder this spring which flourished well for a time, and then suddenly drooped and died away. What was the probable cause? When I pulled one of them up I found attached to it a curious kind of insect or worm. I often see the same kind of insect under a brick or stone on the surface of the soil.—INEXPERIENCE.

2458.—**Auriculas.**—I shall be obliged to any good authority who will specify the essential and distinctive characteristics indispensable in a perfect flower; and also state the names of the different races or classes, and what is the true dividing line between the alpine and the fancy or show Auriculas.—BERG.

2459.—**Hedges for a Garden.**—Will someone inform me what is the best kind of hedge to grow? and when is the proper time to plant it? I want to divide my garden from my neighbours, and, of course, should prefer a hedge that would grow rapidly; at present I have only a wire fence.—T. H. T.

2460.—**Paralysed Fowls.**—I have a Dorking hen which is very much troubled with paralysis. Could any of your readers inform me of a cure?—SOUTHPORT.

2461.—**Ants in Lawns.**—Can any reader tell me the best way of destroying ants' nests in Grass plots, and if it can be done without killing the Grass? I have hitherto used boiling water, but this of necessity kills the Grass also, and leaves a yellow barren spot all the summer.—JOHN B. C.

Sending Plants by Post.—Sir,—You find I have stopped my advertisement in your paper; I wish to give the reason, and ask for some information. A fortnight since the postmaster of Barnstaple stopped my boxes of Ferns, and would not allow them to go by post. To this I sent a letter to the secretary of the General Post Office, and I enclose his reply. I am at a loss to understand why nurserymen advertise Ferns and plants sent free by post if this is the case. In the "Post Office Guide" (p. 15) there is nothing said about plants. My Ferns are sent in strong cardboard boxes, and packed in dry Moss, and the boxes papered, so that not the least damp can come through. I should be glad to know what others say in this matter.—E. GILL. "General Post Office, London, June 17, 1880. Sir,—In reply to your letter of the 13th instant, I have to inform you that the rules of the department prohibit the transmission by post of live plants, inasmuch as they must necessarily be more or less damp, and must be sent with a certain quantity of mould, and the postmaster of Barnstaple acted rightly, therefore, in stopping the packets to which you refer. In regard to the packets containing live plants which you mention as being frequently sent by other persons, I can only assume that they have passed owing to officers dealing with them failing to detect the nature of their contents.—S. A. BLACKWOOD, Secretary."

THE HOUSEHOLD.

How to Cook Green Peas.—Shell one peck of Peas; fill a saucepan half-full of water with one tablespoonful of salt, four lumps of sugar, and a good-sized bunch of Mint. When the water boils, put the Peas into the saucepan and boil rapidly for fifteen minutes; skim the scum that rises, or the Peas will not be a good colour. Strain the water off into a basin, as it is so useful to make Pea soup. Add 1 oz. of butter; shake the Peas about until the butter dissolves; serve very hot.—J. BAKER.

Peas Flemish Fashion.—We regret that a printer's error occurred in this receipt, as published in GARDENING, June 19. The following is the way it should have read: "For the following receipt we are indebted to Sir Henry Thompson: Put 1 pint of Peas, 1 oz. of butter, and ½ oz. of flour into a stewpan; stir well over the fire until the butter is melted, add a little Parsley, three or four small Onions cut up, and two Lettuces sliced rather fine, and ½ pint of Stock, a teaspoonful of sugar, and some salt. Put on the lid, and stew for half-an-hour. Take out the Parsley, add a little more butter, and serve."

How to Preserve Eggs for Winter Use.—Take ¼ lb. hot lime, slake it; when thoroughly slaked add ½ lb. of salt, 1 oz. cream of tartar, and 1 gallon of spring water; when all is dissolved put in the eggs and cover the jar closely. I have found the eggs thus done in March to be perfectly good for all cooking purposes and poaching the following March.—DOT.

—— To 5 quarts of water put 1 lb. of salt, 1 oz. of saltpetre; boil it ten minutes, and when nearly cold add two tablespoonfuls of quicklime. Let it stand two days, then put in the eggs with the thick end downwards. The eggs must be fresh. The jars should be kept in a cool place and not moved. The above is an excellent recipe.

To Preserve Green Gooseberries.—Top and tail the Gooseberries (which should be scarcely full grown, or at least before they begin to ripen), put them into ordinary wine bottles, shake them down close, and fill up with cold water; then place them in a pewter kettle of cold water nearly up to the neck, as many as the pot will hold to keep them steady; let the water boil, and as it heats you will see the water run over out of the bottles, but you are not to regard this. When you see that the Gooseberries are fairly coddled, they are done sufficiently. Have your corks and sealing-wax ready, and take the bottles one by one out of the boiling water and cork and seal instantly, success all depending by hermetically closing the bottle before its contents have time to cool. After corking, cut off the cork level with the top of the bottle, and drive it with a hammer the eighth of an inch below the top, and fill up well with wax. As has been said, success depends upon hermatically closing the bottles quickly, and when cold you will see a considerable vacuum, and it is this exclusion of air which is the preserving quality. It is desirable to have as open necked bottles as you can reasonably get, both for getting the fruit in and out. Choose the smaller sort of Gooseberries; keep in a cold cellar.

POULTRY.

Hatching Chickens.—With eight hens and a cock, which were hatched in March and April last year, I have had eleven chicks from eleven eggs, and are all doing well and hearty, being three weeks old. The hen was twice off the nest for some hours, and was put in the run with the other fowls. I mention this, as I know some poultry keepers are so timid when the hen is off the nest any length of time. I never interfere or look for the chickens until the time is quite up for them to be hatched, which I find much the best. Years ago I used to take them away as they came out, but consider I do better by letting Nature have her own course. I give the chickens whole groats, and in two days give them liver cooked and chopped fine, which they heartily enjoy, and continue to feed them on the same.—THORBURN.

Prolific Fowls.—I have a hen which was hatched May 19, 1879, which brought out a brood of chickens on April 16 last, and commenced laying again May 24. I have also a half-bred Brahma hen which brought out a brood on March 8 last, began to lay on May 2, and laid continuously for twenty-one days, and is now sitting again.—COLEMAN.

Dropsy in Fowls.—Are Game chickens (Bantam) subject to dropsy? and if so, what is the treatment necessary? I have lost one from a swelling which came on gradually.—Rev. L. A. B.

Preserving Eggs.—I shall feel obliged for information concerning the above. I have a great quantity of eggs, many more than I can use at present. I have been greasing them with pure lard and putting them in bran; but I find they are just beginning to taste unpleasantly of the bran.—A. T. F. [See receipts above.]

Cockerels.—What are considered best—those with single or double combs?—E. E. T.

Cramp in Chickens.—Can any ready tell me what is best for cramp in very young chicks?—A LADY.

Featherless Fowls.—"F. R. C.'s" birds have acquired the habit of feather eating, as described in GARDENING of May 1. Their eggs are quite wholesome.

BEES.

Feeding.—Two pounds of lump sugar to one pint of water just allowed to boil makes an excellent food for bees, keeping them healthy and strong. The advantage of assisting new swarms with a few pounds of syrup is incalculable; it enables the bees to devote all their energies to comb-building, thus providing receptacles for the queen to deposit her eggs, the increased amount of brood strengthening the hive most materially. For this purpose it is necessary to use a bottom feeder, which can be had for a few shillings complete, but in all other cases the writer strongly recommends the Lancashire Feeder. It prevents robbing and fighting, and is in all respects so convenient.

Removal of Hives.—Hives should not be moved during the working season a less distance than two miles, or many bees will return to the old stand and be lost. In case it is required to alter the position of the hive a short distance, this should be done gradually, say one or two feet only per day, letting the entrance to the hive face the spot you are moving it from. SAMUEL YATES, *Manchester*.

How to Keep Bees.—I should be glad if any one could give me some information concerning bees—viz., the best kind of hive; what kind of bees are the best; and also, is there any way of preventing them from swarming in other people's grounds? Our garden is amidst a number of other gardens, but I thought there might be some way of telling when they are going to swarm, and putting another hive ready for them.—W.W.

AQUARIA.

Water in Aquaria.—Would you inform me if there is any way of supplying oxygen to fish in aquarium (having no plants) except by changing the water, as I find I have to change it every day, which is troublesome? Also what is the cause of the scales of the gold fish falling off?—PISCA.

—— The ordinary drinking water will answer well for an aquarium, but river water is best if it can be procured. The water will not want changing for two or three months if "J. T. M." keeps plenty of vegetable life in the tank, and keeps it from the direct rays of the sun.—NEPA.

White Matter on Gold Fish.—Take the gold fish out of the aquarium, and put them into a pail filled with clean water. Get some fine sand and throw it on the fish two or three times a day, and this will clear all the white matter off.—W. C. J.

COVENT GARDEN MARKET.

WHOLESALE PRICES.

Cut Flowers.—*Per dozen bunches.*—Anemone, 2s to 6s; Azalea, 4s to 9s; Cineraria, 6s to 12s; Ferns (various), 3s to 9s; Heliotrope, 6s; Lily of the Valley, 4s to 12s; Lilac, 2s to 8s; Mignonette, 4s to 9s; Narcissus, 6s to 12s; Pelargoniums (zonal), 3s to 6s; Pelargoniums (large flower), 6s to 12s; (double), 6s to 12s; (Rose-scented leaf), 6s; Spiræas, 6s to 12s; Tropæolums, 1s to 3s; Tulips, 4s to 9s: Violets (blue), 1s to 2s.—*Per dozen flowers.*—Abutilon, 4d to 6d; Arum Lilies, 3s; Tree Carnations, 1s 6d to 3s; Eucharis, 4s to 6s; Gardenias, 2s to 8s; Roses, 1s 6d to 6s.—*Per dozen sprays or trusses.*—Bouvardias, 1s 6d to 3s; Fuchsias, 2s to 4s; Primulas (double), 9d to 1s; Stephanotis, 2s 6d to 4s.

Plants in Pots.—*Per doz.*—Arum Lilies, 9s to 12s; Adiantum cuneatum (ordinary), 6s to 18s; Begonias (flowering), 6s to 12s; Begonias (fine-foliaged), 6s to 12s; Bouvardias, 12s to 18s; Cineraria, 4s to 12s; Daphne indica, 4s to 6s; Dracæna (green-leaved kinds), 12s to 30s; Euonymus, 4s to 12s; Euonymus (variegated), 6s to 18s; Ferns (greenhouse and stove, various), 6s to 18s; Ficus elastica, 18s to 60s; Fuchsias, 6s to 12s; Gardenias, 24s to 36s; Lily of the Valley, 12s to 24s; Mignonette, 6s to 9s; Nasturtium, 3s to 6s; Palms (small), 18s to 60s; Pelargoniums (fancy), 9s to 24s; Pelargoniums (scarlet), 4s to 9s; Pelargoniums (double), 6s to 12s; Roses (hybrid perpetual), 12s to 24s; Spiræa japonica, 6s to 18s; Selaginellas, 3s to 4s; Virginian Creepers, 6s.—*Per pair.*—Maiden-hair Ferns (large), 4s to 7s; Palms (large), 15s to 42s; Amaryllis, 1s 6d to 3s each.

Fruit.—Apples (culinary), per bushel and barrel, 9s to 30s; Cobs and Filberts, per 100 lb, 120s; Grapes (English hothouse), per lb, 2s to 6s; Lemons, per box, 30s to 35s; Oranges (various kinds), per 100, 8s to 16s; Pomeloes, per dozen, 3s to 6s; Pine-apples (St. Michaels), each, 5s to 15s; Pine-apples (English hothouse), per lb, 2s to 3s; Strawberries per lb, 9d to 2s; Gooseberries per qt, 3d to 6d.

Vegetables.—*Per* 100.—Asparagus, 3s to 5s; French Beans, 9d to 1s. *Per dozen bunches.*—Carrots (outdoor), 4s to 5s; Watercress, 6d to 8d; Leeks, 1s 6d to 3s; Mint, 4s to 6s; Parsley, 4s; Turnips, 1s to 1s 9d; Radishes, 9d to 1s; Herbs, 2d to 6d. *Per doz. punnets.*—Cress, Mustard, or small salad, 2s. *Per dozen.*—Cucumbers, 4s to 7s; Endive, 2s to 3s; Lettuce, 6d to 1s. *Per bundle.*—Horseradish, 3s to 6s. *Per lb.*—Shallots and Garlic, 6d; New Potatoes, 1d to 3d. Chervil, per punnet, 3d; Corn Salad, per half-sieve, 2s; Mushrooms, per pottle, 1s 3d to 1s 9d; Potatoes (general store, round kinds), per ton, 100s to 200s; Kidney, per ton, 120s to 180s; Parsnips, per tally, 5s to 7s; Rhubarb (per dozen bundles), 2s to 3s; Spinach, per half-bushel, 2s 6d; Tarragon, per bunch, 6d.

REGISTERED FOR TRANSMISSION ABROAD.

THE MONKEY PUZZLE.
(ARAUCARIA IMBRICATA.)

MOST people know this as one of the most ornamental of lawn trees. It will succeed in nearly all parts of England where the situation is dry and the soil suitable, but in low damp situations it frequently gets injured in very cold winters. In small gardens where a little plot of Grass exists this plant would form a suitable object for the centre, and even near towns it would succeed fairly well if properly planted at first and provided with suitable soil. When the soil is not suitable the tree loses its lower branches, and becomes anything but an object of beauty. Turfy loam, such as that cut from the roadsides, mixed with common garden soil, would be excellent for it. A round hole should be dug, say 6 ft. in diameter and 2½ ft. deep; the bottom should then be roughly turned over and a little brick rubbish or similar material be mixed with it to act as drainage. A little of the coarsest loam may then be placed in the form of a cone over the drainage, and on this the plant may be placed, allowing the roots to be laid out evenly all round and in a slightly slanting direction. Place over the roots a little fine soil, which work well in between them with the hand; then fill up the hole, well tread the soil in, give a good soaking with water, place a stout stake to the tree, and tie it with stout woollen material, yarn, or anything that will not cut into the bark of the tree; leave it for a few days and the earth may be turned over, or planted with plants, or sown with annuals as desired. The great point is to secure thorough drainage, for without this the roots get injured in winter, and the tree soon begins to decline. We have known fine trees of this Araucaria in a garden within a few miles of London, which, owing to being planted on a badly-drained lawn, although the soil was good, succumbed to the heavy rains and severe frosts of winter; whilst other trees in the same garden, which had been planted in a bed of soil in the centre of a grand walk continued fresh and healthy, and grew with great vigour. This shows that the drainage afforded by the gravel walk was instrumental in saving the trees. Perhaps there is no other tree upon which so much money has been wasted as in the case of the Araucaria. Most people have desired to possess it, whether their gardens were suited to it or not, and, without any preparation having been made in the way of soil or drainage, the trees have been planted, and the results have been disappointment and loss. The annexed illustration, taken from the living plant at Dropmore, shows to what a magnificent tree the Araucaria will grow when the climate, soil, &c., are suited to its requirements.

THE MONKEY PUZZLE (ARAUCARIA IMBRICATA) IN THE GARDENS AT DROPMORE

Hardy Edging Plants.—In the immediate neighbourhood of buildings it is sometimes desirable to cover certain places with some permanent living carpet, especially in positions where Grass cannot be got to grow satisfactorily, or where it is difficult to keep it in good condition by means of the mowing machine or scythe. Areas surrounded by stone kerbing and its usual adjuncts are difficult to mow, and where the necessary operations of clipping has to be performed with shears, other subjects might be substituted for Grass that would have a good appearance at all seasons, and that would require less labour. We have some narrow borders enclosed with massive stone kerbing, and the majority of these are planted with Irish Ivy, pegged down close until well established, when the only attention which it requires is clipping over occasionally, and the beautiful, fresh, green

groundwork which the young foliage presents can scarcely be surpassed by any plant with which I am acquainted. When the borders are wide enough to admit of its being done, a space is left in the centre for brightly-coloured flowers, which the Ivy shows off to great advantage, and in spring a beautiful effect is produced by large masses of Snowdrops peeping through the foliage of the Ivy. These were planted with the Ivy, and have been allowed to remain undisturbed for years. Large specimens of Hydrangea and similar plants have an excellent effect plunged in this kind of border during summer, and replaced by Thuja aurea or Golden Yews in winter; in fact, any number of variations may be worked out on this simple but effective groundwork. As a good contrast to the above we have planted some panels with Golden Honeysuckle (Lonicera aurea reticulata), and treated it in every way like the Ivy. It is a charming subject, and in such positions is better variegated than on pillars or arches, as there is always an abundance of small spray-like shoots with the freshest and most effectively-marked variegation, induced by the frequent pinching and clipping to which it has to be subjected. On some very shallow panels, where the kerbing is only 2 in. or 3 in. high, I have found the different varieties of Sedums or Stonecrops most effective as groundwork, as, though only planted thinly at first, they quickly form an even unbroken mass, and they have this advantage, that they will grow in shallow, dry soils where little else will succeed.—J. G.

GARDEN ORNAMENTS.

GARDENS can be made to wear a very beautiful appearance by the addition of a few ornaments in which flowers can be grown, and may be accomplished by any amateur gardener at a very trifling cost. For instance, a vase may be made by purchasing a shallow wooden washing tub, which may be procured at a cost as low as a shilling, and in the bottom, by means of an auger, bore about a dozen holes for drainage, and screw the tub in the centre to either a round or square piece of wood about 3½ ft. in length, which will serve as a pillar. On this pillar Virgin cork can be nailed or glued, leaving 1 ft. or more for insertion in the ground. Procure a number of Willow or Nut sticks quite 1 in. in thickness, strip them of their green covering, lay them in the sun, and when thoroughly dry split them down the middle; cut into lengths of 2 in. longer than the depth of the vase and point them at each end; nail or glue them to the sides of it, close together the whole of the way round, allowing the points to be 1 in. higher than the top edge of the vase itself. Paint the whole, except the cork, a moderately deep green, give it a coat of varnish, and when dry insert it on the spot where it is intended to stand. To some this may not be very pleasing, on account of the common appearance of the article; but I have seen them made in this manner, and was very much struck with the idea, and which indeed was a very agreeable improvement, although the garden in which they stood was tastefully and prettily arranged before their admission. Strew the bottom with potsherds, cinders, stones, or anything that will secure drainage, then fill up with mould. Should the latter require manuring, mix it either with horse or sheep manure. If the latter is obtainable a small quantity will suffice, being considered as much richer and stronger than the other. A Fern, Fuchsia, or Geranium will make a centre plant, and around it, circle within circle, Virginian Stock, Lobelia, Pyrethrum, and Daisies, or other small bordering plants, according to the discretion of the operator, and he will doubtless in due time be rewarded with a splendid vase of flowers at a small outlay. With a few pieces of ordinary ½-in. deal board almost any shape may be constructed and finished in the same manner. Another way: procure a large flower-pot, and around it, by means of good Portland cement, fasten a quantity of cockle or whelk shells, which may be purchased at a fish shop at an exceedingly cheap rate. Thoroughly soak and cleanse them in boiling water or soap-suds, then wash in cold water; plaster the sides of the pot with cement, and apply the shells to it whilst wet. A stand in the shape of a long single-legged table could be made for it, the top being a trifle larger than the bottom of the pot, and paint it the same colour as in the previous case. Follow the same directions with regard to drainage, mould, &c. Dwarf Nasturtiums look exceedingly handsome in a vase of this description. A Fern or Geranium will look equally attractive if encircled with a bordering plant, or creepers could be trained to hang over its edges. These ornaments are simple enough to make and in no way expensive; the cost in either case would amount to very little over a shilling, and many an unsightly corner in a garden could be filled up with one or more of these contrivances.

NEWT.

VEGETABLES.

Planting Asparagus.—I have invariably found Asparagus to succeed best if removed while in active growth, even as late as July. I have never known one-year seedlings to fail, and I have never known perfect success to attend the removal of older plants. Many object to the loss of time caused by planting one-year-old seedlings. To overcome this difficulty, I manure the ground very highly on which the seed is to be sown. It is sown in rows 1 ft. apart, and the young plants are thinned out to 4 in. or 5 in. asunder, by which means I obtain better roots than ordinary two-year-old plants, and from these some heads may be cut twelve months after planting.—R. S.

Second Crop of Hearts from Cabbages.—I speak from experiment and practice when I say that if the good sound leaves are left on Cabbage stumps, a second crop of three or four small sound hearts will speedily be produced as close to the stem of the plant nearly as the original heart. Whatever is produced fit for table from plants trimmed to mere stumps will be, at the ends of long branches, mere open bunches of whitish leaves, and ridiculously small as compared with the size of the plant, the length of time required, the exhaustion of the soil, or with the compact and handsome produce of untrimmed plants. In a word, a second crop from plants is one of hearts; a second crop from stumps is leaves and branches—out of place in a garden. I have heard some people say that their Cabbages cost them 1s. each, and would suggest in a general way a reduction per head to 6d. each by growing half the quantity on half the ground; to 3d. each by growing a second crop of hearts by proper treatment; and to a 1d. each by clearing them off in time for a successional crop of some other vegetable.—J. M. T.

Growing Turnips.—Turnips sown in May and June should in most localities be located in as cool and moderately shaded a position as possible, as a period of drought is frequently destructive to midsummer crops in fully exposed situations. The main crops, intended for autumn and winter use, which are the largest and most important, should be made from the beginning of July until the middle of August, according to locality; and a small sowing may be made at the end of August for spring use, as the smallest roots stand the winter best, and come in very serviceably before spring-sown crops are ready in any quantity. If the weather be moist and showery at the date of sowing, the seed quickly vegetates, and attention should immediately be paid to keep the young plants growing quickly by means of watering, surface-stirring, and dusting with lime, soot, or wood-ashes, to keep off insect attacks; for if growth be arrested, the roots are invariably hard and stringy. When watering is necessary, only rain or pond water should be used, of equal or higher temperature than the atmosphere, as cold spring water rather checks than encourages growth. As regards storing the crop, this need only be practised a provision against prolonged periods of sev weather; for, however carefully they may stored away, some deterioration of flavour tal place. A good plan is to lay the finest roots rows, well covering them with soil, and leavi the whole of the foliage on, which forms a c siderable amount of protection, and is eas supplemented in case of severe frost. Of cou they should be in a position easily accessil Before growth commences in spring the remn of the crop should be pulled up and stored the coolest available position. The very lat sown crops of half-grown roots will prolong supply until the earliest spring-sown crops fit for use. In dry soils Turnips are often, hot seasons, not only of inferior quality, but is also difficult to get the seeds to germin freely and regularly, and to induce the you plants to make a sufficiently rapid growth escape the ravages of the fly. Where a pi of cool-bottomed land that has been w manured and deeply dug in the previous autu or early winter can be reserved for the m crop, the chances of obtaining good succul roots are pretty well secured. But if, as quently happens, the Turnip crop has to succ another crop only just cleared off, the follow is probably the best plan to secure good pla and induce a rapid growth: After the land been manured with thoroughly decayed man and dug over (it is a bad plan to dig long man into land that parts with its moisture rapi any time during the spring and summer), spr on the surface a good dressing of burnt earth charred rubbish, and in raking down the surf this will mix well with it, and will not only as a valuable manure, especially suitable Turnips, but will also tend to retain the m ture in the land. By a little forethought in periodical clearings of the rubbish-yard, a h of this kind of material can always be held reserve for such emergencies. After the l has been thus prepared, wait for a shower, possible, before sowing the seed. If this can be done, sow in drills, drawing the drills rat deeper than would be necessary for early cr so as to lay the seeds in the moist soil whic generally found under the surface if the land lain two or three weeks after being worked consolidate. If the weather continue hot dry, shade, in order to assist the land to ret its moisture, which is done in the following w and this not only keeps the soil comparativ cool, but also keeps small birds from pulling plants up as fast as they appear, in order to at the seed. If, then, the weather be dry hot, and the seeds do not germinate quickly number of short forked sticks, pushed into bed at intervals of 3 ft. or 4 ft., and over th suspended one or more lengths, as may be nec sary, of netting, may be employed. It is k about 1 ft. from the ground on all sides; th is thus a continual circulation of air. But ground, being shaded from the hot sun, reta its moisture, the seeds vegetate strongly rapidly, and, as soon as the plants are fairly the nets are removed and the hoe used regular There is nothing like a frequently-stirred s face to encourage rapid growth, and ra growth is essential to mild flavour in vegetab As regards varieties, Early White Dutch v formerly almost universally grown for earliest crop, but it is superseded by variet that continue fit for table longer. It is, h ever, a very useful variety, either for the v earliest or for the latest crops. Early Wh Strap-leaf is an excellent rapid-growing varie with small crown of long strap-shaped leav Early Six Weeks, a rapid growing variety, g for summer use; Red American Stone, a medi sized variety, skin dark when exposed, fl clear, white, and firm; Cattell's Silver B round, white, excellent variety; Early Snowb good for general crop; Green Top, Six Wee round, white, hardy, and good; Orange Je or Golden Stone, a Cheshire variety of handso form and excellent quality, and, when the col is not objected to, should be largely grown main crop. Chirk Castle Black Stone is, haps, the hardiest and best variety for win use, especially in cold localities; for, altho the skin is black, the flesh is white as snow, of excellent quality. There are other equa good and useful varieties, but a selection of f or five really good kinds that are found to the locality are sufficient or the larg garden.

Mustard and Cress on Flannel.—A very interesting way to grow Mustard and Cress on flannel is to sew a piece of flannel on a glass bottle of any shape, wet the flannel thoroughly, and roll the bottle in the seed till it is covered; fill the bottle with water, and keep it full. When the flannel requires watering, pour the water in the mouth of the bottle, and it will look very pretty in about a week or ten days.—C. S.

How to Reduce Bones.—It frequently happens in country places, where bones are plentiful, that there are no mills to grind them, and if applied to the land as they are, they decompose so slowly, as to be of comparatively little use. In such cases, chemical means, which are always at hand, are to be brought into requisition. Of all the various means that can be employed for decomposing and dissolving bones, the best and most practicable is wood-ashes. They are generally plentiful in country places—they prevent any unpleasant odour from being given off, and, above all, cause a rapid and complete decomposition. The bones are converted into a fine powder, which, mixed with the ashes, furnishes an excellent fertiliser, rich in potash and phosphoric acid. The method of using them is as follows:—A trench 3 ft. or 4 ft. deep, and of any desired length, is dug in the earth and filled with alternate layers of ashes and whole bones, each layer being about 6 in. thick. The lowest as well as the top layers are of ashes, and each layer of ashes is thoroughly saturated with water. At distances of 3 ft. poles are rammed down to the bottom of the ditch, and every eight or ten days they are taken out and enough water poured in the holes to saturate the ashes. At the end of two months the whole heap is thoroughly stirred up with a fork, so as to mix the ashes and soften the bones, which are then left to ferment again, water being added as often as necessary. In about three months more, the heap being worked over twice or three times, the decomposition of the bones will be so complete, that only a few of the largest remain, and these are taken out and put in another heap. This method of using bones comes to us from Russia, and is very highly recommended. The action of this fertiliser upon crops is said to be something extraordinary. It seems as if the salts in the bones and those in the ashes unite to form very soluble salts, which can be at once assimilated by the roots of plants. Where wood-ashes are scarce, recourse must be had to horse manure. The bones are soaked a few days in water, and then placed in rectangular pits with alternate layers of horse manure, each layer being drenched with the water in which the bones were soaked. The strata of bones are 3 in. thick, and those of manure 1 ft. thick. The pit is covered with earth, so as to be tightly closed. The decomposition of the bones will require in this case about ten months, when the mixture is ready for use as a fertiliser. They may also be more speedily prepared by boiling in the following manner:—Mix them in a large vessel with wood-ashes, and, to make the ashes caustic, add about a peck of fresh lime to each barrel of bones. Saturate and cover the ashes well with water, and then apply heat for, say, twenty-four hours, or during the day for two successive days. All the bones by this time, except the very hardest parts, will be so reduced, as to be easily pulverised, being in a pasty condition, suitable for placing in layers in making the compost heap. Another day's boiling will reduce the remainder of the hard bones. It is useless to recommend converting them into home-made super-phosphate by using sulphuric acid; the difficulty and trouble in procuring the acid away from cities, and the care and experience required to use it, are sufficient objections.

An Easy Method of Catching Snails in Gardens.—Any one troubled with snails in their gardens should get two or three Oranges and take the peel off whole and cut it in halves, laying them on the beds at night. In the morning examine the Orange peel; shake off the snails and kill them, and put the Orange peel back again on the beds to catch some more. A few trials of the above will soon clear a garden of snails. The same simple remedy can be applied with success in Cucumber and other frames and greenhouses where snails are to be seen.—C. J. Wraith.

EXHIBITION AT SOUTH KENSINGTON.

The Pelargonium Society held its annual show at South Kensington on Tuesday last. The plants were, on the whole, equal to those shown in former years, whilst the varieties shown were a great improvement on those seen a few years back. The prizes for vegetables offered by Messrs. Sutton & Sons, and Messrs. Carter & Co., and Messrs. Webb & Sons brought together a fine display of the best vegetables we have seen exhibited for some years past—that, is at this season of the year. The Peas and Beans were remarkable examples of good culture. Carter's Telegraph is an excellent Pea, having as many as ten large Peas in a pod; whilst Sutton's Improved Long-pod Bean is the finest exhibition Bean we have ever met with. The pods are at least 12 in. long, and contain seven or eight large and handsome beans. The Nantes Horn Carrot is a kind well worth the notice of our readers. It can be grown in much shallower ground than the kinds usually grown in gardens, whilst in point of flavour it is infinitely better than any other kind, the Early French Horn excepting. All-the-Year-Round Cabbage Lettuce, too, should be grown by occupiers of small gardens. It takes up comparatively little room, and forms plump balls of delicate leaves, which are much superior to those of the coarse Cos Lettuces. It, of course, requires no tying to blanch, which is a great saving of time. The prizes for the best packed fruit offered by Messrs. Webber & Co., of Covent Garden, were not so well contested for as we expected. The first prize lot were packed as follows:—Grapes—A layer of dry Moss was put into a box, some being also packed round the sides to leave a hollow in the centre. A large sheet of tissue-paper was then placed in this hollow, into which the bunches of Grapes were put as close as possible point downwards. The sides were then packed tightly with dry Moss. So firm were the bunches packed, that they could not be removed until the Moss surrounding them had been loosened, and yet they were perfect, scarcely any of the bloom being injured. The Peaches were wrapped in tissue-paper, and then packed firmly in wadding in shallow boxes. The Strawberries were packed in layers in shallow boxes, with soft leaves intervening between each fruit.

Mr. Cannell, of Swanley, made a remarkably fine display of tuberous Begonias. Roses were neither numerous nor of first-rate quality.

House and Window Gardening.

WINDOW GARDENING.

Making and Planting a Fern Case.—In a recent number (49) of Gardening Illustrated I gave my experience of one part of window case management, and though the remarks I made then may have deterred some from embarking in this popular style of amateur gardening, there is really no reason why any one who has a taste this way should not have at least a few plants which, with a very little trouble, may be grown as well as they could be in much larger places. There is much to be said in favour of window cases—their utility in hiding unsightly views, &c.; and there is no class of gardening anything like so suitable for those who live in towns. The principal thing is to get the right class of plants, and for cases nothing is so good as Ferns. Of course, where the owner of a case happens to have a frame or greenhouse, or even chooses to buy plants from some nurseryman from time to time, it is possible to have a variety of foliage and flowering plants; but where, as is most often the case, the area is limited to the one solitary window case, and the owner cannot afford to buy plants again and again, nothing does so well as Ferns; they are all amenable to nearly the same condition of culture, and they stand neglect and ill-treatment better and longer than any other class of plants. I myself have done much in this way under by no means favourable circumstances, and it is even less than some of my friends have done. My case is made on the most economical scale, and my *modus operandi* of planting was as follows:—I first covered the sides and bottom with a good coating of Portland cement, and then having procured some pieces of tufa I proceeded to make my rockwork. This, of course, can be arranged to suit tastes. All that is required is to first fasten a few pieces to the floor and sides and then build from them. The Portland cement should be made thin, and then if the pieces of tufa are dipped in it and supported with bits of wood until the cement sets it will become as firm as a rock. The rockwork finished, with a brace and bit I made some ten or twelve holes for drainage; these holes I covered with bits of broken flower-pots to keep the soil out. I then put in some 2 in. of drainage consisting of broken flower-pots and such things, and then having procured some nice sods I broke them up into small pieces about the size of an egg. These I put on the drainage and then filled up the bottom with the compost, consisting of one part good peat and two parts nice light loam, with sufficient sand to give it a light grey appearance. My Ferns are all planted out, and have a bright healthy look that is positively refreshing. My collection consists of the following, viz., Scolopendrium vulgare var. crispum, S. vulgare var. laceratum and cornutum, Polypodium vulgare var. cambricum and pulcherrimum, Polystichum aculeatum, P. angulare var. Bayliæ, Athyrium Filix-Fœmina var. Craigi, var. Simpsoni, and var. Gloveri, Onoclea sensibilis, Cyrtomium caryotideum, Platycerium alcicorne, Adiantum pedatum, A. tinctum, Polystichum acrostichoides, Davallia pyridata, D. dissecta, Nephrodium molle and Pteris serrulata; and for Creepers, Ivy and Japanese Honeysuckle. Y. Z.

German Iris.—These have for some time past been flowering freely in cottage gardens, on

German Iris (I. germanica).

railway banks, and in shrubbery borders. Seeing that the common kinds will grow almost anywhere, it is to be regretted that the finer kinds are not introduced in such a way that a variety, as well as a succession of blossoms which rival those of some of the showiest Orchids, might be obtained. The present is a good time to visit hardy plant nurseries with a view of selecting the best kinds.

Pot Marigold Meteor.—It is gratifying to find that this very charming Marigold is being exactly reproduced by seedling plants. One good feature is seen in the comparative variation of the markings, the orange edging on the lemon ground varying in body, and thus producing a pleasing distinctiveness. It is difficult to say which are the prettiest—it is rather a matter of taste; but those in which the orange predominates are perhaps the most striking. This pretty Marigold is so hardy and suitable for cottage garden culture, that it will soon become as widely grown as Stocks and Wallflowers. Last season was everywhere so bad for seeds, that vast quantities refused to germinate, and doubtless to that must I attribute the fact that out of a 1s. 6d. packet of Continental seed only two plants grew.—A. D.

Bedding Pansies.—Although Pansies and Violas are such useful flowers for the production of masses of bloom in spring, their best effects are rarely seen except when found in large clumps that have been left untouched from the preceding year. Such clumps, however, cannot be had under the present system of bedding arrangements, as in that case considerable division is necessary. Many kinds of what are

known as bedding Violas produce but a meagre appearance in the form of small plants; but clumps that have a score of blooms upon them expanded at once are most beautiful and singularly effective. Just now the fine old Cliveden Purple Pansy is really superb; clumps of great size and full of bloom give a hue of colour such as no other hardy border flower can equal. The pretty mauve Princess Teck and Lilacina Violas in large clumps are truly lovely, and the same may be said of all others, whether white, yellow, or blue. It is not too much to say of the Pansy family that it constitutes in the spring the gayest and most effective of all border plants, and, perhaps, next to the Primrose, the most highly appreciated. Of course, large clumps must be divided sometimes, or else they would become weak and ragged. The best time to do this is as soon as the bulk of the bloom is over, when the clumps should be lifted, pulled into some half dozen or more separate pieces, and be replanted in a cool border for the summer, and kept well watered. These will by October make fine heads of foliage, and can be then planted in beds or borders as desired.—A. D.

Michaelmas Daisies as Flower Sticks.—It may not generally be known how very useful the old stems are for this purpose either in or out-of-doors. The stronger ones will last through the flowering season of most plants, and the very weakly-grown ones are the very things to support a bloom for a week or two, while their colour renders them inconspicuous. The best plan is to cut them down at the end of autumn, strip off the leaves, and tie them straight in bundles and put them in a dry place. If only for this purpose they are worth growing.—J. B.

The Corn Marigold.—Chrysanthemum segetum, or Corn Marigold, a cornfield weed, probably of Mediterranean origin, but now common all over Europe, except the extreme north, is a showy and welcome novelty in our greenhouses in the early spring. At that season flowering plants of the same type are rare. If plants of it are lifted from the open ground in August and placed under glass, they will flower freely, and, on account of their bright colour, prove good acquisitions to our stock of flowers at a period when other things are scarce.

White Azaleas Out-of-doors.—Several bushes of these grow here in the open air that have evidently been out some years. I hope to make an experimental bed of various kinds next spring, as I see no reason why many other Indian Azaleas might not succeed out-of-doors besides the white one, seeing that Camellias grow well here as single bushes on Grass, and are in spring covered with buds in various stages of development.—J. G., *Maidstone.*

The Snowdrop Anemone.—Most of the Windflowers are beautiful, but this is one of the best, as it is comparatively dwarf and very free as regards flowering, its pure white blossoms being as large as a crown piece when fully blown, and drooping gracefully when in bud. The foliage is elegantly cut into narrow segments, and is hairy underneath. This Windflower is a capital plant for the ordinary flower border, the lower parts of the rockery, or the margins of shrubberies, by the sides of woodland walks, in the wild garden, in all situations being quite indifferent as to the nature of the soil, provided it be not too dry. It comes from the groves and from hedgerows in many parts of South and Central Europe, where it presents a showy appearance during early summer. It is called the Snowdrop Anemone on account of its pure white, drooping buds having a resemblance to those of the Snowdrop in spring. Its botanical name is Anemone sylvestris. An illustration of the plant in flower is given on the opposite page.

Aubrietias.—These last long in flower, delight in open, dry, exposed situations, and produce charming masses of warm-coloured blossoms. There are many varieties of Aubrietias, all of which are beautiful, but none more so than A. Hendersoni. The oldest variety is the one shown in the accompanying engraving, Aubrietia purpurea, a pretty flower enough, but thrown into the shade by some of the other kinds. There is a well-known variegated variety of this not of much value, except as a neat little rock plant. Then there is what is called deltoidea, which is very near, if not identical with purpurea. We have also grandiflora, a kind similar in colour to purpurea, but twice or thrice its size. This has a lax, diffuse habit, which makes it a charming rock plant. There is a variety of this called græca, a fine plant, opening out at first a full purple, and dying off a lavender colour. Masses of this, with its various shades of colour, are very pleasing. There is also a fine variegated large-flowered form of it. The last of the Aubrietias I shall notice is Mooreana. Mooreana is a compact little cushion-like plant, which, in its flowering season, is literally smothered with bloom. It is the loveliest of Aubrietias, well adapted for spring gardening purposes, being charming either in masses or as edgings to beds of other plants, perfectly hardy, and will flower from March until June. Some find Aubrietias difficult to propagate; my practice is to pull off all the straggling side-shoots in June or July from the old plants, securing as much stem as possible, and breaking it off close to the main root; then a piece of ground is dug in a cool, shady border, into which is worked plenty of rough sand and leaf-mould; the shoots are then planted in lines, a little sandy soil being placed about the portion put into the ground, and all is trodden down firmly. The cuttings are then occasionally sprinkled and kept shaded from the sun, and, thus managed, but few failures occur. One great advantage in getting the cuttings started

The Purple Aubrietia (A. purpurea).

now is, that the plants become strong and dense by the end of the summer, and are well fitted for planting out.—F. W.

FRUIT.

Caterpillars on Gooseberry Trees.—I planted some young fruit trees in early spring, and have been much troubled by the small caterpillar infesting the Gooseberry trees. Doubtless some readers of GARDENING who have so complained of the ravages of this little pest will be glad to learn a remedy which I was fortunate enough to try, after so many fruitless attempts, has proved successful. It is a vegetable composition in the shape of a powder. I applied it after rain, when very calm, from a small tin canister with holes pierced in the lid. The effect was marvellous; they at once loosed their hold from the leaves, falling on the ground. I then shook the tree by tapping the stock. I then sprinkled a little on the ground under the tree to make sure of them all having a dose, and many scarcely seemed to move after. Next morning I looked to see if it had done them good; I found two or three had escaped untouched under a leaf or two, which I picked off, and gave a little more, finishing, I really believe, the lot, for which I am indeed thankful. I next tried it on the green fly, which infest Rose trees. Pinching off a few leaves from a Plum tree which were covered with the fly, I sprinkled a little over them, which was just as effectual as that applied to the Gooseberry, but I should think it would be more effectively applied to Rose trees from a puff or an india-rubber ball with a thin tube to it about 4 in. long, to blow well into the shoots, but I find the little tin canister pierced with holes in the lid does very well.—H. S.

Watering Fruit Trees.—This is a matter which requires more attention than it generally receives. Figs, Vines, dwarf Peaches, and Plums, and other fruit trees grown in pots and otherwise all want abundant waterings during their season of growth. My pot Vines, after they are fairly in leaf, are watered every day, though the pots are plunged, and sometimes twice a day in dry weather. Not long ago I finished cutting a heavy crop of excellent fruit from a house of these, and up to the time when the last bunch was cut the water was poured on to the soil through a wide-spouted can in floods. The drainage is ample, and I never allow the surface to become dry. My young pot Vines, struck from eyes in spring, receive the same treatment. Shutting up with a steaming atmosphere is avoided, as a certain cause of warty leaves, but at the root the water is supplied unstintingly. Some of my Figs, large bushes in large pots, which are packed with their roots, receive each 5 or 6 gals. daily, and would take more sometimes if I had time to give it to them. They had ripened their first crops of fruit, and are heavily laden with the second, and their ability to carry all through successfully will depend almost wholly on the liberal use of the watering-pot. It is not from want of liquid manure that many plants appear starved, but from want of water simply and nothing more. The amount of feeding material contained in a pot of good soil is almost or quite sufficient for a plant without any additional stimulant, provided it is diluted judiciously and enough. In the matter of Vine borders, for example, the most important and real lesson which has been learned of late years is that we can hardly over-water them if they are ordinarily well drained. Water in more than sufficient quantity at the roots of the Vines is now recognised as a chief agent in the protection of good Grapes; and results have proved that this recognition is correct. So it is with Peaches and other stone fruits grown under glass. The amount of moisture a large and healthy Peach tree will imbibe in a day is enormous. The tree may be compared to a sheet of moist blotting-paper exposed to the sun; it would dry completely in an hour or so. What, then, must be the amount of evaporation from a Peach tree placed against a warm wall covered with glass? In the case of a hard and well-drained border, and a healthy tree thinly trained and protected with glass, I believe it is hardly possible to overdo the watering during the summer season. It may be asserted that the best results have not yet been attained, even in Peach culture. It has been shown beyond a doubt that the grossest Peach shoots can be perfectly matured in this country with artificial aid, and it has still to be proved what can be accomplished by the extension system of training and liberal feeding and watering such as the Vine has been subjected to. Take the Strawberry again; it does not like being treated like an aquatic, as pot plants sometimes are; but a well-drained Strawberry quarter should be deluged with water throughout the summer season, and also mulched, whether we have regard to present or future crops. A droughty June and July ill suits the Strawberry, and liberal waterings alone, under such circumstances, will nearly double the weight of crop. I have, as a rule, always light crops of Strawberries when I have a light hay crop, and both are due to the same cause—want of sufficient moisture at the root.—C.

Hints on Strawberry Culture.—In the culture of Strawberries the best results will generally be obtained where the soil has been trenched or deeply dug and enriched with plenty of good rotten manure; and the beds or rows are not profitable when allowed to remain longer than three years on the same soil. A good strong loamy soil is the most suitable for the plant, but as this is not found in every garden, a mixture of stronger soil can be added to a light soil where good crops of Strawberries are a desideratum. Plants of Strawberries which have been forced in pots will, if planted out in a rich sandy soil, produce excellent crops, for the ball of strong soil at their roots will make them bear well for at least two years after being planted out. I raise all my best crops from pot plants when planted out as early as possible after the fruit is gathered. In

general the plants, after forcing, are huddled together, and often neglected in dry weather as regards water, and not planted out till the pots are wanted again for the newly-laid young batch of runners. This does not give the old plants so good a chance of rooting into the new soil as when they are planted out early. When the weather is favourable in autumn, some of the varieties, when planted out early from pots, produce good second crops of fruit. In planting young plantations of Strawberries from runners, they will be found to succeed best when planted in July or August, for then they have time to root well before the winter sets in: and if the runners have been strong when planted, they will produce some fine fruit the year following. When the planting of the runners is delayed till the spring, dry weather often prevails in March or April before the roots have progressed much, and a year is lost as regards getting much fruit from them. Late autumn planting is, likewise, wrong in practice, for the early frosts heave the plants out of the ground unless well protected with litter. I find that a top-dressing of litter put on in the autumn as a protection against severe winter frosts is requisite for Strawberry beds, whether newly planted or not. In the spring the young leaves grow through it, and the strawy litter keeps the fruit clean after the heavy rains or showers. This is better than using tan, short Grass, or haye, for this purpose, as seeds are shed in the ground, and take labour to eradicate them again. In dry summers Strawberry plants, when swelling their fruits, will enjoy any amount of liquid manure.—W. T.

OUTDOOR PEACH CULTURE.

Summers like the last bring out markedly the advantages which follow attentive cultivation in regard to such fruits as the Peach when grown on open walls, and which, taken collectively, as seen in the majority of gardens throughout the country, I always consider receives the most indifferent treatment that is given to any of our cultivated fruits. In some places at the present time there is on the trees an excellent crop which can now scarcely fail to mature satisfactorily; whilst in others in the same localities, where the conditions as to soil, aspect, climate, and protection to the bloom are the same, the trees are fruitless. Was there not unmistakable evidence of the very different manner in which the trees are from year to year managed, the difference in the crops might be attributed to local causes beyond control. One of the greatest mistakes in the management of Peach trees is the retention of too much wood at the time of thinning the shoots, which, even when laid close in, so as to be fully under the influence of the heat reflected from the surface of the wall, never gets so thoroughly matured (except in the warmest summers) as to give a fair prospect of the bloom being what it should and can be under more favourable conditions. There are those I know who contend that a given amount of frost will kill the bloom whatever its character may be, but this spring the temperature in most parts of the kingdom where Peaches succeed on open walls was not low enough whilst the trees were in bloom to prevent its setting; failure, therefore, evidently arises from the non-ability to produce fruit of the small imperfect flowers, so different in their development from those which are produced where no more shoots are allowed to grow in summer than are needed to afford a crop, and in this way the trees to which I have alluded as bearing satisfactorily are annually managed. It is only natural for cultivators to feel a disposition to keep plenty of young wood to select from at the winter pruning time; but following this course is fatal to success, as the crowding of the young shoots makes it impossible for our insufficient sun power to ripen them properly. To this, and neglect of the trees in letting them get overrun with insects and mildew, clearly may be attributed the failure of very many Peach trees on open walls to give the return which they would render if better treated. Where the first leaves produced in spring are, as is too often the case, allowed to get injured by aphides, so as to cause them to fall off and prevent the earliest efforts of the trees from making wood in a satisfactory manner, the growth made later is necessarily weak, and frequently fails to get matured, unless when the summer and autumn are exceptionally favourable. The result of such conditions is, that the flowers are more or less defective, or wanting in strength and vitality to bear so low a temperature during the blooming season as they would if the wood had been formed under a system of cultivation that would enable its being fully matured. To these causes, and to the roots often not getting nearly so much water as they require, is traceable a good deal of the failures that take place in Peach crops on open walls. A. Z.

CLIMATE AND SOIL.

Like many other men who lead a busy life, I find relief and pleasure in a garden. I would also in passing say a word for the study of botany, which is a never-failing subject of interest to me wherever I go; but my immediate object is to make a few remarks, which will, if not novel, be useful to others in my position. My house stands upon about 4 acres of land, on the north side of a new red sandstone ridge in mid-Cheshire, about 20 miles from the sea, and I use about 1 acre for gardening purposes. The soil is a soft (not sharp or gritty) sand, with rock underneath, and I want to show what I can and cannot grow. When I read the recommendations of various correspondents I feel how useless they are in great measure, for want of a statement of the climate and soil to which they are applicable, and it would be a great help to me if each communication would show where the writer hails from. I constantly find something recommended which I should like to try, but long experience (the gardener's only teacher) has taught me many lessons. For instance, one correspondent gives a glowing account of Tree Pæonies, but neither Tree nor any other Pæonies will grow with me. One of the most beautiful floral displays I ever saw was a collection of Tree Pæonies in a garden near the Severn, but they pine away with me in spite of every preparation of soil which I can make. On the other hand, white and yellow Azaleas and Rhododendrons grow and bloom with me without trouble, the common variety of the former attaining the height of moderate sized fruit trees, and requiring neither peat nor any other preparation. Hollies also grow superbly tall, 15 ft. to 18 ft. high, but Portugal Laurels and Laurustinus, and even common Gorse, are periodically killed in winter. The smooth-leaved Laurel and the Aucuba do not thrive with me at all. The old white Rose forms perfect thickets, yet I cannot grow China Roses, Moss Roses, or any new Roses, except, perhaps, Gloire de Dijon. The common blue Passion-flower and Hydrangeas pine and die, but Clematis Jackmanni grows unprotected and unmanured, flowering wonderfully. Foxgloves, red and white, are a weed, yet Gentiana acaulis and Anemone Honorine Joubert cannot be coaxed to grow, though the common Musk stands the winter and sows itself all over my garden. Sage blooms profusely in perfect health, but Rosemary and Lavender die in the winter. Looking at these facts, it is idle for me to pick out plants from books, and so, doubtless, many others find. Therefore, I ask everyone who writes a gardening article never to omit naming the locality, and, if possible, to describe the soil. Strawberries and Black Currants will not fruit in my soil and red Raspberries get always blighted, but white Raspberries and Red Currants flourish and bear abundantly. Peaches and Apricots mildew and die. White Lilies do not thrive, but Orange Lilies spread all over the place. Of forest trees, Sycamore, Beech, and Acacias find a congenial home, and, being all shallow-rooting trees, do the best. I have four Vines in my oldest house—two Black Hamburghs, a small high-flavoured Black Muscat, and the old sort of Muscat of Alexandria, each, perhaps, twenty years old—growing with the roots all outside in the sand, and nothing to feed them except what they get under a lawn and amongst the shrubs, with no drain anywhere near, and yet I have, after a liberal thinning, on them this summer more than a hundred bunches, some of them (especially the Muscats) fine bunches weighing 2 lb. each. These Vines, which are grown on the two or three rod system, never fail me, and all I do is to put a layer of cow manure on the narrow border every autumn, and to give them often in dry weather a supply of rain water out of the inside greenhouse cistern. I never scrape or dress them, but I keep the house, which is always full of greenhouse plants and Ferns, moist and warm at nights, and give plenty of air (door and lights generally more or less open, except in very cutting winds) during the day. The black Grapes are just beginning to colour now, and the flavour of the Muscats is always much finer than those grown in inside borders possess. I train up new wood every two or three years and cut away the old. One great thing doubtless is that the slope on which my house stands always keeps the soil or sand well drained, and my Grape crop never fails, and I believe that generally too much coddling is practised in Vine growing for table use. I made a great discovery this spring. A strong shoot was broken off one of the Vines accidentally, from which the sap flowed abundantly, but a little plaster of Paris, worked into a paste with the finger on the wound, stopped the bleeding instantly; indeed, the dressing remains on now, and I have ever since used it with invariable success. I will close this long communication by adding that quicklime dusted thickly over the Gooseberry trees with a flour-dredger in dry weather always rids me of my caterpillars, and never harms the trees. Mid-Cheshire.

[We quite agree with our correspondent, that if particulars as to soil and locality were given, communications would be more valuable.]

Snowdrop Anemone (A. sylvestris), a handsome free-flowering hardy plant. (See preceding page.)

Tropæolum compactum coccineum.—The kinds belonging to this section differ from the old Tom Thumb race in being continuous bloomers and in having the flowers well thrown up above the foliage. Plants raised from cuttings produce the most even masses. A few potfuls of cuttings put in at the end of August will give a large number of plants in the spring.—A.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

July 12.—Potting Tree Carnations in stiff soil, pressing them in firmly; potting off seedling Musk plants and Coleus cuttings; sowing a row of Mignonette for supplying cut blooms; also another crop of Endive; planting Cauliflowers and Paris Cos Lettuce; clipping hedges and cutting Laurels; pricking dead flowers and leaves off flower beds, and pegging down such plants as require that attention; thinning Turnips and drawing drills in which to sow Spinach; sowing Snowball and American Strap-leaf Turnips; putting in cuttings of Carnations and Pinks under hand-lights; planting out Wheeler's Imperial and Heartwell Early Marrow Cabbages for autumn use; layering Strawberry runners, three in a bunch, on pieces of turf 6 in. square, for making new plantations; stopping and nailing in the shoots of Tomatoes; looking over Cucumbers and Melons, stopping the shoots at one joint past the fruit, and earthing them up a little where required; mulching late Peas and Beans with well-rotted manure

July 13.—Potting old winter Carnations and staking them neatly; shaking out and repotting old plants of Poinsettias; pulling up Shallots and laying them in the sun to ripen; netting Currant, Cherry, and Gooseberry trees; plunging Chrysanthemums and Cherry trees in pots out-of-doors; sowing a little Chervil for autumn and winter use; also Mustard and Cress; taking up and dividing a quantity of old Polyanthuses; planting out Celery in trenches; getting up early Potatoes and storing them away for seed; hoeing among Gooseberries and Currants, and all other growing crops.

July 14.—Plunging all Roses in open ground, and placing Azaleas out-of-doors to ripen their wood and clear them of thrips; storing away Shallots and Garlic on floor of cool loft, and shading Peaches that are ripe, in order to keep them back; sowing Green Curled and Frazer's Broad-leaved Endive; pricking off herbaceous Calceolarias; also Cinerarias and Primulas; picking off the dead flowers and nailing and tying in Roses on walls; cutting herbs and placing them in an open shed to dry.

July 15.—Sowing Red and White Turnip Radishes; putting in cuttings of different sorts of Pelargoniums; stopping and nailing in the leading shoots of Peaches, Nectarines, and other wall fruit; sticking Peas and getting them earthed up; potting Roses in a mixture of loam, manure, bones, charcoal, and sand; planting May-sown Autumn Giant Cauliflowers on land lately cleared of Peas; leaving the lights of Peach house open day and night where the fruit has all been gathered; also giving abundance of air to all Vines where the Grapes have commenced to colour.

July 16.—Sowing Canadian Wonder Dwarf French Beans; potting on Begonias, Palms, and Dracænas for table plants; earthing up early Celery when the soil is dry and in workable condition; stopping and pegging down Vegetable Marrows, and giving them a good soaking of manure water; looking over Vineries, stopping laterals, and giving all late Vines a good soaking with guano water; potting Strawberry runners; also Coleus and Balsams; sowing Cucumbers for late crops; also Turnips, Radish, and Chervil; planting Green Cos, Bath Cos, and Neapolitan Cabbage Lettuce; also late Celery; putting in cuttings of Hydrangeas, scarlet Pelargoniums, Cytisus, and Coleus; hoeing among Raspberry plants.

July 17.—Potting Mrs. Marshall and Rose of Castile Fuchsias; also Abutilons, Clerodendrons, and repotting young Cyclamens in loam, leaf soil, and sand, afterwards placing them in a cold pit and shading them until well established; sowing Batavian and Green-curled Endive, Hill's Incomparable, and Early Market Cabbage; also Cucumbers for winter supply; digging land in which to plant Wallflowers, and earthing up Cauliflowers and Winter Greens. Giving Peaches and Nectarines a good washing every evening with the garden engine to keep down insects.

Ferns.—Keep a moist atmosphere; water growing plants abundantly, dew them gently overhead with tepid water, but refrain from damping the fronds of Gymnogrammas, Cheilanthes, Maiden hair, and other such Ferns; and repot any that have well filled their pots with roots and that are not already in large pots. Seedling Ferns must be pricked out after they have germinated and can be transferred without difficulty from the seed-pans. Spores, *i.e.*, seeds, should always be sown as soon as they are ripe, and young plants growing on the fronds of Ferns should be separated and treated as ordinary plants, or the fronds containing them may be taken off and layered. Keep a sharp watch over insects of all kinds and remove decaying fronds.

Biennials and Perennials.—Sufficient space in the reserve ground should be now prepared for the reception of the different kinds of biennials and perennials sown some time ago. These, as soon as they are large enough to handle, ought always to be pricked out from 4 in. to 6 in. apart in nursery beds, where they can remain through the winter until spring, at which time they should be finally planted where they are to remain. It is a very common occurrence to see the plants left standing in the seed-bed until they are so weakened by overcrowding as to be of little value. If the soil in which they are to be planted be of a heavy adhesive nature, it must be made lighter by the addition of sand and decomposed vegetable matter, so that the plants when removed in spring will have an abundance of roots, a condition not possible where the ground is close and impervious, but it should not be made rich by the application of manure, as the object is not to induce rank succulent growth, but rather that of a compact character, such as will enable the plants to pass unscathed through the winter, and to suffer little or nothing whatever from the effects of their subsequent removal.

Trees and Shrubs.—Privet, Hawthorn, Holly, Yew, and other hedges may now be pruned with the knife, but where they are not in conspicuous positions that operation may be done with the shears. Evergreen shrubs, and even choice Conifers, are now being pruned into shape with the knife. From Rhododendrons, Magnolias, Azaleas, and other similar things, the beauty of which is over, the old flowers are being removed, and, where time can be spared, the seed-pods also are picked off.

Fruit.

Vines.—Where Grapes are stoning and show the slightest indication to scald, keep the interior of the Vinery in which they are as cool at all times as a greenhouse until the stoning process is over, and not 3 per cent. of the berries will be injured. This scalding, as it is termed, consists in the most prominent berries becoming soft and brown on one side, as if it had been burnt with a hot iron; sometimes a single berry here and there throughout the bunch is affected, and in more severe cases the whole side of the bunch is destroyed. Many a bunch which promised well to begin with has through this been reduced to almost nothing in a short time. A burning sunshine is the chief cause of the disease, for in dull, sunless weather nothing of the kind takes place. When sufficient air cannot be admitted, a temporary shading is often placed over the glass outside to keep down the temperature inside. Midsummer Grapes are colouring fast now, and 1 in. or 2 in. more opening may be left on the ventilators all night with advantage; on mild, wet, dull days the front ventilators should not be kept entirely shut. Be careful to keep the Vines from which all the fruit has been cut perfectly clean from every form of insect. The best eyes from which to raise next year's Vines are those selected from the earliest-ripened wood, and this fact in itself should be sufficient inducement to ensure attention.

Melons.—Melons in frames, &c., will now be growing fast, and must receive every attention in thinning out superfluous shoots, stopping those retained as soon as they reach the sides of the frame; this will cause them to throw out bearing wood. Keep up the necessary warmth in the beds by slight linings; these will not require now to be so heavy as earlier in the season when the weather is cooler, but with late Melons in frames the beds must not be allowed to get cold, or the plants make little progress and the summer is too far advanced before the crop comes to maturity. Woodlice are a great nuisance where they exist in large numbers in Melon pits or frames, and before the fruit begins to ripen measures should be taken for their destruction. They are not at all particular as to their food; slices of raw or boiled Potatoes, or pieces of Apple placed in the bottom of a few small pots and covered with hay or Moss, will attract them in numbers, while by looking over them every morning and destroying, they can be kept down so as to cause little inconvenience. It is only where such precautions are neglected during the advancing stages of the crop that woodlice exist in such numbers as to do serious mischief.

Wall Fruit Trees.—These will require careful attention in trying to keep the legions of aphis and grubs in check. On the care and attention, therefore, now paid to keeping insects down, and the thinning and regulating the young wood, so as to get it well ripened, will depend the success of the crop next year. In addition to handpicking the grubs, the syringe must be used freely on wall trees to try to clear them from filth. The shoots of Peaches and Nectarines should be kept nailed in as they advance, for high winds will do great damage to the young gross-growing trees. Now that the proper amount of wood can be selected for next year's crop, superfluous growths should be removed, and such young shoots as are retained laid in in such a manner as not to shade the fruit. Young shoots of Figs should be loosened from the wall, and Cherries and bush fruits be netted to keep them from birds. If the American blight puts in an appearance on Apple trees, a little soft soap or oil must be rubbed on the parts affected, and if this is done in time, it will effectually stop it from spreading. Thin out the canes of Raspberries where too numerous, and secure them against wind breaking them down.

Vegetables.

Planting Cottager's Kale.—A good space should now be planted with the useful Cottager's Kale, as this is a most excellent vegetable, and so hardy that it will stand even our severest winters. It is much better to have a good breadth of it than to grow several varieties of similar Greens that are not equal to it in any way. Give the plants 20 in. space in the rows, and allow as much between each row.

Vegetable Marrows and Endive.—Thin out Vegetable Marrows sufficiently, not allowing them to get too much crowded, and if the situation be at all exposed, secure the shoots so that they will not be blown about by the wind. See that they are well supplied with water. Wanting this, the plants will not bear to the end of the season. Make a sowing of the Batavian Endive and also of the Green Curled; these will come in as an autumn supply, as the plants from this sowing will not be so liable to run to seed as those sown earlier. Do not put the seed in too thickly, as nearly all of them vegetate, and are not so liable as many to suffer from the ravages of birds or insects.

Cucumbers.—Cucumbers that have been bearing from the commencement of the season and are now falling off a little should have some of their shoots thinned out, and a little fresh soil added to the surface of the bed. In this the shoots will strike root from the joints, where required, by pegging them down. If the plants be clear from insects, thus treated they will again push out growth and fruit freely.

GLASSHOUSES & FRAMES.

HOW TO GROW HERBACEOUS CALCEOLARIAS.

CALCEOLARIAS may be said to consist of two distinct sections—the shrubby and herbaceous—which do not readily blend with each other. The shrubby sorts are well known as useful decorative plants for the flower garden during summer, although they are now less favourably regarded as bedding plants than they have been in times gone by, a circumstance due in a great measure to a difficulty which has in many localities been experienced with respect to their culture. The herbaceous section are seldom used as bedding plants, but are found to be exceedingly useful in greenhouses, conservatories, and even in sitting rooms, in all of which with attention they will continue to be highly ornamental for a period of not less than three or four months. Herbaceous Calceolarias may be readily increased by division, or cuttings inserted in light soil or sand, and placed in a close pit or frame, an operation which should be effected soon after the plants have ceased flowering; but unless it be with the view of increasing unusually meritorious kinds, propagation by this method is seldom resorted to at the present time, as herbaceous Calceolarias can now be raised from seed, and the plants so obtained will be found to possess every good quality that can be desired or expected. A friend of mine at Bury St. Edmunds has for years devoted attention to this section of Calceolarias, and his plants each year are greatly in advance of those of former years. The result has been secured by a judicious system of selection, having reference to the habit of growth, form, texture, and healthy colour of the foliage, as well as the form, colour, size, and markings of the blooms. The foliage is clean and healthy, the flower-stalks stout and robust, carrying abundance of large, well-formed blooms, the markings of which are of the most diversified character, and the colours vary from a straw-white or pale primrose-yellow to the richest crimson-magenta and deep maroon. So distinctly diversified, indeed, are the markings of the flowers, that out of a very extensive collection it was found to be difficult to select two plants whose blooms were in all respects alike.

The seed is sown about the middle of July, and the plants generally commence flowering about the end of April. They are flowered in pots 7 in. or 8 in. in diameter, and when large specimens are desired pots of larger dimensions are used. The seeds of the Calceolarias being exceedingly small, a little care is necessary in sowing as well as in the treatment of the plants during the early stages of development. It is advisable to use for the purpose small seed-pans, or pots some 6 in. in diameter. These should be well drained and filled with light rich soil, which should be pressed moderately firm, placing the rougher portions upon the Moss which should cover the crocks forming the drainage. The surface of the soil should be made perfectly smooth and level, and should then be well watered with a fine-rosed watering-pot. When this has been absorbed, the seeds should be sown upon the wet surface slightly pressed down; and they may have a slight portion of light soil or silver sand dusted upon them. Some growers, however, do not cover with soil at all, but merely cover the surface of the pot with a piece of glass which the rim will prevent from pressing upon the soil. The pot or pan should then be placed in a pit or frame, or under a hand-glass, so that it can be shaded from the sun, or the pot, with its glass covering, may be placed on the north side of a wall, where the seeds will speedily germinate. As soon as the plants are large enough to handle they should be pricked into pans of similar soil, and shaded from intense sunshine; afterwards they should be potted singly into 3-in. pots, from which they may in due time be transferred into pots of some 6 in. or 8 in. in diameter, in which, unless in cases where large specimens are desired, they may be flowered. They should be wintered in a light pit, or on a shelf in a greenhouse as close to the glass as possible; and as Calceolarias are very liable to the attacks of aphides, the structure containing them should be fumigated with Tobacco or good Tobacco paper whenever these pests make their appearance.

The soil used for the final shift may be composed of about two parts turfy loam and one part well-rotted hotbed manure or leaf-soil, with the addition of a portion of silver or other sharp sand, should the loam be of a heavy or tenacious character. D. F.

THE PYRAMIDAL BELL-FLOWER.

(CAMPANULA PYRAMIDALIS.)

Few amongst what may be termed half-forgotten plants are less deserving of neglect than this stately Campanula, which, when well managed, stands a long way at the head of all the family. Its fine proportions, elegant habit, the length of time during which it remains in flower, and the contrast afforded by the white and the blue varieties, are far from all that can be said in its favour, for it is alike adapted to the hall of a mansion or the window of a cottage, the greenhouse or the open ground. It has yet another property of considerable importance—its immunity from insects; for it is rarely, if ever, affected by aphides, red spider, or any other of the numerous pests, the necessity for an incessant war against which does something, especially with amateurs, to mar the pleasure derived from cultivating the majority of plants. Nothing but the disposition that is so prevalent to discard old plants in favour of new ones, regardless of their merits, can account for this Campanula, along with so many other equally well-proved subjects, being so little grown, flowering as it does during the late summer and autumn months, when the majority of blooming plants are over. It is especially useful for greenhouse decoration, where its stately spikes, clothed with a profusion of blue or white bells, afford an acceptable contrast to anything with which it is associated. In an ordinary living-room it will keep on blooming for six or eight weeks, all the attention required during the time being to supply it with water, and to pick off the flowers and seed vessels as the former decay, which otherwise interfere with those produced in succession.

To get the plants strong before the end of the summer, which is important, the seeds should be sown early in pans or boxes, in any ordinary light soil, whether it be loam or peat—I have found it matters little which. Press the surface smooth, and slightly cover the seeds with a little fine material. They will vegetate in a greenhouse or cold frame; but if a little heat can be given they will come up quicker. As soon as large enough to handle, the seedlings should be moved singly into small pots, kept near the glass, well supplied with water, and have sufficient air to keep them sturdy. If raised, as I have suggested, in a little warmth, the young plants should be prepared by cool quarters in a frame, with more air, for two or three weeks previous to the middle of May, when they should be turned out-of-doors in a bed of moderately rich soil, sufficiently light to admit of their being taken up for potting in the autumn without the mutilation of the roots unavoidable where the ground is heavy. Fifteen inches apart will give room enough for the plants to thrive, and all they will want during the summer is sufficient water when the weather is dry. This they should have, as, if not kept growing freely, they will not get strong enough to produce flower-spikes of full size. They should be taken up, with as little injury to the roots as possible, about the end of September, and placed in pots from 8 in. to 12 in. in diameter, according to the size of the plants, using a fair amount of drainage and good, moderately rich, and open soil, giving a good watering immediately, and putting them for a week or two in a frame, kept a little close until the roots have begun to act, or they will lose some of their leaves, which would necessarily reduce their strength. Near the glass in a cool greenhouse will be the best for them during the winter. Here they will keep on increasing in strength at the roots and making more leaves. This Campanula is a very free rooter; and through the spring, as the pots get well filled with young fibres, the plants should be regularly supplied with manure water, which ought to be continued weekly up to the time of flowering, by which means the spikes will often grow to a height of 9 ft. or 10 ft. They look much the best when each plant is only allowed to produce a single bloom-stem; to confine them to which, all that appear above one should be cut away as they show themselves. When the flowering is over, a plant or two may be allowed to mature seed; the rest should be cut down and planted out in the herbaceous ground, or wherever they are likely to be effective. This Campanula is a native of Carniola and hardy, consequently can be raised by sowing the seeds in the open ground; but if treated as above advised time is saved, and for pot culture the flower-stems forthcoming from plants raised by early sowing under glass are very much finer than I have ever seen from examples raised in the open air. It may also be increased from suckers; but these, again, rarely produce anything like the tall spikes that seedlings will.

I look upon it as anything but advisable to follow the course, now often recommended, of growing numbers of plants in greenhouses whose proper place is out-of-doors in the open ground; yet this Campanula—so easily managed, and so exceptionally fine when well grown—supplies a want amongst pot plants that very few greenhouse subjects do. I should recommend that both the white and the blue varieties be grown. In no position out-of-doors is it seen to better advantage than when planted amongst dwarf Roses, the latter pegged down. Strong plants from seed, that have not yet bloomed, introduced amongst the Roses in the spring, after the latter have been pruned and the shoots pegged into their places, make a display after the height of the Rose blooming is over such as I have never seen equalled by anything else. Here, again, its non-liability to aphides stands it in good stead, and saves that continual attention inseparable from the growth of any plants along with Roses that suffer from the aphides certain to be communicated by the Roses to them.

T. B.

How to Grow Epacrises.—These excellent plants for greenhouse decoration have a strong objection to artificial heat during certain stages of their growth, while at others it is highly beneficial and even necessary. Although the flowers do not fall off, like those of Camellias, forcing causes them to come small and puny and without their proper colour, and not only this, but it endangers the health of the plants; and yet, strange as it may appear, at certain times, as just remarked, a little warmth does good. This is after they are cut down and have begun to break again, and from thence onwards till they have made plenty of young wood, after which, the cooler and more airy they are kept the better and finer will the individual blooms be. All the different sorts of Epacrises delight in fibry peat, which should be chopped up moderately fine and have a portion of the earthy matter sifted out by using a small-meshed sieve, and as this will carry away any grit the peat may contain, the loss must be made good by adding a heavy sprinkling of sharp silver sand, and mixing the same well up before using. One of the most important things to attend to is to see that the pots are properly drained, as nothing is so inimical to the welfare of the plants as water-logged soil. A single crock over the hole, placed so as to fit and prevent the ingress of worms, is a good practice, and over this about 1 in. in depth of others broken about the size of a nut. If on these a little Sphagnum or common Moss be scattered, it will keep the interstices clear by preventing the finer portions of the peat from running amongst them, which it is otherwise sure to do, and thus impede not only the percolation of the water, but also interfere with a free circulation of air through the soil, by which alone roots can be kept in health. These being of a hair-like nature, the potting should be done firmly by ramming the peat well down with a blunt stick made for the purpose. The great mistake many make when shifting Epacrises and other hard-wooded plants is in filling the pots too full, by doing which sufficient room is not left to hold enough water to thoroughly moisten the ball through; and this is a frequent cause of plants dying or getting stunted in their growth when, to all appearance, the soil is quite wet enough, if judged by that on the top. Even with the smallest pots, the space left should not be much less than 1 in., and for others of larger size nearly double that is necessary; and with this much allowed, it is advisable, when watering has to be done, to go over the plants twice, so as to ensure a thorough soaking, for in this way alone can Epacrises be kept in perfect health.—S.

Propagating Gloxinias.—For ordinary purposes these can be raised yearly from seed, and where a good strain of this is at command the plants from such a source are all that need be desired; but where it happens that more than usually fine varieties exist either from seed or otherwise, it is well to increase them by cuttings made from leaves in the usual way. If the kind is scarce a single leaf will make three or four by notching the midrib at the underside, laying it flat on a pot or pan filled with sandy peat, ½ in. of the top all sand, and putting on the surface of the leaf, over each incision made on the underside, a pebble about the size of a pigeon's egg to keep the cut parts in contact with the sand. They need to be kept slightly, but not too moist; in this way they will form small bulbs in the course of the summer; but where the leaves of the kind or kinds to be increased are plentiful, larger bulbs will be obtained by putting each leaf in as a cutting, simply inserting the stalk end to the extent of 1½ in. in the soil.

Gardenias as Greenhouse Plants.—Gardenias may be made to thrive in an ordinary greenhouse by adopting the following treatment. After flowering, say in June, place them out in the open air in a somewhat sheltered situation. In September place them in the greenhouse, and in the following June and July they will yield abundance of blossoms, after which they should be treated as before. In this way a quantity of plants are treated in Messrs. Henderson's nursery at Pine-apple Place, and at the present time they are as healthy and floriferous as Gardenias could be.

Annuals for the Greenhouse.—Perhaps the most useful annual of all for pot work is Rhodanthe maculata alba and also Rhodanthe maculata atrosanguinea. These have very good points to recommend them. They are dwarf in habit, profuse flowerers, rich in colour, and chaste in form, and their flowers are "everlasting." They may be sown every month in the year with a certainty that the plants will bloom. They are very valuable decorative plants when grown in 4½-in. sized pots; but where they are grown for cutting from they should be grown in 6-in. sized pots. A light rich soil with good drainage will suit them well, and about six plants should be left in a 4½-in. sized pot, and about eight plants in a 6-in. sized pot. A large sowing of these should be made about

the middle of January, the produce of which will prove valuable during the early summer months. Next let us speak of the dwarf varieties of Sweet Scabious. These possess an excellent habit of growth, and are very floriferous. The colours of some of the varieties are very striking, and are quite distinct from anything I have ever seen in any other class of plants. These are most useful as autumn plants; and as they are somewhat slow growing, they will require to be sown earlier than many other annuals. The end of the present month is the best season in which to make a sowing. The best size pot in which to grow them is 8½ in., and these should be plunged outside during the summer, always taking care that the plants do not suffer from want of moisture at the root.—R.

FINE-LEAVED HOTHOUSE CLIMBERS.

Cissus discolor.—It is not too much to say that this is one of the most singularly beautiful of hothouse climbers. When grown in a warm temperature, which it ought to be, the leaves acquire that gorgeous lustre and colour which give the plant its splendid appearance; and it is only when it is allowed to scramble in festoons about the roof of a house, drooping its long tapering shoots here and there, that it is seen in its true character. To train it on a balloon-shaped trellis, as it often is for exhibition purposes, is about the worst way of growing it that could be conceived. The plant must have a high temperature and generous treatment, as it will grow 20 ft. or more during the summer months, and produce leaves splendid both in size and colour, and such as can be produced in no other way. It is seldom that this Cissus is grown in this way or grown well, and though the leaves are always beautiful, it is only when it is growing fast and draped with plenty of young shoots and leaves that a true idea of its beauty can be formed. It strikes freely from cuttings made from the points of the young growing shoots, and inserted in sand under a bell-glass, and plunged in a bottom-heat of about 90°. Young plants succeed best. We used to strike them annually in February for the purpose referred to, and always had good plants. As soon as the cuttings were struck they were potted off in 4-in. or 5-in. pots, and again plunged in bottom-heat in a hot pit, and when the roots reached the sides of the pots they were shifted, for the second and last time, into 10-in. pots; the compost should be loam and peat in equal quantities, about one quarter well-rotted cow manure, and plenty of sand if the loam be heavy. After this they were put in the same pit again till established, and then removed to the hothouse about the middle or end of April, when the temperature of the house had attained to about the summer figure. A plant was set to each iron column, up to the top of which they ran directly, and then they were led round the house on both sides of the path with string, which is handier than wire for festooning. It is too late now to put in cuttings, but young plants are cheap, and half-a-dozen are sufficient for a long house if treated as here directed. The only enemy almost the plant has is the mealy bug, but a little attention with the brush will keep it down if the plants be kept growing fast, as they then run away from it. Frequent applications of liquid manure will also be serviceable in promoting a quick and vigorous growth.

Cissus porphyrophylla, the subject of our illustration, is also a free-growing stove climber with variegated leaves, which may be usefully employed for clothing a pillar, rafter, or wall. It succeeds well in a pot in either peat or loam, but when space is limited it should have root-room proportionate to the space which it is intended to occupy, as if it has too much liberty at the roots, it will need cutting in more than is desirable; the soil when exhausted can easily be renewed in the spring before growth commences, as it sustains no injury from the roots being interfered with.—J. S.

ROSES.

White Fairy Roses.—We lately saw a house full of these in the Pine-apple Nurseries, Edgware Road, London. They were dwarf and compact, and laden with pure white, well-shaped blossoms. The flowers of Fairy Roses are, as a rule, of little value when fully expanded, but in the case of this kind they are an exception. Fairy Roses are not difficult to propagate, and they make admirable little window or greenhouse plants.

Green Fly on Roses.—A simple yet effectual method of clearing Roses of this pest is as follows:—Take a two-gallon water-pot full of water, put into it two wineglasses of paraffin, and then well mix with the syringe; afterwards syringe the Roses with the mixture. It will kill every fly, and will not injure the tenderest shoot or the Rose blooms. The air will very soon remove the smell of the paraffin. I have used it on my pot Roses in the house this year, and on my Gardenias at the rate of one wineglass of paraffin to two gallons of water.—THOMAS GREEN.

Roses on Banks.—In gardens where banks occur nothing could be more appropriate to plant them with than Roses on their own roots pegged down. The Roses would succeed

Bank of Roses.

remarkably well in such a position, provided the soil was good and mulching was not neglected in summer. Gladioli, pyramidal Campanulas, and other plants might be placed between the Roses with excellent results.

HOW TO COLLECT, DRY, AND MOUNT PLANTS.

IN forming a collection of dried plants there are four different processes to be performed. The first is the collection of the plants, the second is the preservation and drying of them, the third is the mounting, and the fourth the classification and arrangement. The manner of collecting plants can be very little varied, but there are many methods both of drying, preserving, mounting, and classifying the specimens.

First, a tin case, called a vasculum, will be found very useful for carrying the specimens immediately after being gathered. It will prevent them from withering for several hours, but yet there are some plants which can only be secured by being placed immediately in the drying paper; therefore, it is as well to take a few sheets of this paper placed between two pieces of wood or strong cardboard, in addition to the vasculum, when starting for a botanical ramble. A strong knife ought also to be taken to dig up the plants with their roots. In every case perfect and typical specimens should be gathered. When dried they are much more valuable if they embrace the entire plant, its root, stem, flower, stem-leaves, radical leaves, some of its flower-buds, and its fruit or seed. But if this rule is to be strictly adhered to, two specimens must be procured of each, for very few plants have flower-buds, flowers, and fruit or seed at the same time. On arriving home after a botanical ramble, the plants gathered should only in very few cases be placed immediately under pressure. They ought to have their stems immersed in water, and be left till the following day, when the flowers, which were closed when taken out of the vasculum, will have opened. Or, if there are only flower-buds, the plants should be left in the water until some of them expand.

Secondly, to dry the plants, the usual plan is to place them in natural positions between two sheets of bibulous paper under a slight pressure. Botanical paper specially prepared for drying plants is sold, but blotting paper serves quite as well, or even when that cannot be procured, newspaper will easily extract the moisture from them. When first the specimens are placed in the drying paper they are often very difficult to arrange in suitable positions, in consequence of their natural stiffness; but if this is the case, it is the best plan to arrange them as far as possible, and then leave them for a day under pressure. By this time they have become softened, so that they can easily be made to assume any form. If any of the leaves are doubled, they should be straightened with a penknife; and if there are so many petals in each flower that in drying three or four overlap each other, they should all be severed from the plant and dried separately; in mounting they can easily be replaced. But before placing them in the drying paper many specimens have to be botanically trimmed, and care has to be taken during this trimming process lest any notable features of the plant become altered. For example, suppose a portion of a Cow Parsnip (Heracleum spondylium) is to be pressed and dried: its stem is so thick, that it would require many pounds' weight of pressure, and a long time to become dry and flat. But to save all this extra pressure and increased space of drying time, the stem may be entirely cut away, except a thin strip, and the plant when mounted appears no less perfect than if its stem were whole. This plan ought to be adopted in the case of all thick and succulent or juicy-stemmed plants. Suppose, again, that we have to press such a plant as the Marsh Rosemary (Andromeda polifolia), or the Toad Flax (Linaria vulgaris), the stems of which are so covered with leaves, that it is almost an impossibility to make neat specimens of them as they naturally are: several of the leaves ought to be carefully cut away from the stem, and then those remaining can be easily pressed in their natural positions.

When the plants are arranged in the drying papers the pressure may be exerted either by placing them in books, or in a heap under a board which is weighted. A screw press is generally used by botanists. During the pressing and drying process the specimens ought to be well looked after. Twice or at least once a day they should each be placed in dry paper; or if neglected and left in the same part of the bibulous paper until they are perfectly dry, they require more time than they would do if occasionally removed to dry portions of the paper; and, besides, they are liable to lose their colour and become mouldy. Yet, with all precautions, it is almost impossible to preserve the flowers of delicate tints with those tints when dried. The colours most liable to change are light blue, pink, some whites, some yellows, and the green leaves of Orchids. Concerning the preservation of these colours, there was a short paragraph in one of the scientific journals a few weeks ago, in which it was recommended that with a small paint-brush the petals should be covered entirely with a strong solution of alum before being placed in the press.

Thirdly, before mounting all specimens should be perfectly dry, or if not, they are liable to become covered with mould. Separate sheets, of paper of a size not less than foolscap are the best to use; these may be too large for some plants, but two or three species may be fastened to the same sheet if they are small and all of the same class. There are two methods of fastening the dried plants to the sheets of paper: the one is, to use gum or glue and entirely fasten them with it; the other is, to use small slips of gummed paper, placing them across the stems and tips of the leaves. It is better not to keep strictly to either of these methods, but to use both, according to which

will serve the purpose best. It requires a little practice to manage the narrow slips of gummed paper easily, for nearly all of them ought to be less than the sixteenth part of an inch across, but after a time they are not much trouble. The only difficulties are seeing which is the gummed side of such narrow pieces and preventing them from sticking to the fingers intead of to the paper. First cut the gummed paper into these narrow pieces; then suppose a piece is required to place across the stem of a plant which is being mounted; cut off from one of the strips a short piece sufficient to easily fasten the stem to the paper; then hold this small piece between yourself and the light, so that the light can be reflected from it to the eye; the gummed side can then easily be seen. Wet this side, and with the point of the scissors pick it up; place it, gummed side downwards, over the stalk; wrap one of the fingers in a piece of linen—a pocket handkerchief will do—and then press upon it. It will soon dry, and thus fasten the portion of the stem over which it is placed. Afterwards proceed with the other pieces of gummed paper in the same way, placing them over the stem wherever they are required. Next the leaves and flowers must be fastened. Gum will answer this purpose in many cases better than gummed paper. In gumming the leaves either cover them entirely, or only touch the extremities, but always, whether the gum is used universally or partially, well press these parts, or the specimens, after being mounted for some time, will very likely shrivel and turn brown. This pressure may be exerted by the finger wrapped in linen, as in the case of the slips of gummed paper. When the plant is firmly fastened to the mounting paper, its Latin or scientific name ought to be affixed to it, in addition to its common English name; and if it is a native of Britain, it is better to add also the month when it was found in flower and the locality where it was growing.

Fourthly, passing on from the more practical portion of the subject, we come, to the more scientific portion. This is the classification of the specimens. There are two methods of arranging them according to their several characters. The one is known as the artificial system, and the other the natural system. The higher divisons of classes and orders in these two systems are founded on different principles, while the minor divisions, or the genera and species, are the same in both. In the artificial system one or two organs are chosen, and by means of these the classes and orders are formed; while in the natural system these divisions are made after taking into account the alliance of plants in all their important characters. Thus, although the artificial class and order of a plant may be known, its structure and properties are not thereby learned; but when the place of a plant in the natural system is known, a knowledge of all its structural relations and affinities is acquired. Therefore, the latter or natural system is much the best for the arrangement of a herbarium if it is to be instructive and useful.

In arranging the plants, it is sufficient to have them in their own orders, but then these should follow each other in natural succession; thus, the orders of the sub-class Thalamifloræ should come first in the herbarium, then those of the Calycifloræ, and so on. Place the species of the same order or family together, using a whole sheet of paper or thin cardboard as a kind of portfolio, and write the name on the back. A. S. W.

Labels for Plants.—I enclose a small slip of ground glass which I use for writing the names of my plants on instead of wood or metal labels. It is cut from glaziers' small scraps of glass, which can be bought for a few pence; in fact, I get them ready cut for much less than I can buy the painted wooden ones. I formerly used black-lead pencil, but found it washed off in course of time; but now I use an ordinary blue lead pencil, which will stand any amount of water, and even a moderate amount of rubbing, before it will come off. Several of my friends have adopted them since they saw how neat, clean, and distinct they looked when in the sides of the pots. I do not claim to be the first who may have used them, but as I have seen so many different dodges in the GARDENING ILLUSTRATED, I thought this might perhaps be acceptable.—C. D.

ANSWERS TO QUERIES.

2381. — **Clay's Fertiliser.** — From use during the past and present seasons, I have formed a very high opinion of the fertiliser as a powerful stimulant and as a permanent improver of the soil; the latter qualification I look upon as one of the special advantages the fertiliser possesses over artificial manures generally. I am using it largely, both for market garden crops and on experimental plots. I have tried it on Wheat and other cereals growing on shallow land rather out of heart, and which looked very yellow and starved until they received a dressing of Clay's manure; the dressing has produced a very marked improvement.

Fine-leaved Hothouse Plant (Cissus porphyrophylla).

For Peas, Onions, Strawberries, Celery, Lettuce, Cauliflowers, and all the Brassica tribe, I can unhesitatingly recommend it. I am also trying it on a considerable scale for Potatoes, Roses, root crops, Vegetable Marrows, and Cucumbers, and hope to render a good account of its effects on these further on. From 1 cwt. to 1½ cwt. per acre is the extreme that can safely be used for general garden or field crops. I have given the fertiliser to a few plants in pots, and find it produces freedom of bloom, combined with very healthy wood, but it must be used sparingly; about a teaspoonful at a time to a growing plant in a 6-in. pot will be the best guide I can offer. I like to alternate the dressings with clear soot water, allowing an interval of about ten days between each.—T. LAXTON, *Experimental Gardens, Girtford, Beds.*

2408.—**Making an Asparagus Bed.**—Next autumn, or any time when the land is vacant, wheel on a good dressing of manure, and if the soil is heavy add sand, burnt earth, charcoal dust, ashes, or anything of a similar nature to make it lighter. Trench it as deep as it will bear up to 3 ft., but do not bring any bad soil to the top. Mix the manure well with the soil as it is turned over. In the spring give it a good dressing of soot and salt, and fork it lightly in. In April procure some good one or two year old plants, and plant them the moment they come to hand in shallow trenches 3 ft. apart, and 18 in. from each other in the trench. Spread the roots out evenly, and cover the crowns 2 in. deep with some light, well pulverised soil. It is a good plan to prepare specially a few loads of compost for this purpose, as it gives the plants an early vigorous start. This is specially desirable in heavy, cold land. A light crop of some other dwarf-growing vegetable may be had from between the rows the first two years. Afterwards the plants will occupy most of the land. I may add the bed may be either 5 ft. or 500 ft. wide—the principle is the same for both.—E. H.

2413.—**Show Celery.**—To produce Celery for exhibition the right kind should be chosen and grown on rapidly without a check, and as such produce is not tasted by the judges, flavour is of no consequence—only size and finish need be regarded. Liquid manure should be frequently given which may be varied occasionally, sometimes giving guano in solution, at others drainings from the farmyard, or soot

mixed with water. Strings of soft roffea or matting may be tied loosely round as the plants grow to keep them together. All small offsets that spring from the sides of the main head should be removed before any covering is applied. Paper is the best material for covering when it is necessary for applying it. Collars are sold for the purpose by some of the seedsmen, which can be passed round the plant and fastened with hook and eye, but any ordinary paper will do simply passed round one or more folds thick, and secured with soft matting. It must not be bound round too tightly, as room must be left for the stalks to grow. The blanching material should be of a yielding nature, and at the same time effectually exclude the light. Soil finely pulverised is usually employed taken from each side of the rows in equal quantities, but where this is harsh and stubborn some material from another source should be sought; this is especially necessary where worms and slugs abound. Fine sifted ashes, burnt earth, and old tan are all suitable, and do not tarnish the skin of the stalks. The earthing should be finished about three or four weeks before the show.—E.

2406.—**Cauliflowers Going Blind.**—Blindness in the Brassica family may arise from various causes. The heart of the plant in its young state is no larger than a pin's point, and at that early period the least injury to it is fatal. Insects are often the cause of blindness; thick sowing may conduce to it; as may also drought or any cultural condition that produces a sudden check; and it may indirectly arise from constitutional defects.—E. H.

2394.—**Fruit for Exhibition.**—Thin the fruit now, the Plums to 3 in. or 4 in. apart, and the Apples and Pears to 6 in. Pinch or cut back all young wood, except leading shoots, to four leaves; and if dry hot weather sets in mulch or cover the soil over the roots with 3 in. or 4 in. of manure, and give a good watering occasionally. When the fruit begins to ripen turn on one side, or otherwise remove all overhanging foliage, and protect from birds.—E.

2401.—**Climbers for Bleak Aspect.**—The Banksian Rose, Wistaria sinensis, Ampelopsis Veitchi, Clematis Jackmani, Lonicera grata, Jasminum nudiflorum; one or two of the variegated Ivies might be added. I saw the front of a house the other day one side of which was covered with a small-leaved silver variety and the other with a golden form. All that was required to make the front of that house perfect was a few trailing shrubs of Clematis, or some other flowering creeper over and among the Ivy.—E. H.

2343.—**Figs Rotting off.**—Figs often drop in the way stated, especially if the roots are deeply buried and unrestricted. The blossoms of the Fig are inside the fruits, and their setting is not perfected till the fruits are half grown. During the period of inflorescence plenty of ventilation and a brisk temperature should be maintained. Don't water with spring water; pond or soft water is best. Chills of all kinds should be avoided. Figs have been cast off by watering with cold spring water. Lift the roots in the autumn and bring them near the surface, working in some fresh loam and old plaster.—H.

2411.—**Azaleas not Blooming.**—It is evident that the plants in question did not properly mature their growth, and consequently failed to perfect flower-buds. Keep them in a light, well ventilated house until the beginning of August, when they should be placed in a sunny situation in the open air, housing them about the middle or latter end of September. The more they are exposed to sun and air when out-of-doors the more freely will they bloom.—C. B.

2320.—**Climbers for Greenhouse.**—The attempt to grow Grapes in the situation mentioned could only result in disappointment, as the only way in which they can be ripened in an unheated structure is to fully expose them to the sun's rays during the summer months. The list of climbers suitable for a north unheated structure is of a rather restricted nature. Passiflora Newmanni, Stauntonia latifolia, and Lonicera flexuosa would probably do fairly well.—C.

2330.—**Sulphur from Greenhouse Flue.**—We know of nothing more likely to answer the purpose than fire-clay. Beat it well and thoroughly stop the joints, ramming the clay well home. Do not make a fire until the clay has become quite hard and dry, and if the weather is hot, cover the joints with mats, so that drying progresses very slowly. In all probability, even with the greatest care, some cracks will declare themselves, in which case a thick wash of clay should be made and well worked into them with a brush, repeating the operation as often as may be necessary. In this manner we think there will be little danger of sulphur fumes escaping. Ordinary brick clay may be used, but it is not so good as fire-clay. We should, however, mention that the pipes should not come within at least 8 ft. of the furnace, or the heat of the fire at that part will be sure to crack the joints, no matter what material may be used to stop them. Carry a good solid piece of brick-work about 8 ft. into the house, and then commence with the pipes. It is generally near the fireplace where the sulphur escapes, consequently the brickwork cannot be constructed in too solid a manner at that particular spot.—C.

2393.—**Insects in Cucumbers.**—Take 1 peck of fresh soot, tie it up in a coarse bag or cloth, and sink it in a tub that contains about 30 gallons of soft water. Stir it about well with a stick for two or three days, then water the roots of the plants and soil round about without wetting the leaves. If it appears too strong, dilute it. Use it as often as the plants require water, and I have no doubt an improvement will soon be perceptible.—E.

2388.—**Grapes Failing.**—The cause of the failure appears to be deficient ventilation, and this is the rock on which a good many inexperienced Grape growers founder. Unless the Grapes were forced the heat named would be too exciting for winter, and if they were forced a low temperature, say 45°, should be commenced with, gradually rising as the Vines progressed until the blossoms opened, and even then a night temperature of from 60° to 65° will be ample. The border seems right. The management of the interior must be altered. More air and less fire-heat seems to be requisite. No Vinery should be altogether closed after the sun strikes it in the morning.—E. H.

2386.—**Lily Failure.**—The cause of the white Lily failing in the manner it does in some places is a mystery to me. The plant is reckoned to be of very easy culture, and yet in certain districts it will not give satisfactory results. In this locality (Surrey) I have failed to see a well grown mass of this old Lily. It lives, the bulbs increase in size, and are when taken up to all appearance sound and vigorous. It starts freely into growth, forms its flowers, which, although they expand, are never good, but the lower leaves turn black and eventually disappear, thus rendering the plant very unsightly. In the very same soil (alluvial) and situation its congeners longiflorum and auratum thrive satisfactorily. Whether the decay of the foliage is to be attributed to a disease or imperfect root action I cannot say; my own impression is that it arises from the soil being too porous and open on the surface. When the bulbs are planted I would make the soil quite hard around them, never afterwards hoeing or in any way stirring it. Early in the spring I would apply a good mulch of some kind, or I would carpet the soil around with some low growing plant. The Lilies as a rule do best when the lower leaves and roots are protected against the sun's rays or drying winds. They appear most at home when springing up from the midst of other plants.—J. C.

2416.—**Winter Gardening.**—In the first place we would form a neat edging of the common English Ivy, a plentiful supply of plants of which may be obtained by taking off the terminal shoots wherever it may abound, inserting them in a shady place, and keeping them well watered until well rooted. In planting, insert the shoots quite 6 in. in the soil, pegging each one down as it commences to grow. When planting the Ivy, such flowering bulbs as Snowdrops, Crocuses, Fritillaries, and autumn Crocus may be dibbled in here and there. They will thrive in such company, and will look very pretty when in bloom. Plants which retain their verdure during the winter months consist of Periwinkles, both green and variegated, Christmas Roses, Saxifraga umbrosa, the London Pride, Alyssum saxatile, Arabis albida, and Aubrietia purpurea. Then there are Pansies and Violas, which remain green throughout the winter, and flower freely during the spring and summer in a shady situation. Lamium striatum is an excellent plant for winter bedding, being prettily variegated, and remaining fresh and bright even in the most inclement weather. If diversity of colour is desired, there are Cerastium tomentosum and Stachys lanata, two effective white-leaved plants.—C.

2395.—**Roses to Flower at Christmas.**—The flowering season of some of the Hybrid Perpetual and many of the Tea Roses may, by a judicious system of culture, be prolonged into the winter months. It is, however, imperative that suitable sorts be chosen; otherwise, but little success can be expected to attend the attempt to do so. The plants intended for such late-flowering should, if the pots are quite full of roots, be at once shifted into larger pots, and be placed in the open air in a sunny situation, plunging the pots up to their rims. If the plants do not need fresh potting, plunge them in the open air and top-dress with rotten manure or Clay's Fertiliser. Water freely when needful, syringe in the evening in hot weather, and pick off all buds as they appear until September, when they may be allowed to form. As soon as cold nights arrive place the plants in a well ventilated structure. Be sure to give plenty of air and apply no fire-heat. Plants thus treated may be expected to give bloom up to December, and in mild seasons even almost to Christmas. The following kinds are amongst the best for the purpose—Gloire de Dijon, Souvenir de la Malmaison, Madame Lambard, Homère, Catherine Mermet, Perle des Jardins, Niphetos, Souvenir d'un Ami, Souvenir de Paul Néron, Aimée Vibert, and Adam. Many other kinds will flower late in the autumn, but not so late as these.—J. C. B.

2397.—**Cobæa scandens.**—The better plan would be to plant out the Cobæa in a bed of prepared soil consisting of one-third leaf-mould and two-thirds turfy loam. The plant will grow much more freely if thus accommodated, and will not need so much attention as if grown in a pot. The sooner the plant is put out the better. If carefully attended to it should cover the desired space the first year. When it is seen that the roots have taken good hold of the soil and that short growth is progressing, pinch out the main shoots, stopping the laterals, which will then form when they have made several pairs of leaves. The main point is to well clothe the lower portion of the wall before allowing full freedom of development. If it is not convenient to plant out, the plants may be potted into 10-in. pots, draining them well, and mixing some silver sand with the compost. Be careful not to overdose them with water until the pots get full of roots, when they will require liberal treatment in this respect. In order to maintain the plants in a state of vigorous health they must every year receive a dressing of some concentrated manure, or be watered every week with clear soot or guano water.—B.

2415.—**Budding Roses.**—The Rose in question may be budded any time during the present month, providing the wood is in a proper condition for so doing. Only the wood made during the present summer is fit for operating on, and the buds should be inserted before the bark becomes hard. Roses seldom flower well when growing in partial shade; they should have a light, airy position; underneath Vines is certainly not a good place for them. If planted in the border, the Rose will rob the Vines of a portion of their nourishment.—J. C.

2410.—**Calceolarias from Cuttings.**—If you allude to the herbaceous kinds, do not attempt to propagate them from cuttings. Sow some seed now, placing it in a cold frame. Prick out the seedlings when large enough to handle, eventually transferring them to small pots, shifting them on as may be necessary. The bedding kinds are propagated in October.—B.

2409.—**Plants for Shelves.**—Zonal Geraniums, Heliotropes, Fuchsias, Lantanas, single Petunias, Lobelias, and Tropæolums should all do well in the situation mentioned. Perhaps ventilation at the top of the structure is deficient, which would account for the plants drawing. They ought not to do so at that distance from the glass.—C.

2402.—**Canadensis sanguinea.**—Have you not in mind Sanguinaria canadensis, the Canadian Bloodwort? Seed of this may be sown when ripe in a cold frame. We have no experience of it for forcing purposes.—J. C. B.

2385.—**Planting Honeysuckles.**—Take them up at the fall of the leaf about the latter end of October, taking care not to let the roots dry. Taking up strong growing plants in a wild state is very different from transplanting cultivated specimens, and is generally un-

satisfactory. Better procure a good stablished plant in a pot.—J. C.

2413.—**Show Celery.**—Bind stout brown paper round the heads half way up; don t earth up too early, and when nicely growing, tie the heads up with matting; earth up in dry weather. I grow very good Celery with the treatment I have named.—W. A.

2323.—**Insects in Cucumber Frame.**—I find keeping a few toads in my Cucumber frame a good way of keeping them free from insects. I have also smoked the plants a few nights steadily, and I have had nothing to trouble me in the pit or frame.—AMATEUR GARDENER.

2384.—**Celery for Exhibition.**—I have grown Celery for exhibition, and, by binding stout brown paper about half way up the heads, I find them well blanched and quite free from worms.—AMATEUR GARDENER.

Although the following questions are answered by the Editor, he will be obliged to any of our readers who may think well to answer them again.

2462.—**Ageratums for Next Year.**—*Brown Eyes.*—Take cuttings now, and when struck pot them singly and place them in a sunny situation out-of-doors, plunging the pots in ashes. Shift into larger pots as necessary, and stop the shoots several times to make the plants grow bushy. In September remove them to the greenhouse, and they will flower in winter and spring; after which if they are cut back they will form good plants for the flower garden in June.

2463.—**Cutting Down Tall Geraniums.**—*Brown Eyes.*—We presume you mean zonal Pelargoniums. Cut them down now to within 6 in. of the pot. When they commence to grow again take off as much of the top soil as you can, and top-dress with good sandy loam and make firm. Keep the flower-buds picked off, and pinch out the points of the shoots when they are getting too long. Plunge the pots in ashes in a sunny situation; take indoors at the end of September, and they will bloom in autumn.

2464.—**Training a Plumbago.**—*Brown Eyes.*—All climbers should be kept on the outside of the trellis, as they can then be readily taken down to be cleaned should that be necessary.

2465.—**Frogs in Greenhouse.**—*Brown Eyes.*—Frogs are of little use in a greenhouse for the purpose of killing insects; a toad would be useful. If the floors and stages of the house are dry—which they should not be at this time of the year—a little water should occasionally be poured over the toad through a fine-rosed watering pot. This bath it will enjoy; you can feed it on worms if there are not enough insects in the house for it to live upon, but overfeeding will render it useless.

2466.—**Lettuces Damping off.**—*G. H. M.*—Unless the plants are very close together we cannot understand them damping off. This has been one of the best seasons for Lettuces we have ever known.

2467.—**Lead Water and Plants.**—I have a wooden cistern lined with sheet lead to catch the rain from my greenhouse roof. Will the lead in any way contaminate the water so as to render it unfit for watering the plants?—DOUBTFUL. [No.]

2468.—**Barren Strawberries.**—When examining the Strawberry plants in the spring, how can I tell which are barren ones?—G. H. [Those that do not show flower are the barren ones, of course.]

2469.—**Fly on Currant Trees.**—*S. B.*—Give the trees a good syringing with the following mixture: 4 oz. of Quassia chips boiled in 1 gallon of water for a quarter of an hour; strain through a piece of canvas and add 4 oz. of soft soap. Use when cold. Half-an-hour after syringe with clean soft water.

2470.—**Worms in Flower-pots.**—How can I destroy worms in flower-pots without injuring the plants? I have tried lime-water without success?—G. H. E. [Put a 6-in. flower-pot full of slaked lime into a bucket of water and well mix. Then put the pots which have worms in them gently into the bucket till the water is up to their rims, but do not allow it to run over. If you hold them in this position for a few minutes the worms will come to the top.]

3471.—**Fly on Cucumbers.**—*A. W.*—Fumigate them a few nights in succession, but take care the smoke is not too hot, and do not give it too strong at a time.

2472.—**Spring Flowers for Sale.**—*M. A.*—You should have no difficulty in disposing of early spring flowers in Covent Garden, but unless you can supply them in large quantities, the carriage, &c., would take all the profit.

2473.—**Manure Water for Plants.**—*Brown Eyes.*—Such plants as are pot-bound and flowering freely will be benefited by regular supplies of manure water. It is better to apply it weak and often than to give strong doses at longer intervals.

2474.—**Culture of Rhubarb.**—*R. M.*—Rhubarb of whatever variety succeeds best in deep well-manured land. The plants should have plenty of room to develop themselves. An open situation is the best, but good results may be obtained by planting between fruit trees. Planting may be done at any time after the leaves have died down. Myatt's Victoria is one of the best kinds for general culture.

2475.—**Blue Sweet Pea.**—*C. B.*—Blue is not an uncommon colour in the Sweet Pea, but a real blue like that in the flowers of Lobelias or Salvia patens would be worth careful attention.

2476.—**Thinning Strawberry Leaves.**—*Amateur.*—It would not materially affect the plants to remove a few of the leaves in order to allow the sun to shine on the fruit, but we should think the fruit could be exposed without pulling off the leaves.

2477.—**Insects and Mushrooms.**—*J. B.*—We suppose the insects to be wood-lice. Keep a toad or two in the house; also try a small ridge of soot all round the bed.

2478.—**Planting Roses.**—*A. W. S.*—Dwarf Roses on their own roots might be planted now if obtained in pots, but autumn would be the best time. As regards sorts, if you apply to a good nurseryman he will select for you those which are likely to succeed best in your soil and situation.

2479.—**Removing Asparagus Roots.**—*Shirley.*—Old Asparagus roots seldom succeed well after removal. If you determine to try, do it in early spring; but young plants will pay best, and one-year-old plants might be planted now with success; older plants than these are best removed in spring.

2480.—**Sowing Hardy Perennials.**—*C. J. W.*—Seeds of some of these to yield plants to flower next year should be sown now. Much, however, depends upon what kinds you wish to sow.

2481.—**Plants in Rooms.**—*F. W. P.*—Plants placed on shelves round a room which has only a window in front are sure not to succeed, and those which grow will become drawn. You must either put a glass roof on the room, or be content to have a few plants in the window only.

2482.—**Raspberries Unfruitful.**—*Somerset.*—If your Raspberries are unfuitful every year, you must have got a barren sort, which should be rooted out and replaced by a better kind.

2483.—**Orchids in the Sun.**—Our house is so situate that the sun streams in on our Orchids at about 3 o'clock. Will it hurt them?—KRITES. [The sun will not hurt the plants if it does not shine strongly on them until 3 o'clock in the afternoon and a moist temperature is kept in the house.]

2484.—**Blight on Apple Trees.**—*M. S.*—Syringe the trees well with water in which has been mixed paraffin at the rate of two wine-glasses full to a bucket of water. Mix by drawing the syringe full several times, and ejecting it into the bucket. Repeat this several times during the operation. In a week or so repeat the operation.

2485.—**Fuchsias not Flowering.**—I have several Fuchsias in my house, and to all appearance they are in a very healthy state, and some of them have a good quantity of buds on, but as soon as the buds get to a good size and about to open they fall off. They get the morning sun, plenty of air, well drained, plenty of rain water kept in tubs on purpose, and every three or four days I water them with liquid manure sufficiently diluted with water.—HOROLOGICAL. [Give manure water once a week and try the effect.]

2486.—**Putting in Cuttings of Violas and Pansies.**—*C. J. W.*—From now till the end of August is the best time to put in cuttings of these. Plant them in a bed of sandy soil in a shady situation, making the soil firm. Plant out in September or in spring.

2487.—**Sowing Pansy and Viola Seeds.**—*C. J. W.*—If sown in August and planted out in spring they will flower next year and yield cuttings in the autumn.

2488.—**Damage done to Gardens by Cows.**—*J. R.*—Your neighbour cannot be held liable for damage done to your garden by his cows if the fence they get through is in a bad state and belongs to you. If the fence belongs to him he is liable. If you leave your garden gate open you can hardly expect to keep cows out, even if they were only being driven along the road.

2489.—**Vegetable Marrows Shrivelling.**—*Busy Bee.*—Vegetable Marrows in a frame in the full sun would not be likely to succeed well. Remove the light from the frame, and let the plants have plenty of air. Guano water applied three times a week is too much for plants in a young state. When large and bearing a heavy crop of fruit it would be beneficial. Water with clear water only at present, and this only when the plants need it; then give a thorough soaking.

2490.—**Earthing-up Cabbages.**—*Busy Bee.*—Many good cultivators never earth up their Cabbages, whilst others believe it necessary. Leave one row unearthed and you will be able to judge from experience which way is the best.

2491.—**Cutting Tendrils off Cucumbers.**—*Tender and True.*—The tendrils are just as well pinched off, as they are of no value to a plant that is kept regularly trained.

2492.—**Grubs in Carrots.**—*George Lee.*—The crop is too far advanced now, we fear, to allow of any effectual remedy being applied. You might try soot water. Put half-a-peck of soot in a bag into, say, 10 gallons or so of water. A brick may be tied to the soot bag to sink it. Well stir it about for a day or two, and water the bed with the liquor; 1 lb. of salt added may do some good. Use a watering-pot without a rose, so as not to water the foliage.

2493.—**Training Cucumbers.**—*Telegraph.*—Six feet is too great a distance between the Cucumber bed and the greenhouse roof, but if you train the leading shoot straight up and tie the side shoots to a wire trellis or some stakes, you may get fruit much earlier than by cropping that part of plant only that reaches the trellis under the roof. When fruit shows leave one leaf beyond it, pinching out the growing point.

2494.—**Paraffin and Plants.**—*Novice.*—The water from a cask which has been used for paraffin will produce no ill effects on plants.

2495.—**Increasing Raspberries.**—*X.*—You can increase them by digging up in autumn the young canes which have formed this season.

2496.—**Planting Uncultivated Land.**—*A Working Man.*—If the ground has not been dug up for years and is in a bad state, we would advise you to work it well ready for planting in spring. A deep trenching, and working, and plenty of manure will be necessary, but we cannot tell you further without knowing what kind of soil it is—whether heavy and clayey, or light and sandy.

Red Spider on Apple Trees.—*C. E. S.*—Syringe the trees well every morning and evening for a time and try the effect.

The Shakespeare Gooseberry.—*S. de Jersey.*—The Shakespeare Gooseberry is a similar kind to the one you send, but it has a reddish skin. We will try to ascertain the correct name.

Pansies.—*H. Williams.*—Apply to Messrs. Downie & Laird, Edinburgh; Mr. Laing, Stanstead Nurseries, Forest Hill; Messrs. Dicksons & Co., Waterloo Place, Edinburgh; Mr. Hooper, nurseryman, Bath; or Mr. Dean, Bedfont, Hounslow, Middlesex.

Silkworms.—*G. H. M.*—If you procure a copy of GARDENING for November 15 of last year you will find an illustrated article on the subject.

Blight on Apple Trees.—*T. G.*—Well syringe the tree with water in which has been well mixed paraffin at the rate of two wine-glasses to the gallon.

Green Fly on Celery.—See answer to "S. B."—Fly on Currant trees,

Orchard.—Shaw's "London Market Gardens," price 2s. 9d., post free from our office.

Names of Plants.—*H. R. T.*—1, Asplenium alatum; 2, Asplenium Filix-Fœmina; 3, Onychium japonicum.——*H. C.*—1, Delphinium cashmerianum; 2, Campanula rotundifolia; 3, Campanula Rhombodia.——*G. G. K.*—1, Geranium sanguineum; 2, cannot name without flowers; 3, Veronica longifolia.——*Rev. L. A. B.*—Genista tinctoria flore-pleno.——*Mrs. S. Hartland.*—Geranium macrorhizum.——*Samuel Knight.*—Apparently the Winter Cherry (Physalis Alkekengi).——*Selby.*—1, the Day Lily (Hemerocallis flava); 2, Weigela rosea; 3, Solanum jasminoides.——*J. L.*—1, Origanum vulgare aureum; 2, Euonymus radicans variegatus; 3, Euonymus radicans aureus variegatus.——*T. G. L.*—The old York and Lancaster Roses; very beautiful.——*G. H. M.*—A variety of the Monkey Flower (Mimulus).——*W. G.*—Begonia nitida coccinea.——*R. C. S.*—Diplacus glutinosus.——*Pink.*—It is a variety of the Garden Pink, and a very good one we think. We cannot name it.

QUERIES.

2497.—**Fungus on Lawns.**—Will any one tell me the best means of destroying the fungus on my lawn? I have pulled up the Toadstools carefully by the roots, but they return, and the "fairy-rings" remain and spoil the Grass. I live near the sea, and the soil is sandy.—C. L.

2498.—**Buddlea globosa.**—How is this propagated?—ROBIN.

2499.—**Propagating Syringas.**—When is the best time to propagate these shrubs? and which is the best way?—ROBIN.

2500.—**Flowers for Button-hole.**—Being very partial to button-holes, and having a small greenhouse what flowers can be easily grown suitable for making them, leaving Roses out of the uestion?—F. W. W.

2501.—**Roses not Blooming.**—I have a Maréchal Niel and Cheshunt Hybrid Rose two years old, planted in a conservatory, S.E., heated in the winter, but the Roses, though growing, leaves healthy, have not flowered. I have given liquid manure. What is the cause? The leaves show mildew, yet the house is kept open.—C. C.O.

2502.—**Drying Herbs.**—I shall be glad to know a practical method of drying and pressing herbs like those to be purchased in Covent Garden Market.—NUMBER SIX.

2503.—**Seedling Pomegranates.**—How should I treat these after they have been a month above the ground?—B. C.

2504.—**Cottage Flower Shows.**—Will "Yorkshireman in Cumberland" kindly give me further information on this subject, as he promised in GARDENING, May 15?—A. F.

2505.—**Beta Cicla brasiliensis.**—Can any one tell me the best way to cultivate this plant for winter decoration?—T.

2506.—**Drying Aquatic Plants.**—How can I dry aquatic plants? I have failed completely in trying to dry Hottonia palustris, at least the leaves of it. As soon as I take it out of water the leaves cling and I cannot separate them.—MISS S.

2507.—**Plants for a Fern Case.**—I have a Fern case the Ferns in which do not get on at all. What other plants will do in it in pots?—TRIANGLE.

2508.—**To Make Putty.**—Will any reader inform me the proper proportions of oil and whitening to make putty for a garden frame. I have used colza oil with whitening, but after a few weeks it all crumbled away. Is this the proper oil? and should any other ingredient be used?—RECTOR.

2509.—**Hoya carnosa.**—Will any reader kindly give me treatment for above? I have just purchased one which seems to be potbound. Shall I repot it now?—OMICRON.

2510.—**Arbutus.**—Will any reader inform me what soil suits this best. I planted one two years ago in my garden, but this year it has nearly died. Can I cut all the dead part away?—OMICRON.

2511.—**Aspects for Hardy Flowers.**—I am about taking a house with the usual stereotyped suburban back garden. It is the width of the house, with a low wall all round, and under this wall runs a bed about 3 ft. wide, then a walk; the centre of the garden is a Grass plot, in which beds can be cut. These three walls and the house give every variety of aspect, the centre being most exposed to air and sun. I only intend growing hardy flowers, but want to do the best I can with them. Will some skilled gardener say what aspect will best suit each of the following flowers: whether south, east, west, or north, or centre:—Pinks, Carnations, Roses, Fuchsias, Auriculas, Phloxes, Primroses, Polyanthus, Hepaticas, Cyclamen, Christmas Roses, Pansies, Sweet Williams, Delphiniums?—AILENROC.

2512.—**Anthericum variegatum.**—Will some one tell me how to grow this plant?—S. S. T.

2513.—**Renovating a Garden.**—I have a suburban garden that has been used as a poultry run; a large quantity of coal-ashes have been strewed over it and dug into it; it seems to be about half soil and half ashes; it will easily crumble, but is not rich or mellow. Some plants and flowers seem sickly in it. What would be the best thing to add to it or do to it during the autumn or winter months, so as to bring it into good condition for next spring?—T. J. S.

2514.—**Ants and Strawberries.**—We have in our garden a fine bed of Strawberries which never fail to supply an abundance of fruit. This year I see the ants are making sad havoc among them, actually scooping out fine ripe fruit. Will any one kindly help me to get rid of them?—ANT.

2515.—**Management of a Room Fernery.**—I should be glad of any information as to the best way of managing a small glass Fernery in my drawing-room? Should it be kept perfectly air-tight and well watered, or not? Mine does not flourish the Ferns either have the green fly, or else become mouldy.—ANNIE.

2516.—**Evergreen for Covering Fence.**—Will any one tell me of a quick growing evergreen climber to hide an ugly fence, 9 ft. high, aspect N.W.? At present it is partly covered with Ivy, which, however, does not do well, as it requires nailing and does not grow thickly, as on a wall, always looking untidy. I must have evergreens, as I have no difficulty in hiding it in summer; but in winter, when there is nothing else to catch the eye, it is very obtrusive.—APIS.

2517.—**Wireworms in Gardens.**—Our garden is completely overrun with wireworms. They have this year destroyed our Runner Beans, Potatoes, Cabbages, and Peas. Could some reader propose a remedy?—TYKE.

2518.—**Plants for Exposed Beds.**—Can any one suggest a plan for filling beds in an exposed situation where flowers do not do well? Would shrubs look well? The soil is limestone, so that Rhododendrons will not grow. Would Cotoneasters make a good bed?—EINNA.

2519.—**Pruning Currant and Gooseberry Trees.**—My Currant and Gooseberry bushes have made much new wood, some branches 18 in. long. Should I cut it back?—W. PROCKTER.

2520.—**Christmas Roses in Pots.**—I should like to know the treatment the Christmas Rose in a large pot requires? I want it as a greenhouse plant.—W. PROCKTER.

2521.—**Nertera depressa.**—Can any one give me proper directions for the culture of Nertera depressa? I have tried it in many different ways, but find it turns black, and now I have only a few berries on my plant, and they are not looking well.—S. DE JERSEY.

2522.—**Book on Painting Flowers in Oil.**—Can any one tell me of an instructive book on this subject?—MONTE CRISTO.

2523.—**Rose Tree Dying.**—Will any one tell me why a climbing Rose tree should suddenly begin to die, one branch after another? The only thing I observe about the plant is a scar like a burn near the bottom of the stem.—HAREWOOD.

2524.—**Geraniums not Blooming.**—Why do my Geraniums not flower freely? They are planted out in beds, some in shade and some in sunshine; some I keep in the greenhouse, and others stand out in their pots; but none ever produce more than one or two blossoms at a time. What can I do to make them bloom?—A. C. D. P.

2525.—**Fern Fronds Withering.**—I have a Polypodium phigopteris in pot kept in room, no gas, not exposed to sun, and regularly and well watered. It throws up new fronds abundantly, but they wither before arriving at maturity. What can be the cause?—H. S. G.

2526.—**Abobra viridiflora,** Canarina campanulata, and Medeola asparagoides.—How can I grow these? The plants were procured from Holland three years ago; they grow for a while, then dwindle away, and never flower.—W.

2527.—**Cape Gooseberries.**—Can any one give me any information on growing Cape Gooseberries, as I have some plants about 6 in. high in 3-in. pots standing on a shelf in a Cucumber house?—A. B. C.

2528.—**Insects and Mignonette.**—Mignonette being a great favourite of mine, I sowed a quantity of it this year, and with an amount of pleasure watched its rapid progress. Business called me from home for a few days; when I returned the greater portion of my Mignonette was withered to the ground. On pulling up some of the plants I discovered a little lump on each root, which lump I carefully examined. Inside was located a tiny insect of a whitish-brown colour, resembling a small spider. Can any one tell me how to destroy the insect, and preserve the Mignonette which remains?—DICK.

2529.—**Grapes not Progressing.**—On one Vine there are about half-a-dozen bunches of Grapes, which during the last three weeks have made no perceptible progress whatever. They are hardly larger than a pin's head now, and they were just as large three weeks ago. Can any one tell me the reason and give me some instruction? There are three Vines, and the bunches are forming beautifully on the middle Vine. Ought fire to be kept when we have no sun heat?—RHOS.

2530.—**Climbers for Cottages.**—What would be the best sort of climber for the front wall of a cottage facing the south? I think a climbing Rose or Clematis would look well, but would like the opinion of some one who has had experience in the cultivation of climbing plants.—R. M.

2531.—**Propagating Sweet Briers.**—I have a Sweet Brier tree, and am wishful to have some young ones. Will any one give necessary instructions?—W. J.

2532.—**Blight on Ferns.**—Will any one tell me the best way to destroy blight in a little window conservatory? The Ferns grow well and look healthy, but the young fronds get the usual small green blight, and also a minute insect like a thread of white cotton, which I never remember seeing before, and at first could not believe was an insect at all. Will it injure the Ferns to water with any preparation?—A. B. C.

2533.—**Keeping Roses Fresh.**—Is there any way of keeping Roses in a cut state fresh for any length of time?—C. E. S.

THE HOUSEHOLD.

Our readers will oblige us by contributing for this department useful receipts which they have tried and found good. Our desire is to make known all good and simple ways for cooking, or otherwise serving or utilising the various products of the garden and orchard.

GOOD VEGETABLE SOUP.

THERE is an important distinction, recognised chiefly on the Continent, and related to the demands of religious observance, between soups which have meat for their basis *(potage gras)* and those which have fish or exclusively vegetable bases *(potage maigre)*; into the latter class also eggs are admitted. They are referred to separately here in order to draw attention to a fact not generally recognised in this country, that excellent soups may be made without employing meat. Vegetable soups, clear and thick, are extremely palatable, the former being agreeable and wholesome, especially in the warm season when fresh vegetable growth is abundant and full of juice and fragrance; and the latter or thick soup may be very nutritious also, since they contain a considerable quantity of Barley, Peas, Beans, Haricots, Indian Corn, Rice, &c. I append the following as an example of a good *consommé* made from vegetables only, and therefore *maigre;* if well done it is very fragrant and agreeable in warm weather.

Consomme of Fresh Vegetable Roots.—Cut in slices 2¼ lb. of Carrots and the same weight of Onions; put them in a stewpan with some Parsley, Thyme, Shallot, and Celery, and also 1 lb. 2 oz. of butter; fry gently to a red colour, add 8¾ pints of water, let it boil, and skim it. Next put into it 1¾ pints of Peas and a couple of Lettuces; then add 1¼ oz. of salt, ⅓ oz. of whole Pepper, one pinch of Nutmeg, three Cloves, 1¾ pint of dried Peas, 1¾ pint of white Haricots; let it simmer for three hours at the side of the fire, skim off the grease, and strain through a cloth; then put aside for use. This *consommé* may form the basis of spring soup, *jullienne, brunoise, aux œufs pochés, crécy,* &c., fresh vegetables being added in each case as required in the ordinary way.—*Food and Feeding.*

POULTRY.

Fowls Making Strange Noises.—I have a black Spanish fowl which about every five minutes makes a strange cawing noise. Will any one tell me if there is any cure for it? she eats and lays well, and has the run of a large meadow.—CONSTANT READER.

Brahma Fowls.—Will any one be kind enough to tell me the real colour of the Brahma fowl?—J. T. L.

Fowls Going Blind.—Can any one tell me how to remedy (if there be any) the above? My fowls are almost pure Spanish, but there is a little of the Dorking in them. I am told it is not an uncommon thing for them to go blind whilst moulting, although I never saw such a thing occur before, which to me is rather singular, having always kept poultry.—C. S.

Eggs Hatched in Dog Days.—In this part (Wilts) it is said that chickens from eggs hatched in dog days never thrive, always having something the matter with them. Can any reader tell me if this is true, or only a superstition?—J. L.

Poultry Keeping in Rooms.—I have two rooms over a workshop about 18 ft. by 9 ft., facing east, with small windows north and south, partly boarded, the other part brick. I should like to know if I could keep fowls in them? if so, how many in each room? If it would answer, I should like to take the roof off the top room, so that it was quite open, with the exception of a small place for them to roost in. What cheap covering could I use for the floor, so that the wet could not get through?—PISCATOR.

Hens Hatching Turkey Eggs.—In answer to your correspondent in respect to hens hatching turkey eggs, I beg to say I have hatched them under Brahma and Cochin hens. I pick out the thickly-feathered birds and about two years old; in fact, the hens (Brahmas and Cochins) bring turkeys up better than the turkeys.—ROBT. BIGGENDEN.

Pullets Laying Early.—I have always thought that young pullets commence to lay when about eight months old. I had a setting of Crève cœurs hatched on March 7, and two of the pullets laid their first egg on June 19, being only a little more than three months old. Is this not very extraordinary? or is it a characteristic of this breed?

Nests for Sitting Hens.—I have got thirty-five chicks hatched by three hens since March 16. The nests were made in old tea-chests placed on the ground with some soil made hollow in the middle and a little hay placed on it. All did well, and are strong and growing rapidly.—MABOR.

Globe Mowing Machine.—A new mowing machine under this name is now being brought out by Messrs. Ransome and Co., Ipswich. Its speciality is that it will cut long rough Grass as well as closely shave the finest turf. We had an opportunity of testing it lately, and it performs perfectly all that is claimed for it. It cuts evenly and well without ribbing or tearing the Grass. Where lawns can only be mown occasionally this machine will be found of great value, whilst it is equal to, if not better than Ransome's well-known Automaton for use on a well-kept lawn. The knives are made of steel and wrought iron of great thickness, and are not so liable to breakage as in the case of steel knives screwed on to a cast-iron barrel. A 14-in. machine can be worked by a man, whilst a boy could work a 10-in. machine easily. Every part of the machine is adjustable, and it can be fitted with one handle like the American machines, or with two handles like the Automaton. It can be used with or without a collecting box, and altogether it appears to be a machine likely to be used largely when it becomes known. We may add that the wheel guards are so constructed that the Grass cannot clog the wheels, and they can be removed without interfering with any other part of the machine.

Catalogues of Pelargoniums.—I am endeavouring as far as possible to make a complete list of all the zonal Pelargoniums now in cultivation. Allow me through the medium of your columns to ask all nurserymen who feel disposed to assist me to send me their catalogues as soon as possible.—C. C. EWBANK, *Langford Vicarage, Biggleswade.*

A French Way of Killing Slugs.—The Paris *Figaro* gives the following advice to gardeners:—Do not waste your Orange peel, but make an incision round it midway and remove carefully in two halves; take the two cups and place them, hollow downwards, one on the Grass and the other among the plants or vegetables; at the end of a few days you may be rid of all slugs, black or green. Every morning you will find they have taken refuge under the two cups of Orange peel, and can be easily destroyed.

COVENT GARDEN MARKET.

WHOLESALE PRICES.

Cut Flowers.—*Per dozen bunches.*—Anemone, 2s to 6s; Azalea, 4s to 9s; Cineraria, 6s to 12s; Ferns (various), 3s to 9s; Heliotrope, 6s; Lily of the Valley, 4s to 12s; Lilac, 2s to 8s; Mignonette, 4s to 9s; Narcissus, 6s to 12s; Pelargoniums (zonal), 3s to 6s; Pelargoniums (large flower), 6s to 12s; (double), 6s to 12s; (Rose-scented leaf), 6s; Spiræas, 6s to 12s; Tropæolums, 1s to 3s; Tulips, 4s to 9s: Violets (blue), 1s to 2s.—*Per dozen flowers.*—Abutilon, 4d to 6d; Arum Lilies, 3s; Tree Carnations, 1s 6d to 3s; Eucharis, 4s to 6s; Gardenias, 2s to 8s; Roses, 1s 6d to 6s.—*Per dozen sprays or trusses.*—Bouvardias, 1s 6d to 3s; Fuchsias, to 4s; Primulas (double), 9d to 1s; Stephanotis, 2s to 4s.

Plants in Pots.—*Per doz.*—Arum Lilies, 9s to 12s; Adiantum cuneatum (ordinary), 6s to 18s; Begonias (flowering), 6s to 12s; Begonias (fine-foliaged), 6s to 12s; Bouvardias, 12s to 18s; Cineraria, 4s to 12s; Daphne indica, 4s to 6s; Dracæna (green-leaved kinds), 12s to 30s; Euonymus, 4s to 12s; Euonymus (variegated), 6s to 18s; Ferns (greenhouse and stove, various), 6s to 18s; Ficus elastica, 18s to 60s; Fuchsias, 6s to 12s; Gardenias, 24s to 36s; Lily of the Valley, 12s to 24s; Mignonette, 6s to 9s; Nasturtium, 3s to 6s; Palms (small), 18s to 60s; Pelargoniums (fancy), 9s to 24s; Pelargoniums (scarlet), 4s to 9s; Pelargoniums (double), 6s to 12s; Roses (hybrid perpetual), 12s to 24s; Spiræa japonica, 6s to 18s; Selaginellas, 3s to 4s; Virginian Creepers, 6s.—*Per pair.*—Maiden-hair Ferns (large), 4s to 7s; Palms (large), 15s to 42s; Amaryllis, 1s 6d to 3s each.

Fruit.—Apples (culinary), per bushel and barrel, 9s to 30s; Cobs and Filberts, per 100 lb. 120s; Grapes (English hothouse), per lb, 2s to 6s; Lemons, per box, 30s to 35s; Oranges (various kinds), per 100, 8s to 16s; Pomeloes, per dozen, 3s to 6s; Pine-apples (St. Michaels), each, 5s to 15s; Pine-apples (English hothouse), per lb, 2s to 3s; Strawberries per lb, 9d to 2s; Gooseberries per qt, 3d to 6d.

Vegetables.—*Per* 100.—Asparagus, 3s to 5s; French Beans, 9d to 1s. *Per dozen bunches.*—Carrots (outdoor), 4s to 5s; Watercress, 6d to 8d; Leeks, 1s 6d to 3s; Mint, 4s to 6s; Parsley, 4s; Turnips, 1s to 1s 9d; Radishes, 9d to 1s; Herbs, 2d to 6d. *Per doz. punnets.*—Cress, Mustard, or small salad, 2s. *Per dozen.*—Cucumbers, 4s to 7s; Endive, 2s to 3s; Lettuce, 6d to 1s. *Per bundle.*—Horseradish, 3s to 6s. *Per lb.*—Shallots and Garlic, 6d; New Potatoes, 1d to 3d. Chervil, per punnet, 3d; Corn Salad, per half-sieve, 2s; Mushrooms, per pottle, 1s 3d to 1s 9d; Potatoes (general store, round kinds), per ton, 100s to 200s; Kidney, per ton, 120s to 180s; Parsnips, per tally, 5s to 7s; Rhubarb (per dozen bundles), 2s to 3s; Spinach, per half-bushel, 2s 6d; Tarragon, per bunch, 6d.

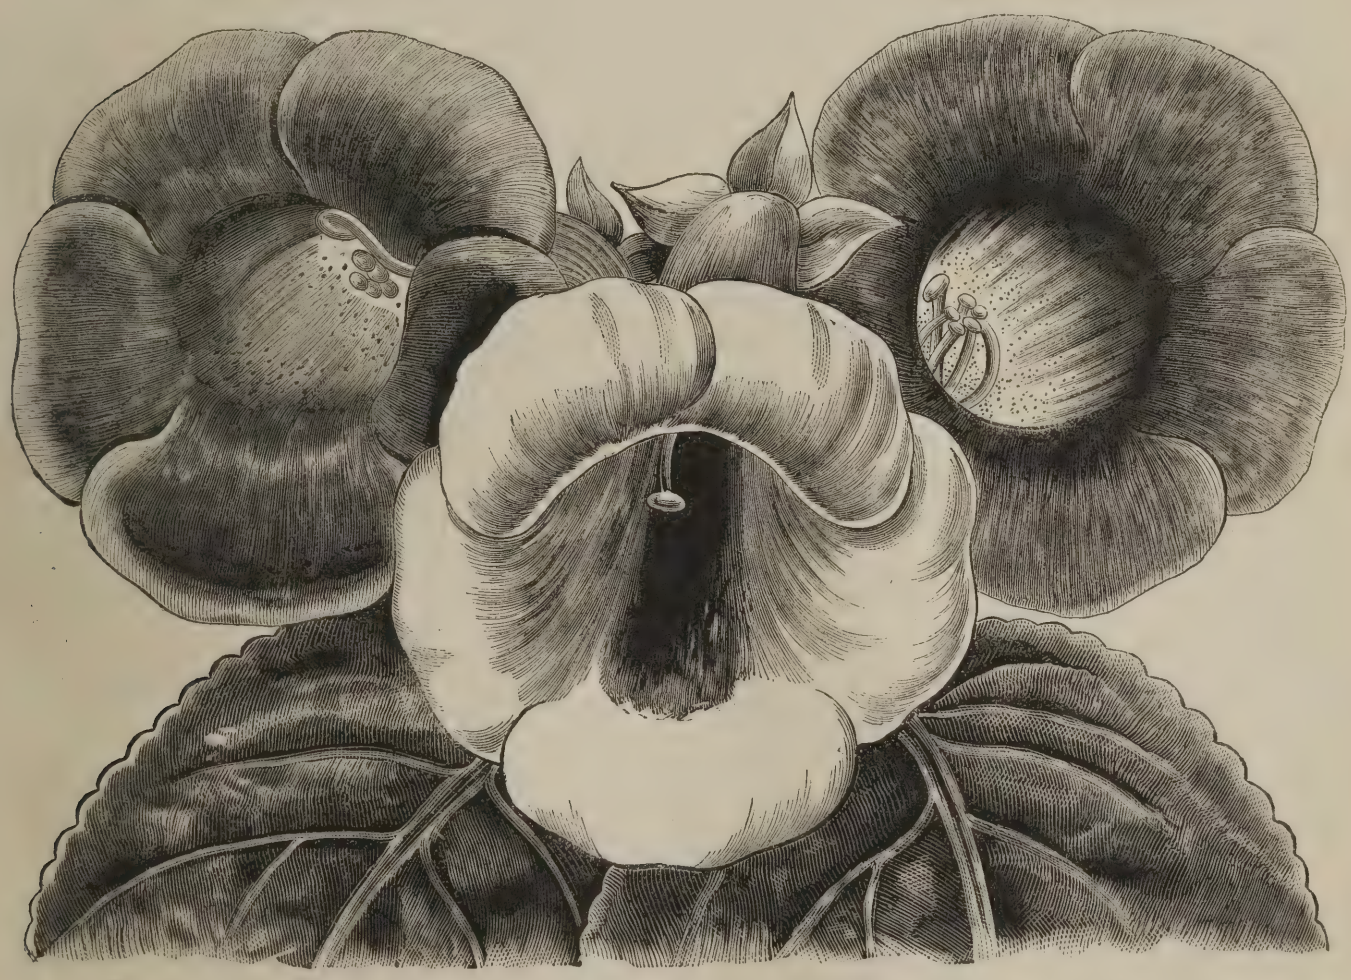
REGISTERED FOR TRANSMISSION ABROAD.

GLOXINIAS.

A SHORT time ago we received a box of cut blooms of Gloxinias from Messrs. Sutton & Sons, of Reading, which were, we think, the largest we ever saw. They were varied in colour, some being pure white, others embracing all shades of crimson, purple, and blue. These were the results of seed saved from time to time from the best hybridised flowers only. The leaves sent with the flowers, too, showed the vigorous habit of the plants, and the good culture they had been subjected to. In regard to culture, Messrs. Sutton remark: "These may be had in bloom almost all the year by judicious management. As cut blooms in the early spring, we know of nothing that has a more beautiful effect in vases, &c. When required for early blooming, those that 'start' first should be selected and carefully shifted on into other pots, and be kept near the glass, as they depend much on light for a rapid and luxuriant growth. A moist atmosphere, with the temperature about 60° to 65°, greatly facilitates the growth of Gloxinias, but they may be grown well in either greenhouses or pits (heated by hot water or manure). The soil most suited to Gloxinias is a light compost of fibrous loam and a little peat and silver sand, and a careful watering with manure water during the growing period twice a week, and when flowering once a week, is very useful. The plants love shade, and at no time should suffer from drought. Storing Gloxinias for their season of rest (that is, in winter) must be carefully attended to, as losses frequently occur during this stage. It is also important that the plants should not be 'dried off' too quickly, but let them rather be placed in a light, airy position, and then by a gradual reduction of moisture the leaves will fall off naturally. The plants or bulbs may then be stored away on a shelf in the shed, in an even temperature of about 50°, each bulb being closely surrounded by Cocoa-nut fibre and peat in equal parts to prevent excessive dryness, which, like too much damp, often causes the loss of the bulb. Besides growing on the same plants from year to year, it is always desirable to have a fresh stock coming on, as the old bulbs may deteriorate after two or three years. This can easily be managed by successive sowings of seed. The seedlings rapidly form strong healthy plants, and from sowings in February and March flowering bulbs will be obtained in July, August, and September, and by sowing again in July there will be young plants to flower early the following spring. One great advantage to be obtained from seedlings is an almost endless variety of colour, for the careful hybridisation of the choicest flowers not only secures the reproduction of those colours, but other fine shades also. At the same time those who prefer to propagate their own bulbs can do so by leaf-cuttings; but except where it is desirable to



GLOXINIAS (LIFE SIZE).

perpetuate any one particular shade of colour, the raising of seedlings is much to be preferred."

VEGETABLES.

CULTURE OF CAULIFLOWERS.

IN the Midland and Northern Counties Cauliflowers cannot be relied upon to stand the winter without some protection. Of course there is nothing so good as glass in some shape, and although I hope to see the time when every cottage gardener who really loves his garden may have his frame or turf-pit, yet at the present time such aids to cultivation are not generally found; but by sowing and planting the early crop in the warmest positions, by frequently adding dry ashes to the young plants to prevent damp settling round the stems, and at the approach of cold, frosty weather applying some thin shelter that will protect without weakening, Cauliflowers may easily be wintered. A few evergreen branches staked amongst the plants, or laid over them without touching them, will generally be sufficient; fronds of Bracken will answer even better, or a few dry leaves scattered amongst them will also be effective. Simple contrivances are often more serviceable if put on and removed at the right time than more elaborate protection thoughtlessly used; it should always be borne in mind that protection, except in the most severe weather, is neither necessary nor desirable. By adopting the means I have just recommended there is nothing to prevent the humblest cottager having his Cauliflowers ready in June, and a man of limited means within reach of a town will find this a very paying crop to grow.

Sowing.—Sow from the middle to the end of August, according to situation and season. There is nothing gained by sowing too early, especially where only one sowing is made, on account of the tendency of the early-sown plants to bolt prematurely. It has generally been the custom to recommend such plants to be pricked out at the foot of a south wall to stand the winter on account of the warmth and shelter afforded, but I very much doubt the wisdom of such a proceeding, unless the plants can be shaded from bright sunshine during severe weather, otherwise the extremes of temperature will cause more losses than if the plants had been wintered in some open, fully-exposed situation sheltered in the way I have suggested. The same objections do not apply with so much force to the south side of a hedge, as the constant circulation of air prevents in a great measure any ill effects arising from bright sunshine when followed by frosty nights. After all danger from severe frosts is past, the foot of a south wall is a most desirable situation in which to plant the earliest patch, as they will be free from that alternate thawing and freezing to which they would be exposed in such a position in winter. The Early London is a good kind to sow for early work, and if at the same time just a pinch of the Walcheren and Veitch's Autumn Giant be sown, a succession may be secured without much further trouble.

Planting.—When the young plants are large enough to handle prick them out into some dry, warm bed, bearing in mind the hints just given about the destruction often caused by alternations of frost and thaw during severe weather without the true cause being always suspected. Give them sufficient space, in order that they may form vigorous young plants; not less than 3 in. apart will be necessary, and even more if it can be spared. About the end of March plant them out finally on land that has been thrown up roughly and well pulverised during winter. Draw rather deep drills 2 ft. apart, and plant in the bottom of the drills 18 in. apart. Inexperienced planters often make a mistake in not fastening the plants firmly in the soil, especially where a dibble is used, but in moving any that have been pricked out a trowel is the proper implement to use; but, whether planting with a trowel or dibble, the plants should be fixed in their positions with a moderate degree of firmness, somewhat resembling those they previously occupied. Where this operation is not attended to the plants are a long time before they make a fresh start, and of course valuable time is thereby lost, and some of the plants not unfrequently perish.

After Culture.—The other culture consists in frequently stirring the soil during the early season, drawing a little earth up to the stems each time; liquid manure, if it can be obtained, will pay well for any labour or trouble incurred, and on dry, porous soils, mulching will be very beneficial. For late summer and autumn use sow a pinch of the Walcheren and Autumn Giant about the middle of April and again in the middle of May. These sowings may be planted out direct from the seed-bed whenever and wherever vacant land in good condition can be spared. Usually an open position is the best, but during hot summers, if a cool partially-shaded spot be available, it will be very useful, not only for Cauliflower, but for many other plants. Those who have a frame or a turf pit (the latter especially is a very cheap and useful structure, which will be referred to more fully hereafter) may delay the sowing till September 1, and sow in the pit either in a box or boxes. In such a position the seeds will vegetate with certainty without any danger of the buds destroying the young plants as they come up. Where there is a turf pit, there is no better way of managing young Cauliflower plants in winter than putting them into 3-in. pots when large enough to take from the seed-bed or box, plunging the pots into sawdust or anything similar that will keep the roots moist and comfortable, fitting them as close to the glass as possible without absolutely touching it, ventilating abundantly when the weather is favourable. Any one who has noted how such plants start away when planted out in March or April will not begrudge the little extra labour involved by such operation. Young plants with plenty of healthy roots may be moved without receiving any check, whilst plants pricked out close together in the ordinary way, no matter how carefully moved and planted, must lose a great number of their best roots. I may just mention now that in the early stages of growth soot or lime may be dusted over them occasionally to keep slugs at a distance; and this refers equally to all the other members of the Brassica family. Birds are very partial to their seeds, and wherever the feathered tribes are plentiful some means must be adopted to protect the seeds from their ravages. There is nothing better or cheaper in the long run than covering with old fishing-nets, raised a few inches from the ground on sticks. Cotton or thread crossed and re-crossed over the bed will often scare them for a sufficient time to enable the young plants to get out of their reach. H.

Early Autumn-planted Potatoes.—We planted Ash-leaved Kidneys under a south wall last October (for I like autumn planting), and I have been digging up a good crop, while spring-planted ones were not bigger than Hazel nuts. This shows the advantage of autumn over spring planting for getting new Potatoes fine and early, and although we had a long wet winter and severe frost not one set missed coming up, and yet autumn planting is one of those things that people read of but are afraid to practise. It will be quite the middle of July before spring-planted ones are ready, and that invaluable of sorts, the Beauty of Hebron, will be ready to dig as soon as the Ash-leaved kind. It can be taken up and housed as soon as the Ash-leaved.—G. B., *Shropshire.*

Heartwell Early Marrow Cabbage.—I find this to be a very excellent Cabbage either for early or main crops. We sowed seed of it the third week in July, and put out the plants the second week in September on a well-sheltered piece of ground from which a crop of Onions had just been cleared. We did not dig the ground, but deep drills were drawn in which to plant. Nevertheless, the severity of the winter cut the plants up severely; but as soon as they commenced to grow in spring we loosened the soil between the rows with steel forks, and after a few days earthed them up a little. Under this treatment we cut nice little hearted Cabbages in the end of April; and in the case of each of the first cut ones the stalks have now from four to six little heads on them fit for cutting. Those that promised to make the largest heads were left, and, in spite of continuous drought, they are now very fine Cabbages. I would advise any one who wishes to have good Cabbages for the main crop next year to procure seed of this variety at once. Select an open piece of ground, and sow it thinly in drills, 6 in. apart, about the 20th of July. Keep the soil moist and free from weeds, so that the plants may be dwarf and sturdy; and plant out about the middle of September, so that the plants may get well rooted before winter sets in. I think premature running to seed is oftener caused by checks to growth, such as arise from crowding in the seed bed, than from any other cause. We grow Early York and Atkins' Matchless, for the earliest cutting Early London and Heartwell Marrow, and they are all that can be desired. Any loss by cutting the heads before they attain full growth is fully made up by the second crop of Sprouts, which for supplying a daily demand for vegetables are even more useful than the first crop.—J. G., *Maidstone.*

Sawdust in Gardens.—As one of the correspondents who under the above heading answered the query of "Ferndale" on September 13, 1879, the soundness of such answer "Ferndale" in last week's number, and after a lapse of ten months, calls into question, I will review the whole subject in case any reader who may not have had the previous correspondence under his notice be misled into using a material which is (by itself) useless for lightening clayey soil. On August 30, 1879, query 556, "Ferndale" asks, "Can any reader inform me whether sawdust will assist in lightening clayey soil?" to which I replied, September 13, 1879, answer 556, "Charred sawdust, intermixed with wood ashes, rotten manure, and road scrapings, will greatly assist." "Ferndale" next writes on the subject on July 3, 1880 (p. 209), to say that he procured several sacks, which he shook thickly all over the ground. Then note what follows: He applied "more manure, more ashes, about a bushel of soot, a quantity of salt and fresh-slaked lime worked over several times." After admitting the use of so many ingredients, "Ferndale" sums up by (as I view the matter) giving the sawdust full credit of enriching the soil. Now, I most emphatically maintain from practical experience, as also on the advice of the head gardener of a large estate, better throw your sawdust on the dust-heap than on a garden, the soil of which is clay, for the effect is that the sawdust holds moisture to such an extent as to render matters worse, and in making this assertion I allude to the question of the use of sawdust by itself, and do not embrace a dozen other things therewith, and I am sure all practical gardeners will bear out what I say. I therefore think that "Ferndale" does not act fairly towards those (myself included) who, after giving him the advice he solicited, writes and disputes the soundness thereof, simply on the ground that he used sawdust mixed with a heap of other things. Let him try fairly the use of this article in the manner in which he originally asked the question—by mixing a barrow-load of clay and one of sawdust together in a corner of his garden, turn it over every day if he likes, and if in twelve months' time he can write and say that he has made rich soil of this he will then, and not till then, convince—SOLICITOR'S CLERK.

Sending Plants by Post.—Your correspondent "E. Gill," writing with reference to the sending of plants by post, and their stoppage on account of their being likely to damage the contents of the mail bags, will find the plan of using a tin tube, which can be again wrapped in paper and the enclosures being kept safe by sealing the ends, to answer the requirements of the Post Office, and be the most efficient protection for young plants or Ferns that can be adopted. I recently received from the midland counties some seedling Primulas sent in the manner I have described, and they came to hand in capital condition. Whilst writing on this subject I would desire to call the attention of readers who forward flowers through the post to their friends to the very objectionable though common method of enclosing flowers in card-board boxes such as are used by drapers, the effect being to cause their ruin and bring disappointment rather than pleasure to their recipients. The senders of flowers, desirous of keeping their specimens in good con-

dition, surround them with moisture, either in the way of Moss or leaves, the effect being to not only dissolve the adhesive matter which was used in the manufacture of the cardboard box, but to cause it in very many cases to entirely collapse. This cannot be otherwise, and will readily appear if your readers will only think of the numerous and various kinds of parcels conveyed by the Post Office, and which are heaped one on another into mail bags. Flowers may be sent in the best condition in small wicker baskets or tin boxes such as are sold with biscuits. The cost is nominal, and the pleasure of feeling that our cherished blossoms have reached our friends safely will counterbalance any extra cost.—Postal. [We quite agree with our correspondent's remarks. We have much experience of bad packing. Our readers who send us plants to name often pack them in the most slovenly manner possible, and when they reach us they are smashed to pieces.—Ed.]

ROSES.

OLD AND NEW ROSES.

Some few years ago an argument went through the gardening papers as to whether the old-fashioned cluster Roses or the newer Tea climbers were the more beautiful and effective. My blush climbing Rose began to bloom this year about Midsummer day; so did my Gloire de Dijon. The cluster has gone on bearing hundreds of blossoms; the very dark calyx and lovely pink buds are perfection. There are quite a hundred and fifty Roses varying from deep pink to pale rose and white on the bush now, and quantities more to come. The Gloire de Dijon was also splendid, but the blossoms are quite over now; plenty of buds coming, but there have been no flowers for some days. I put a flower from off each bush in a specimen glass together, and they were equally beautiful. Therefore I think every one should grow both the old sorts and the new. The common white, with its lovely buds and delicious perfume, is running all over a wall and blooming very freely. My China Roses are not doing much; they do not like the east aspect, I fancy. This year, when the rarer Roses are very late or failures, the old-fashioned climbers are the more acceptable. In some years my Céline Forestier bears numerous clusters of lovely large lemon blossoms and exquisite deep red buds. This year I do not yet see a single bud; I shall, therefore, plant a cluster Rose by its side this autumn. Mark.

Treatment of Budded Roses.—Under favourable circumstances, a bud generally gets firmly united in about five or six weeks, and if the growth beyond the bud is not cut in the bud generally remains in a dormant condition. Some few buds it is impossible to keep in a dormant state—they will start into growth whether you wish it or not. In this case, when the bud has grown a few inches, it is better to reduce any wild growth from the Brier at once and try to make as much wood as you can from the pushing bud. Some buds grow and only make a few inches of weakly unripe wood; these are in great danger of being killed in winter. The best way is to nip out the top in the autumn as soon as it has grown about 6 in. This will cause the sap to concentrate about the rings of the bark, and in the ensuing spring it will throw out side-shoots for the formation of a head. It is always best to keep the buds in a dormant state, and this can only be managed by allowing as much wild growth as possible to remain on the Brier until the sap goes down about the end of October or November. About the 20th of November, not earlier, all the wild growth of the Brier may be cut away, leaving only about 6 in. of wood beyond the bud; all side branches may be cut in close. This winter-pruning of budded Briers is necessary, otherwise any weight of snow lodging on the wild growth would break down the shoot and destroy the bud. Budded Briers are very liable to accident from wind, and often break at the place where the cross-cut was made when the bud was inserted. In consequence of having had so many accidents from this cause I have long since discontinued making the cross-cut. I now only make the long incision, and insert the bud with a piece of flat ivory filed down to a bluntish point, like a very flat lead pencil. Such an instrument can be easily made from the broken handle of an old razor. Since I adopted this plan I have never had an accident from the Brier shoot breaking near the bud. About the end of March all the budded Briers must undergo the operation of pruning; the portion of wood left in November, when all the wild spray was cut away, must now be entirely removed, except one bud just above the inserted bud; this one wild bud must be left on the shoot which was worked, and this is called the sap bud, its office being to draw the sap upward, and help the pushing of the inserted bud. When the sap begins to flow freely, it is directed to the one wild bud, which hastens the completion of the union where the incision was made, and the inserted bud, which has remained so long in a dormant state, breaks strongly, and soon commences to grow in earnest. If no sap-bud was left, the inserted bud might not start so readily, and the stock, in order to get rid of its sap, would commence throwing out side-shoots and suckers from the root. When the bud does not start into growth after receiving the pruning and treatment above stated, it is a sure sign that some growth is going on under ground—probably a strong sucker or two are starting from the Brier root. If anything of this sort is suspected, get the garden fork and loosen the soil a little, when you will probably find the enemy, which must be promptly removed; all side-shoots proceeding from the stock must also be removed. When the Rose has grown 3 in. or 4 in., a stick about 2 ft. long must be tied to the Brier in two places, and it must stand well up above the growing bud; to this support the Rose must be tied, as the growth proceeds, with worsted, which is better than bast, as it does not rot in winter, and allow the snow to weigh down and break the yet tender growth of the Rose. Occasionally we find a bud very obstinate, not starting into growth in the spring; sometimes it will start at midsummer, and I have seen a few cases every year where the bud actually refuses to commence growing until the following year; but these cases are exceptional. It is, therefore, unwise to cut away the sap-bud until after midsummer; but the points of the shoots may be nipped out occasionally, by way of coaxing the inserted bud into growth. Watch the stocks closely until midsummer, and rub away any wild growth that the Brier may make as fast as it appears, in order that the full flow of sap may be directed to the growing Rose. When the bud has grown 6 in. nip out the top, and side-branches will be thrown out, and a head soon formed which will bloom in autumn.—H. T.

Window Ornaments.—I was short of flower-pots one day, so, seeing a small drain-pipe lying in the potting shed, the idea of converting it into a flower-pot of some kind entered my head. I first knocked a round hole in the centre of the pipe, and took two rather stalky Geraniums, and inserted one in each end, so that their roots would not be far from the centre hole, which hole I made for the purpose of watering the plants. I then filled in with earth, putting a half-moon shaped piece of virgin cork into the ends to keep the water from running out too much; then I planted some Nasturtium seeds in the centre hole, and ran a piece of wire through to hang the pot up by. I have made several others; some have Sweet Peas and creeping plants hanging from them, which look pretty and are much admired.—H. S. S.

Camphor for Killing Slugs.—A short time ago I placed some powdered camphor in a Melon frame to destroy some ants, and on examining the frame on the following morning I found several large slugs in a dying condition; this induced me to try the camphor in other places where the slugs had been troublesome, and I have invariably found the experiment successful.—James Simmonds.

An Easily-made Fumigator.—Having a small greenhouse which was infested with green fly, especially the Roses, and not having a fumigator, I constructed one which answered well. I got 1 ft. of india-rubber tubing; to one end I attached a clay pipe, so that the head fitted exactly inside the tube; to the other end I fixed a mouthpiece made of wood, which also fits inside the tube. That being completed, I light the pipe and blow through the mouthpiece, which sends a continual volume of smoke on the plants desired to be fumigated. I find this works admirably well on specimen plants.—E. H. McM.

TROPÆOLUMS AND DATURAS.

There are few plants more peculiar in their requirements and capricious in their likings than Tropæolum speciosum. In some places, especially in the northern parts of this island, it grows with great freedom, demanding but little care at the hands of the grower, whilst in many localities the greatest amount of care and attention will not induce it to make anything like satisfactory progress. In many cases, however, growers have only their own impatience to blame; for this plant, unlike the generality of climbers, cannot be pushed along into growth at a rapid rate. As a rule, even when in the enjoyment of the most favourable conditions, it requires to be established at least three years before it shows signs of attaining luxuriance. Then it will suddenly rush away into growth in a manner that will at once surprise and delight the grower. At the present time, when so many free-growing flowering plants are at the disposal of the horticulturist, this waiting for effect cannot be endured, the consequence being that one of the most beautiful ornaments of our gardens is seldom seen in anything like good condition. The situation chosen for this handsome creeper should be partially shaded, and where a certain amount of atmospheric moisture prevails during the hot summer months. The soil should be free, deep, and tolerably rich—a good compost, consisting of half loam and peat with the addition of a little leaf-mould. Some recommend the admixture of well rotted manure. I would not, however, counsel the employment of any strong manurial agent, preferring to use a soil which might err on the side of lightness and poverty, but in which the roots might be depended on to remain in good condition. The great point is to secure a vigorous root action, any deficiency in the way of nutriment being easily supplied by means of liberal top-dressings. Plant the tubers some 6 in. deep in the soil and await the result patiently. As soon as growth appears above ground place some twigs for the shoots to ramble on. As before stated, the first year but little growth will be made, and in all probability not a great deal the second. During hot weather a cool, grateful atmosphere may be maintained by well sprinkling the foliage and soil around both morning and evening.

Tropæolum polyphyllum is by no means of such difficult culture; it requires a free soil, demanding at the same time perfect drainage. It succeeds well on a rockwork, for which position its habit of growth better fits it than for training to trellis-work. Plant the bulbs about March, choosing a sunny, well-drained situation; or if such does not naturally exist, form a raised mound of stone and earth, setting the tubers somewhat deeply in the soil. If the tubers are strong they will give a good display of bloom the first year.

Datura chloranthe.—Seeds of this should be sown either in the autumn and wintered in a cool greenhouse, to be potted off and grown along in a cold frame early in spring, or it may be sown about the beginning of March. It will thrive in the open air in any free soil, but gives most satisfaction when afforded some shelter. J. C.

Byfleet.

Phlox Drummondi.—Here is what is known as a tender annual, that is, for all practical purposes, a hardy bedding plant, and a most effective one, too; its great requirement is a fine soil into which its roots can make a free growth. I have recently seen a bed the soil in which was made up of loam, manure, leaf-mould, and a quantity of finely-sifted mortar rubbish. During dry weather the plants were watered freely, and they now cover the bed completely, and are throwing up remarkably fine trusses of flowers, double the size usually seen. This Phlox must be in rich soil to produce fine flowers, and it is a mistake to have it in poor soil; a good mixture of kinds is essential, that is, the beds should contain plants having flowers of varying and, let us add, striking colours. I saw a bed a few days ago in which the prevailing colour was a pale, indistinct lilac, with scarcely a dash of any brightness to break the monotony. Phlox Drummondi is much to be preferred to the Verbena as a bedding plant, and the rich blood-crimson P. grandiflora splendens is most effective. This variety especially should be used for bedding and border purposes.

Tuberous-rooted Begonias.—When planted out in a light rich soil on a sunny, warm border these do well, and flower profusely, and their blossoms prove more durable than when the plants are in pots in the heated atmosphere of a greenhouse. It is an interesting process to raise a few of these Begonias from seed. It is easy to get a good strain of seed from any seedsman, and it should be sown in a pan or box of light sandy soil, and then placed in a gentle bottom-heat with a piece of glass over it. As soon as the seedlings are large enough to handle, they should be pricked off into pots and grown on as fast as possible. Tuberous-rooted Begonias make good exhibition plants, but they require to be conveyed with much care to the place of show, or they will shed their flowers. It may not be generally known that B. Weltoniensis makes an excellent town plant, growing well and flowering freely in confined places where other plants will fail.

Mauve Beauty Stock.—This magnificent Stock is the result of several years' careful selection, and has commanded general admiration tor its great beauty. It has a true pyramidal, free-branching habit, and forms a dense pyramid of flowers; colour, a lustrous pale mauve; it is a grand variety for exhibition purposes. It can be grown as an intermediate variety if sown in August and September.

Canterbury Bells.—The are some beautiful forms of these, the flowers of which are very large, and in many cases double. They vary in colour from pure white to blush, lilac, pink, rosy-purple, violet, and blue. They rank amongst the most attractive of border flowers, because they bloom so freely and so continuously. Then there is the form known as C. Medium Calycanthema, in which the calyx is coloured and of large size—in the form of a disc. In this section we get white, cream, delicate mauve, and blue flowers. They are very attractive, but one could wish they were a little less lanky in growth. In this respect the new strain of Canterbury Bells decidedly gets the best of it. It is best to sow the seed in March and April, in order to get the plants strong before planting-out time, but some may be sown at once if the plants be pushed on into growth as soon as possible.

Pentstemon heterophyllus; flowers lilac.

Eschscholtzia.—The beautiful forms of this glowing annual, which we have recently seen, are indeed great acquisitions; the rich reddish-orange of Mandarin, and the unique form of the double crocea, are accessions of real value, and, with crocea, alba, and the orange aurantiaca, give us a batch of most attractive flowers. What is known as E. rosea is decidedly pretty, but is so apt to revert to the white form from which it sprang. Some jagged-edged sports, named dentata, are really not worth growing, and have become almost lost. Eschscholtzias are very effective when treated as biennials, the seed being sown in well-prepared ground in September to bloom early in spring; the plants get well established, and send their roots readily into the soil during winter, and then bloom with dazzling splendour in May.

Pansies.—The late rains are greatly helping Pansies, which are now throwing up young growths from the roots. These may be taken off for cuttings as soon as large enough, and put into a well-prepared bed under a shaded north wall. Such a bed as this is of great value at this season of the year for striking cuttings of such plants as choice Antirrhinums and Pentstemons, Pansies and Violas, Wallflowers, Rockets, &c. I have such a bed as this, which is raised about 9 in. above the ground level. At the bottom is a layer of brick rubbish, and over this another of coarse cinder ashes, and above that some pieces of green turf with the Grass downwards. This was trodden down firmly, and then filled up with prepared soil to the depth of 4 in., made up of fine sifted loam and leaf-mould, a little rough Bedfordshire sand, and some finely-sifted cinder ashes. This is well mixed together, and the whole placed in the bed and firmly pressed down; then I add a thin layer of very fine cinder ashes on the top. In such a compost cuttings of the plants I have named strike freely, and the cinder ashes seem to keep the soil open and slugs and other vermin at bay. Cuttings of Violas may be similarly treated. A little top-dressing greatly helps the production of strong young wood, from which cuttings can be made.—D.

HOW TO GROW PENTSTEMONS.

PENTSTEMONS succeed in any good soil, but in a good loam enriched with manure and leaf-soil they are certain to do well. They can be planted out singly or in groups in the mixed border or in beds, in which the various colours become charmingly blended.

The Pentstemon is increased both by means of cuttings and seeds. The former method must be resorted to in order to increase any particular variety. Cuttings should be taken in August or early in September from the young growths thrown up round the main stem, and they should be put into a prepared sandy bed, on a shady border, under a hand-glass, or in boxes or pots placed in a cold frame. They root readily, and those in boxes or pots might be wintered in this way, and not transplanted till spring. Those struck on the border should be lifted and potted, or planted out in a cold frame for the winter, or transplanted to the open ground in a well-prepared bed, and protected with a little litter or branches of evergreens during severe weather. Under general circumstances the young plants should not be planted out till the March or April following. When it is desired to increase the stock of any one or more varieties as rapidly as possible, the store pots of cuttings rooted in autumn should be taken into a gentle bottom-heat in spring and induced to grow; and if the young growths be taken off as soon as they are 2 in. in length, and put in pans of sandy soil in the same temperature, they will quickly strike, and by May and June, if properly treated, will have grown into healthy plants. Seed only of the best varieties should be sown. The Pentstemon is a very free seeder, and there is no difficulty in obtaining some. In saving seed for sowing, only the very finest varieties should be selected for the purpose, and those showing novelty of character—for variation is always a most acceptable characteristic—and such flowers can scarcely fail to yield something well worthy of cultivation.

The seed should be sown in February or early in March in a gentle heat. It will quickly germinate, and when the plants are large enough to handle, they should be pricked off into shallow boxes, and after a time hardened off in a cold frame. Here the plants can remain till the end of May or later, according to their size, and then be planted out in well-prepared beds. A generous soil will serve to bring out as fully as possible the quality of the seedling flowers. When they flower, which they will do by August and September, any varieties of extra good quality should be marked for propagation by cuttings or for seeding from, while the inferior ones will do for the mixed border. If the bed of seedlings be allowed to stand for another season (and it is always a good plan to do this), the seed stalks should be cut away as soon as ripe, the bed cleaned, top-dressed with leaf-soil and short manure in spring, and it will yield a plentiful harvest of flowers the following summer.

The following are twenty-four beautiful varieties that may be obtained from any nurseryman making a speciality of the Pentstemon, viz.:—Agnes Laing, Apollo, Apollon, Bridesmaid, Calliope, delicatissimus, Euterpe, Flora, George Sand, H. M. Stanley, Mons. Clément, Madame Louis Schmitzer, Monarch, Novelty, Polly King, Giant, Iona, Stanstead Rival, W. E. Gumbleton, W. P. Laird, Secretary Curzon, striatus, Volunteer, and Yeoman. Of the species, P. azureus, P. ovatus, P. Jaffrayanus, and P. heterophyllus (represented in our engraving) well deserve cultivation. The flowers of P. Jaffrayanus are of a charming hue of blue, which is only to be found in a very few of the improved varieties. P. heterophyllus bears pinkish-lilac coloured blossoms.

Forget-me-not in Derbyshire.—Myosotis grows as the weeds of the field in the limestone regions of Derbyshire. I applied some Derbyshire lime to mine and had abundance of bloom.—W. W., *Belper*.

Petunias.—Beds and ribbon lines of these are now very effective. For decorative purposes the small, finely-formed, striped section is to be preferred; the growth is dwarf, compact, and somewhat spare, while the flowers are produced with great freedom. There is a section with a more robust growth which produces large but looser flowers than the foregoing, flowers that hang their petals and have a flabby appearance; this section does not bloom so freely as the foregoing. Sometimes persons who grow Petunias are apt to be disappointed because the flowers come self-coloured; this is frequently the case in regard to their early blossoms, but the later ones invariably break into the correct striped form, and then all sense of disappointment is lost in the contemplation of so much beauty. During dull, wet weather the flowers will come self-coloured, but let a hot, sunny day follow, and then the striped character flashes forth again with charming effect. Petunias, both double and single, make fine exhibition plants; they succeed uncommonly well in the west of England, especially the single varieties, where plants can be seen having from fifty to one hundred flowers—and very fine flowers, too. There is nothing like them to be seen round London.—D.

Mimulus.—I give my experience of Mimulus, hoping that it may do good. The first Mimulus that came into my possession was the old M. Fraseri. It has a very pretty flower, but when not in flower looks rather dowdy; it is a good bedding plant, showing its flowers to perfection, for they will stand wind and rain; it is very easy to propagate. The double Mimuluses are very pretty; one of the prettiest I know has a pale Hose-in-hose flower, and possesses the advantage of being very pretty when out of flower, its small serrated leaves looking more handsome than those of M. Fraseri. I have propagated this outdoors sheltered from the rain; the name is M. Duplex. The best Mimulus I have seen is M. tigrinum.—G. SIETHORP.

Hardiness of Indian Pinks.—Two years ago I purchased a packet of seed of these Pinks, also one of Japan Pinks, sowed both out-of-doors, and they have been in my garden ever since without the slightest protection. Last spring I gave them the best bed we had, hoping for a grand display, but they did very indifferently, and went somewhat out of favour. This spring, and up to the present time, they have bloomed splendidly, and those friends who were loudest in their condemnation last year are almost as loud in praise this. The Japan ones are very interesting; the blossoms are but small, but well thrown up above the leaves. When the sun shines on them they expand and seem to

revel in it; but at night they close up their little heads, and, if I may use such a term, appear to go to sleep. Mine are pink, white, and crimson; last year there were a few different colours. For a rock plant I have seen few things to beat them, and they have the advantage of being green all through the winter. I may add that my garden is very exposed, standing quite 12 ft. above the road, and exposed to strong north-east winds. My plants have been shifted from place to place frequently, so that in these respects they are not at all favoured.—T. C.

Propagating Clematis.—In the spring of 1878 I bought several of these plants specially to try whether I could propagate them. The following is the course adopted and the result: 1st July, 1878, I put in two cuttings of the Queen Clematis, two joints each cutting, measuring between 2 in. and 3 in. each, and dibbled them in a 2½-in. pot in light garden mould, no sand or shade, sank the pot in south border and put hand-glass over pot, kept them rather wet; after they had been in a month I put a stone under the glass to give them air day and night. I took the pot up on August 19, and found the roots coming through; November 21 they were two very nice plants, and nearly as large as the parent plant I bought June 10 same year. One of these I planted in May this year on north wall, and is a promising plant. August 19, 1878, I dibbled eight cuttings of Clematis M. Albani in a 4½-in. pot; October 7 slipped them out to see if rooted, and found they had; October 21 potted them in 3-in. pots, treated as above; planted one on south wall last year, but now rather backward; another I planted in May this year against south wall, and is growing very fast considering the weather. All the attention I gave them was to keep them wet, and look morning and evening for slugs, and press down worm-casts in the pots; watered with cold water.—C. S.

Double-flowered Pæonies.—These constitute at the present time one of the chief features of the hardy flower garden, and too much cannot be said in their praise. They possess an exquisite perfume similar to that of Tea Roses, and their large handsomely-formed flowers possess a striking variation of colour, varying from the deepest crimson to the purest white. In Mr. Parker's nursery at Tooting, which contains the finest collection we know of, there are upwards of seventy sorts which are more or less distinct, though necessarily there is a strong resemblance to each other in some of the kinds. The majority appear to be of Continental origin, a circumstance owing no doubt to the climate there being more favourable for perfecting the seed; hence the greater number of the sorts bear foreign names. Without making a long list of the best varieties we append an enumeration of a few of the most distinct. Among the best white kinds are Alba sulphurea, Candidissima, Marquis de Lory, Nivea plenissima, and Queen Perfection. Of pinks—Souvenir de l'Exposition, Oberlin, Madame Lemoine, Louisa d'Estrees, and Dr. Brettonneau. Of crimsons—Ambroise Verschaffelt, Henry Demay, Souvenir d'Auguste Miellez, Victoire d'Alma, and Augustin Dhour. Such sorts as the following would fill up, as it were, the intermediate shades in making a representative selection, viz., Eugène Verdier, Madame Calot, Madame Serret, Triomphe de Paris, Prince de Salm Dycke, Madame Vilmorin, and Gloria Patria. All the above grow to much the same height, about 3 ft., and thrive well in any ordinary garden soil. All the varieties appear to have sprung from the old P. officinalis and its varieties, and more particularly from the Anemone-flowered kind (anemonæflora), the flowers of which have an outer row of large or guard petals enclosing numerous small petals.

Gladioli and Marigolds.—A slight mulching of 1 in. or so of rotten manure over the surface of Gladiolus beds will benefit them, and will help to keep the soil moist and the roots cool, which has a considerable influence in preventing the disease. Tie the plants up before they get so large as to be acted upon by the wind, using for this purpose a neat stick, such as a stout dry Willow or Hazel, the thickness of one's finger; and be careful, when inserting it, not to thrust it down so near the roots as to injure them. There are few more handsome and continuous border flowers than the French Marigold, blooming, as it does, from the present time until it is cut down by frost. Those who happen to have a good strain of striped or edged kinds should now, as the plants come into flower, remove all that are single or semi-double. This not only greatly improves the appearance of what are left, but is also necessary in saving seed, which is deteriorated by the presence of poor flowers. No seed should be saved except from the best double blooms. If the strain is too dark, or does not possess a sufficient number of the rich yellow-striped forms, or is deficient in size, a few plants of the African Yellow should be grown near or amongst them. These will cross with and improve the French varieties, both in colour and size; but this must not be repeated every year, or they will become too yellow.

Tom Thumb Fuchsia.—This is a pretty little plant, somewhat resembling F. gracilis, but smaller, rarely exceeding 1 ft. in height, and forming spreading little bushes from 1 ft. to 1½ ft. in diameter, each tiny shoot being ladened with crimson-sepalled, purple-petalled flowers and bright buds, as suggested in the annexed engraving, which represents the top of a flowering shoot exactly of the natural size. The plant does not appear to be generally grown in England, but here, in Ireland, the naturalised home of the Fuchsia, it is more common, although nowhere so plentiful as the F. globosa, F. Riccartoni, and F. gracilis. Little bushes of all the kinds mentioned are charming ornaments to the rockery and herbaceous border, or even for isolated positions on the lawn in sheltered places. Cuttings inserted in any light garden soil about July, and sheltered by a hand-glass or cloche, root freely, and form pretty little plants for flowering the following year. As a pot plant it is very desirable, and if cuttings be forwarded in a cold frame pretty little specimens may be obtained, and are very useful for summer and autumn greenhouse or window decoration. Were it more readily procurable it would prove to be a most desirable plant for the cottage window. Whether this Fuchsia is a puny form of the hardy F. Riccartoni, or a pure species hitherto overlooked in the great struggle after "new and rare" plants, is a question of merely secondary importance. The main point is that it is one of the most distinct and effective of all hardy kinds of Fuchsia, and as such worthy of a far more general distribution than it now enjoys. It would probably be obtainable in Irish nurseries, such as those of Mr. Smith, of Newry, or Messrs. Farrell & Sons, Chapel Street, Dublin.—B.

Tom Thumb Fuchsia (a hardy plant).

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

July 19.—Potting Daphnes into a mixture of loam, peat, charcoal, bones, and sand; also Amarantus and Dracænas, and put them in warm house; digging up Rivers' Early Ashleaf Potatoes; thinning Mignonette in pots, and clipping Cerastium edgings, and preparing borders in which to put Pelargonium cuttings; sowing black-seeded Brown Cos Lettuce for winter use; potting on small Cinerarias; planting out Lettuces and Endive; earthing up Cardoons; pulling up pickling Onions and spreading them out to dry; sticking Peas and getting them earthed up, and topping those which are growing above the sticks; getting large rough frames ready for sowing late Peas and late Dwarf French Beans, so as to protect them from the early autumn frosts; nailing and tying in Roses on walls and picking off all dead flowers; hoeing and weeding amongst Strawberries, and cutting away all runners that are not required for planting.

July 20.—Layering Strawberry runners with which to make new plantations; digging land for Turnips cutting Lavender, weeding and thinning Chicory, and earthing up Cucumbers; Sowing Laxton's Omega and Unique Peas; budding Roses, and giving them a good mulching with rotten manure; hand-weeding herbaceous borders and giving them a general clean up; watering Celery; also Leeks, Parsley, Turnips, &c.; gathering Black Currants for preserving; lifting early sorts of Potatoes and spreading them out in the sun to ripen them well for seed next season.

July 21.—Potting Abutilon Boule de Neige; also Primulas, and afterwards placing them in a close shady frame until well rooted; planting Coleworts on land cleared of early Peas, making the holes with a crowbar, and afterwards watering the roots well in; staking Petunias and Rhodanthes; dressing Apple trees with paraffin to kill American blight; putting in Pink and Carnation pipings under hand-lights; earthing up Celery when the soil is dry and in workable condition; weeding and picking over carpet bedding borders; making up new Mushroom bed in the open ground; looking over Marrows and Gherkins, and closely stopping them all; digging up, manuring, and watering borders previous to sowing with Wheeler's Imperial Cabbage, and stopping and nailing in the shoots of Tomatoes on walls; nailing in all the leading shoots of Peaches, Nectarines, Apricots, and Cherries; looking over Cucumbers and Melons, watering them and stopping them where required, and renovating the linings round all manure frames.

July 22.—Potting Sir Harry Strawberries for forcing; putting in cuttings of Lady Plymouth Pelargoniums for pot culture; watering herb beds and Pear trees; filling pits with fermenting material in which to plant Cucumbers; digging land for main crop of Spinach; potting on Celosias, Coleuses, and Begonias; picking off early blooms and pegging down the branches of exhibition Balsams; stopping the laterals through all Vineries and giving late houses a good soaking with guano water inside and out; staking and tying in plants on borders; training out and pegging down bedding plants and clearing away decaying leaves and flowers; thinning out Turnips, Carrots, and Spinach; cutting back Laurels in pleasure grounds where overgrowing walks; watering Lettuce and Endive beds, and hoeing amongst all growing crops.

July 23.—Putting in Phlox and Pelargonium cuttings; weeding, hoeing, and afterwards mulching Aster beds; stopping and tying out Dahlias and thinning out the blooms where required for exhibition; cutting back Ivy on walls where overgrowing windows; clearing off Peas and manuring and digging the ground ready for autumn Cabbages; getting new mould into cold pits and pricking them out with Parsley roots for winter use; cutting back the breastwood and nailing in the leaders of Plums and Pears; potting Pinks and winter-flowering Carnations; sowing Sir Joseph Paxton French Beans under the protection of a wall; earthing up Cauliflowers; planting Paris Cos Lettuce.

July 24.—Pricking off a late batch of Primulas and Cinerarias; transplanting Silenes and Forget-me-nots from seed beds, also seedling Violas; planting out a large breadth of Savoys for small heads, also Coleworts; mulching late Peas with rotten manure; giving Scarlet Runner Beans a good soaking with manure water; weeding and cleaning Box edgings in garden walks; watering Celery, Cardoons, Cauliflowers, and Tomatoes; potting Caladiums and young Begonias; sowing Nemophilas for pot culture; also Ten-week Stocks, Phlox Drummondi, Lobelias, Rhodanthes, Schizanthus, and Clintonia pulchella; also sowing more Lettuce, American Cress, French Beans, and Spinach; watering Rhododendrons likely to suffer from drought; putting in cuttings of Centaurea and Artemisia; tying up dried Basil and putting it in paper.

Flower.

Verbenas, Petunias, Heliotropes, and Ageratums are growing straggly and require pegging, in order to preserve uniformity of height and truthfulness of design. Stake Sweet Peas, top back a few inches the earliest flowered ones, in order to induce a second bloom, and clip over, with the same intent, annual flowers that have produced a first bloom. Virginian Stocks, Schizanthuses, Nemophilas, and Eschscholtzias are all amenable to such manipulation. Lawns must be frequently mown and swept, using the roller assiduously in damp weather. Daisies, Dandelions, and other objectionable weeds in Grass must be eradicated on every favourable

opportunity, taking care to do the least possible injury to the turf. A slight sprinkling of salt is beneficial to Grass at this season; it should be applied in wet weather. Those who grow common spring flowers, as Daisies, Pansies, Arabis, Aubrietias, Forget-me-nots, &c., may now sow seeds in cold frames, pricking them out when ready; they will thus make good strong plants by the time the bedding plants have played their part. The above may also be propagated by means of cuttings or root division; indeed, seeds of most perennials may now be sown in nursery beds, and a few annuals in borders for late flowering. A mulching of well rotted manure given to beds of Asters, Stocks, Zinnias, Helichrysums, &c., will materially assist in developing their flowers and deepening their colour.

Asters.—Do not allow these to grow too thickly, or the flowers will be small and the plants will soon become exhausted. If they show signs of weakness through the ground not being rich enough, assist them with manure water. There is no plant less able than Asters to bear the effect of aphides, whose presence is easily detected by the leaves curling up. A good washing with Tobacco water is the best remedy, and this should be applied as soon as the insects are detected, or the plants will be surely spoilt. The tall-growing kinds, if at all in an exposed situation, will require a small stick and tie to each plant.

Lilies in Pots.—These will now require attention; the necessary supports, consisting of a single stick to each stem, should at once be put to them. Where there are several bulbs in a pot it is necessary to be careful as to how the sticks are inserted, otherwise the bulbs will get injured. Where the plants are strong and the pots comparatively small for the number of bulbs which they contain, the roots will by this time have permeated every particle of soil. Liquid manure will be of the greatest possible benefit in enabling them to retain their lower leaves in a green healthy state until the flowering is over. Another matter is to keep them scrupulously clear from insects, as there are few plants that sooner suffer from neglect in this matter. L. eximium, the earliest bloomed plants of L. auratum, and others that have done flowering, so far as their future well-being is concerned, require to be just as well treated in the matter of attention as to water, so long as their leaves keep green, as they did previous to blooming.

Phloxes in Pots.—These should be supported by means of stoutish sticks, and it may be necessary to plunge the pots in Cocoanut fibre refuse or some similar material, to prevent their being overthrown by the wind. They must be attended to with regard to watering, and they will be benefited by liberal supplies of manure water up to the time when the flowers open. All such subjects out-of-doors require the same attention. The best time at which to propagate Phloxes is early in spring, but there are side-growths to be obtained now, which may be inserted either in a shady border or in small pots.

Pentstemons.—These are just coming into bloom, and the growing shoots must be carefully fastened to sticks. Pentstemons have a good effect in mixed borders and also in beds. Cuttings of them may be put in now if the object be to attain a large stock of plants, but the best time is September or early in October.

Delphiniums.—These are now in full beauty, and well repay the cultivator for any care which he may have taken with them. Nothing now is required except to see that the flowers are not injured by the wind.

Pits and Frames.

Where pot plants are grown in pits they must be kept well up to the glass, or they are apt to become drawn. Plants in such structures are more liable to get neglected as regards water than in houses, where they can be more readily examined. Under such circumstances, too, insects are more likely to escape observation than in more open quarters, and therefore must be looked after more closely. In addition to supplying pot plants with sufficient water at the roots, it is also requisite, while active growth is progressing, to keep the floors of the pits or frames on which they stand well and regularly moistened, for if this be not attended to the atmosphere during hot sunny weather becomes so dry that healthy growth is out of the question.

Fuchsias, &c.—Some cuttings should now be put in to keep on growing slowly through the winter; these will give much more satisfaction than old plants, which, as generally managed, are thin and scraggy, showing too much of the old wood, whereas a well-grown Fuchsia should be profusely furnished with young shoots covered with flowers and healthy foliage. Fuchsias, Petunias, and zonal Pelargoniums that are intended to flower through the autumn should receive all requisite attention, and be kept in a blooming condition so long as there is sufficient atmospheric heat and light, as from this time forward there are comparatively few greenhouse plants to maintain a display.

Hardy Fernery.

Ferns, unless well looked to and properly supplied with water, both overhead and at the roots, will soon present a shabby appearance, as thrips are sure to attack them. Where bulbous plants and others of a semi-wild character are grown in suitable portions of the hardy Fernery, as they always should be, the less interference they receive in the way of trimming or removal of leaves the greater will be their strength and capacity for blooming next year. It is a great mistake, for the sake of appearances, to denude such plants of their foliage, as is frequently the case, long before it has died off and ceased to be useful, the effect being to stop the maturation of the bulb or crown of the plant, as the case may be, and prevent the formation of flowers.

Shrubbery.

Flowering shrubs, as soon as they go out of bloom, should have dead and decaying flowers removed, and when necessary the plants should be cut back. Box edgings may also now be trimmed, and all Sweet Brier and Privet hedges may be cut. The common Yew is an excellent hedge plant, but it is of slow growth. There are, however, several other hardy coniferous trees to which this objection does not apply, such as Cupressus Lawsoniana, Thuja Lobbi, Thujopsis borealis, &c., all of which are well suited for ornamental hedges or screens. Where such already exist the present is the most suitable time for cutting, or rather clipping them; but when such hedges or screens consist of large-leaved plants, such as the common or Portugal Laurel, it is then advisable to prune with the knife, in order to avoid, as much as possible, the mutilation of the leaves. The present is a suitable time to attend to the cutting or trimming of dwarf coniferous trees and ornamental shrubs of various sorts, in which it is necessary to preserve a certain amount of uniformity as regards shape and size. Among plants well suited for this purpose are the Sweet Bay, the Portugal Laurel, the Laurustinus, &c., trained in the form of standards or otherwise, together with various sorts of Cypresses and Junipers, and other plants of a drooping habit of growth; also the Irish Yew (Taxus fastigiata), generally trained in the form of pyramids, upon which are sometimes grafted the gold and silver-striped varieties of the common Yew, a union which produces a very striking effect, as do also trained specimens of the fine-foliaged Maple (Acer Negundo variegatum), which, although deciduous, produces, nevertheless, during the summer months a very pleasing contrast when associated with sombre or dark-foliaged plants.

Fruit.

Strawberries.—Old Strawberry beds that have become exhausted should be dug over as soon as the fruit is gathered. The best method is to cut them off with the spade just below the collar and bury them as the work goes on, opening a trench for the purpose sufficiently wide at the commencement. The old tops thus dug under will benefit the ground, especially if it be of a heavy character. There is no better crop to follow Strawberries, when dug up at this time of the year, than Turnips, which should be sown as soon as rain falls after the ground is prepared.

Pears and Plums on walls should have their summer shoots removed as soon as they have ceased to grow, in order to give the tree a better opportunity to form fruit-buds for the ensuing year, and to expose them to the ripening influence of sun and air; but if such shoots be removed too soon, *i.e.*, whilst there is a considerable flow of sap in the trees, more harm than good will be done, as the trees will start again into growth. The usual way is to break off the breast-wood (for that is the term usually applied to these summer shoots) with the thumb laid across the blade of the pruning-knife, or a stout pair of ordinary nippers may be used for the purpose, severing the shoots at about ½ in. or ¾ in. above the point from which they spring.

Vegetables.

Sowing Cabbages.—In sowing Cabbage seed during the present month for the early spring supply, a difference of ten days has an important influence upon the time when the crop will be ready, and also affects the varieties grown. In the northern parts of the kingdom, where hardy sorts, such as the Enfield Market, stand the winter best, the seeds of these should be sown as soon as the 20th of the present month is passed; delay beyond this will cause the crop to be fit for use later in the spring. If sown sooner many of the plants will run to seed instead of hearting at the proper time. Where early varieties, such as the York, are grown, they must not be sown until eight or ten days later, or the plants will bolt. In the southern parts of the kingdom Cabbages should be sown a week later than the above dates, the later kinds being put in first and the earliest last. Where these directions are followed the disappointment of seeding instead of hearting will not be experienced. Select an open situation where the plants, from the time they are up, will get plenty of light and air, for the drawn and weakly plants sown near trees or high walls are not calculated to stand a severe winter.

Celery and Scarlet Runners.—Where the seeds of Celery were sown early, and the plants prepared with a view to obtaining an early supply, they will now be growing fast. Where the ground was well enriched there will not have been any necessity for watering; but where there has been a deficiency of manure, weekly applications of manure water will be required. Should Celery become at all affected with green fly, to which it is very subject if grown near anything else that is troubled with the insect, its presence will be indicated by the leaves curling up and an unhealthy, stunted appearance of the plants. So soon as any aphides are found give a good washing with soapy water from the wash-house, applying it with the syringe. To be effectual it must reach every part of the plants above ground, for, even upon such portions of the leaves as harbour no living insects, it is more than likely that there are eggs which will quickly come to life. Should they not be killed by one dressing, give a second within a few days. Scarlet Runners grown without sticks should have their shoots repeatedly nipped out as they push up.

GLASSHOUSES AND FRAMES.

Campanula calycanthema. — How rarely one sees this charming plant receive the attention it merits. I think it is not generally known how useful both the purple and white kinds are for pot culture, and with how little attention they may be grown to produce a most pleasing effect in the greenhouse throughout the months of April, May, and June if sown now or any time next month in pans, pricked out when large enough to handle, and in due course potted, increasing the size of pot each time they are potted, finally into 8½-in. pots, in which size they will make fine bushy plants in April; after the last shift stand them by in a cold frame, then let them remain until the month of February, when you may introduce them as required into a warm house; they will soon start into growth, when a little manure water will greatly assist them. I generally remove them out of the warm house into a cold one a short time before they open their flowers. When there is a great demand for large pieces of cut flowers for indoor decoration it is a most useful plant to grow. I frequently cut off the whole plant to the surface of the pot in one piece from 3 ft. to 4 ft. high, thus destroying the plant at once, but this one can do without incurring any serious loss or sacrifice. There is also a very old favourite plant which I have

applied to pot cultivation with equally satisfactory results as the Campanula, viz., the Corn Marigold (Chrysanthemum segetum); sown in September and treated as the above three plants in a 8½-in. pot, it will flower in March, and following months up to July. I have had large pots full of it in flower throughout spring this season. It is a common, valueless plant, and looked upon by some people as a mere weed; nevertheless, it is a very useful one when grown to flower in early spring.—G. B.

Lobelia in the Greenhouse.—Having an over-supply of Lobelia (Crystal Palace Gem), it occurred to me how well some small pots of it would look in the greenhouse interspersed amongst the other flowers; so I accordingly filled several 4-in. pots with nice clumps just coming into bloom, and now the result is that every one is delighted with the pretty effect the bright blue has in contrast with the various shades of crimson and yellow so abundant at present, and the scarcity of blue just now makes the Lobelia quite invaluable for inside as well as outside decoration.—W. A. G.

An Easy Way of Raising Tuberous Begonias.—Some persons find it so difficult to grow these beautiful plants from seed, that a simple plan I found to succeed admirably will no doubt prove useful to such. Last April I sowed a 1s. packet of seed in a pan of loam and silver sand and put it in a hotbed; but, seeing that the seed failed in coming up, I placed it under a glass in a warm corner of the greenhouse, and about three weeks after the young plants began to appear, and now we have several dozen of strong little Begonias ready for potting. This proves that these flowers can be raised without any bottom heat whatever, which is very important to know.—W. A. G.

Martynias and Campanulas.—I would advise amateurs to grow in a greenhouse Martynias. I had a threepenny packet, and they are splendid, easily cultivated, sweet-scented, and, in my opinion, as handsome as Gloxinias, and not requiring extra heat. Any one trying to grow them will be well repaid by the bloom. I would also mention Campanula calycanthema (white); mine are now in bloom lovely from seeds sown last summer.—MIGNONETTE.

Crassula coccinea or Kalosanthes.—This is an old greenhouse favourite, much thought of in former days, when gardeners used to grow specimens of it several feet through, each shoot being furnished at its summit with a broad truss of waxy-scarlet flowers, showy and sweet-scented. The plant also grows out-of-doors freely in summer, and when in flower is most brilliant and effective. This plant is known now-a-days as Kalosanthes. To flower it well it requires to be grown in hot, dry quarters. Cuttings, which strike very easily, should be made from the young shoots which have not flowered in August or early in September. Make the cuttings about 3 in. long; do not stop them, but divest them of a few of their bottom leaves, and pot each singly and firmly in a 3-in. pot, using a light compost of sand, leaf-mould, loam, and pounded bricks or crocks. They will soon root if placed near the glass in a warm pit, or an intermediate house shelf, if they are not damped too much at top or bottom. When rooted remove them to a cool, dry greenhouse for the winter, and give scarcely any water till spring; the object at this time is simply to keep them at rest. About the beginning of March the plants may be potted in 8-in. or 9-in. pots, which is a suitable size for plants intended to have six or seven shoots. A little heavier compost should be used for this, the final potting, and with it plenty of broken crocks or bricks, taking care also to drain the pots thoroughly. After potting, the plants should have a growing temperature near the light. A warm greenhouse or pit will do, but do not give too much water at any time. At this stage some of the plants will break up into a number of shoots at the top, and the others will keep to a single shoot only. The former should be thinned out to six or eight shoots, and the latter pinched at the top to make them break; the young shoots secured in this way will also bear flowers. By May the plants will be growing fast, and at this time they may, in warm localities, be plunged out-of-doors in a warm corner. In front of a hothouse is a good place for them, and it is a common practice to plunge them in sand, which gets hot with the sun; otherwise they need not be plunged at all, but simply set on a hard surface. In cold localities it is better to grow the plants under glass all summer with plenty of air and sun. Whichever plan is adopted, let the plants from this time grow uninterruptedly, and before cold weather sets in take them into any house where the temperature is genial and dry. Here they will show flower, if the trusses are not already in an advanced state, and the season of flowering may be prolonged by keeping the plants in cool houses. If the plants are intended for planting out, they must simply be wintered in a cool house and not permitted to flower, and planted out the following season, where they will be certain to flower and make a bright display.—J.

Tabernæmontana camassa.—Growers of flowers for market should cultivate a house of this plant alone. It is a newly-introduced evergreen stove shrub of a neat, compact, dwarf habit, with glossy bright Laurel-like leaves and racemes of double white flowers of Gardenia-like outline and fragrance, which are produced on the point of every shoot. From the Gardenia it differs in its easier growth, and in requiring a much less stimulating atmosphere to produce its bloom; the usual temperature of a hothouse with less humidity will produce blooms more freely and longer in succession. The petals of the flowers are lighter and more elegantly arranged than the Gardenia and not quite so large; small plants in 3-in. pots will produce flowers freely.—J. S.

A Fine-leaved Hothouse Plant (Dieffenbachia baraquiniana). — This Dieffenbachia, an illustration of which is given on the next page, is the best species of an easily-grown, handsome genus of hothouse plants. It is of moderate stature, and associates well with larger fine-leaved plants, or it may be intermixed with flowering plants. It is a free grower, and is not over particular as to the material in which it is grown. Either peat or loam, or a mixture of both, will suit it, to which add a liberal admixture of clean sand, with a little thoroughly rotten manure. Use plenty of drainage. The plant will stand a liberal shift, say from a 6-in. pot to a 10-in. or 12-in. one. It will grow well in a moist warm temperature, and it must never, even when comparatively at rest in winter, be subjected to a temperature lower than 50° or 55° at night. It is a gross feeder, and will grow all the better if supplied occasionally with manure water; it is, however, best as a rule not to apply liquid manure to quick-growing, succulent, variegated plants, as most of them do not come so finely coloured if grown too vigorously. This Dieffenbachia is not much troubled with the attacks of insects, but should they appear they are easily kept in check by an occasional application of the syringe. It strikes freely from cuttings made of short pieces of the stem inserted in sand, and kept a little close until they have struck root. It likes a little shade during the growing season, as its leaves are too soft to withstand the sun's rays when at all powerful. The beauty of its leaves makes it a desirable plant for room decoration, but it must not be kept too long indoors at a time, or it will fall into ill-health.

NATIONAL ROSE SOCIETY.

THE exhibition of this society, which was held at the Crystal Palace on July 3, was better than many expected on account of the bad season for Roses which we have had, the classes being fairly well filled and the quality of the blooms of the usual high standard of excellence. The amateurs' exhibits were, on the whole, superior to those shown by nurserymen, and especially those in the contending stands for the challenge cup, some of which were remarkable examples of high class culture. The small collections shown by amateurs were particularly good, while the growers about London and others, whose nurseries are in cold soils, could not show such fine blooms as they do in some seasons; and the absence of many leading growers in the trade was a conspicuous feature. The only miscellaneous exhibit was some bright collections of cut blooms of Pelargoniums, backed by a fine row of Canterbury Bells in various shades of colour, the whole forming an attractive display, which tended greatly to relieve the monotony of the long lines of Rose boxes. Some of the finest blooms in the amateurs' winning collections were Annie Laxton, Dr. Andry, Sultan of Zanzibar, Madame Frères, A. K. Williams, Capt. Christy, Madame Charles Wood, La Havre, Elie Morel, Princess Beatrice, Alfred Colomb, Duchesse de Vallombrosa, Abel Carrière, Marie Van Houtte, Fisher Holmes, Exposition de Brie, Hippolyte Jamain, Beauty of Waltham, François Michelon, Sir Garnet Wolseley, Henri Ledechaux, Mons. Noman, Duke of Wellington, Madame Marie Finger, Comtesse d'Oxford, Marie Baumann, Madame Lacharme, Marguerite de St. Amand, Madame Furtado, Lord Macaulay, Souvenir d'Elise Vardon, Camille Bernardin, La France, Xavier Olibo, Baron Brouste, Magna Charta, Charles Lefebvre, J. S. Mills, Auguste Rigotard, Mons. E. Y. Teas, Duke of Edinburgh, Marguerite Brassac, Ferdinand de Lesseps, Catherine Mermet, T. Mills, Madame Victor Verdier, Edouard Morren, Jean Luizet, Mdlle. Marie Rady, Pierre Notting, and Madame Hippolyte Jamain.

ALEXANDRA PALACE ROSE SHOW.

JULY 10.

THIS was quite a novelty in the way of Rose shows, the competitive exhibits being supplemented by an immense mass of Roses sent by Messrs. William Paul & Son, of Waltham Cross, who has undertaken to keep up the display until the 17th. The show was arranged in the centre transept, which had been made exceptionally tasteful. The collateral display made by Messrs. Paul & Son comprised an extensive arrangement which filled back and front, two elevated stages erected the whole length of the centre transept on each side. Mr. Cannell, Swanley, showed eighty trusses of both double and single zonal Pelargoniums, making in this respect a fine display. Alongside were thirty-two varieties of Verbenas, showing a wonderful variety of colour and an advance of size by comparison with many older examples. Among some of the most remarkable blooms of Roses shown may be mentioned Etienne Levet, Marie Baumann, Baroness Rothschild, and La France. A detailed list of awards will be found in our advertisement columns.

An Unexpected Crop of Mushrooms.—In the summer of 1879 my gardener made a bed for Mushrooms in a covered frame, but nothing whatever came in it. In May of the present year he prepared a bed for Tomatoes in the open air close to the garden wall, having a south aspect. On this with more manure he put the contents of the old unproductive Mushroom bed. The result is a continuous and abundant crop of remarkably fine Mushrooms. More of the same bedding was put on other beds, but no Mushrooms yet, July 8.—A.

FRUIT.

Strawberry Culture.—The letter of "R. E." in GARDENING, June 26, so fully gives directions for Strawberry culture, that I have little to say. Of course runners should be taken from fruiting plants and pegged into pots, though I have found pegging into the ground answer fairly well. I use hairpins as the cheapest of peggers. The pots should be sunk in the ground and watered when the plants are taken from the parents. I put all the pots together in a very shady spot. As they are easily watered I always plant the runners in a triangle, 4 in. apart; when showing bloom next spring I go over all, and if I see any barren ones, pull up. It is an excellent plan to tie the flower-stalks together with a thick soft bit of twine or bast, putting the string through the ring of a croquet spike, so as to keep up the string; if the leaves can be kept down and the fruit fully exposed to the sun, they are much sweeter and ripen better. And now I would ask information as to keeping the fruit clean, and at the same time prevent slugs from eating the fruit. This year I have tried Cocoa-nut fibre, but the rain washes it away. Last year I tried tan, the carriage of a cartload costing 8s., and the Strawberries were clean, but still the slugs eat them. I use crinolines, two dozen; they are best of all, but 500 of them at 7d. each would be nearly £15—too expensive. I believe half circles of earthenware are made, and they are very useful to keep the

fruit clean, but I fear not to keep off slugs. I have thrown lime over the plants, but the rain soon washes it off. As to traps of bran or brewer's grains, I have tried both, and never caught a slug. I this year trapped a number of large slugs with Cabbage leaves, but the Strawberry slug is, I think, a different kind to the others—a small grey slug. I think the best plan is to tie up all the fruit stalks, and let them have sun, and give water; but this must be carefully done, for I got a boy to help, and all were tied so loosely, that the fruit by their weight rested on the ground. Mulching keeps clean, but is of no use against slugs.—OLD INDIAN.

Manure Water for Strawberries.—Never, I think, has the show of Strawberry blossoms been finer than it was this year, but in many cases the fruit has not been proportionate. When the blossoms of the earlier sorts had fallen, I noticed that the stalks continued upright, and the calyx spreading star-like instead of folding over the young fruit; I instantly took the alarm, knowing the fruit could not be setting or swelling. I accordingly poured pails full of liquid manure between the rows, of course taking care that none went over the plants; a good deal of the manure went through the spout of the watering-pot; every alternate night I washed in this with clear water, and then the rain came, and I have a very large crop of deliciously flavoured fruit; have quite beaten all my neighbours, who simply used clear water, although all have certainly four times my number of plants. I think the management of Strawberries must be varied according to soil. In our sand of Redhill I find it the best plan to keep the ground between the rows as hard as possible, and if I mulch with manure at all I do it in the spring. My plants have been in the same place some six years. Now and then I destroy a row of old plants and put in the runners which have rooted from them. I simply plant them, and do not touch or manure them in any way. The success of my plan is the wonder of my neighbours, although the gardeners, who come to assist me very occasionally, from time to time shake their heads and protest—"they do not hold with them doings."—MARK.

Potting Strawberries.—An eminent fruit grower has stated that these should be potted as firmly "as the fingers and thumbs can make them." In the open quarter Strawberries like a deep, open soil, and they, too, will send their roots down to a great depth; but with pot plants for forcing it is different. The less-sized pots they can be crammed into consistently the better. The object should be to get the pots well packed with roots before winter; 4½-in. and 5-in. pots, and for the most vigorous growers 6-in. ones, are as large as should ever be used. The last size is rarely employed; the 5-in. suits almost all kinds, and if the plants be potted tolerably hard, it is as much as they can do to fill the pots before October, after which time it is preferable that the plants should mature rather than prolong their growth. In the case of Strawberries, however, it is possible to make the soil too hard, as has been proved. Under the roots, next to the drainage, the soil may be pressed hard enough, but in filling in round the plants it need not be rammed quite so firm.

Training Fruit Trees.—The illustration on the opposite page represents a form of training Pear trees much employed in France. It is an excellent way, but for covering the wall quickly we prefer the upright style of tree with two main branches in the shape of a U. This form of training of course takes more trees in a given space than the one shown in our illustration, and therefore many may prefer the latter way.

A fine-leaved Hothouse Plant (Dieffenbachia baraquiniana). (See preceding page.)

ANSWERS TO QUERIES.

2459.—**Hedges for a Garden.**—Privet makes a good hedge quickly, and will answer for divisional lines. White Thorn is better where sheep or stock have access, or a mixture of Thorn and Privet makes a good fence, especially for sandy situations, as the Thorn gives strength to the Privet to enable it to resist the force of the wind. There is an objection to Privet: its roots rob the land more than most plants. The Yew tree is a good hedge plant, and grows quickly; so also is the Arbor-vitæ and the Holly. The Privet, however, is the fastest grower and cheapest.—E.

2447.—**Growing Tobacco.**—I do not think that, legally, Tobacco can be grown at all in this country, although, of course, the Inland Revenue officials never trouble about a few plants grown for private use or experiment. The seed should be sown in March on a slight hotbed and be thinned out to 2 in. apart, or it may, if desired, be sown in pots or pans and pricked off when large enough. The young plants should be hardened off in the same way as ordinary bedding plants are, and be planted out about the middle of May, 2 ft. apart, on good land. When the plants show flower pinch out the points to take off the flowers, as they take some of the substance from the leaves. When full grown and the leaves are beginning to change colour cut the plants off at the base, and hang them up in an open shed to ripen off. When this is done gather the leaves and place them in a heap to ferment. If there is only a small quantity place them in a warm house, such as a Mushroom house, for two or three days. After the fermentation has proceeded the time I have mentioned let them dry again, and it may be necessary to ferment them again in order to give the Tobacco a mellow flavour. Perhaps for merely fumigating purposes once fermenting will be sufficient. It should be thoroughly dried and packed away in a dry place. The Virginian Tobacco (Nicotiana tabacum) is the kind commonly grown, but Nicotiana rustica is hardier and dwarfer, and would suit our climate better.—E. H.

2461.—**Ants in Lawns.**—Scatter guano in the ants' runs and about their nests. Water with a mixture of paraffin and water, a wineglassful of the former to a gallon of the latter. If any should remain in the autumn, take up the turf, dig out the rest, water the place with the paraffin and water, and lay down the turf again. They do not like to be disturbed; digging up their nests generally banishes them.—E. H.

2450.—**Slugs, Snails, and Wireworms.**—Paraffin of a less strength than one gill to the gallon will kill all insect life. A wineglassful to two gallons will be ample. I should not recommend salt now, as if given strong enough to kill snails it might kill the crop also. The cheapest and simplest plan is to obtain some brewer's grains and lay about in small heaps, visiting the place after dark with a light and destroying the enemy. Scattering a few sifted coal-ashes round any plants generally saves them, as the snails cannot travel over the jagged edges; they stick on their slimy bodies. A very thin sprinkling suffices.—H.

2449.—**Insects on White Thorn Hedges.**—The best remedy is the natural one, viz., to encourage the birds to build their nests in it and feed their young with the insects. An unlimited supply of soap-suds applied forcibly through a garden engine will be useful, and a simple remedy, and one easily applied, would be to dust it over with equal quantities of fresh lime and soot mixed.

2451.—**The Currant Caterpillar.**—Looking over the bushes in May and picking off the leaves on which the eggs are laid will probably be the best and cheapest plan to adopt another year. Take a peck of fresh soot, tie it up in a cloth, and sink it in a tub containing thirty gallons of water. Stir it occasionally, and at the end of three days drop in a lump of lime (about 2 lb.) to clarify it. Syringe the Currant trees in the evening with the liquid.—E. H.

2445.—**To make Skeleton Leaves.**—Mix a tablespoonful of chloride of lime in a liquid state with a quart of pure spring water, soak the leaves or seed vessels of plants in the mixture for about four hours, then take them out and well wash them in a large basin of clean water; after this they should be left to dry with free exposure to light and air. Some of the larger species of forest leaves, or such as have strong ribs, will require to be left rather more than four hours in the liquid.—JANE.

2448.—**Treatment of Grevillea robusta.**—There are few plants more easy to keep in good condition in a room than Grevillea robusta. It needs only to be supplied with water when necessary, and to have the foliage well washed once a week, and it will retain its beauty for years without even needing to be repotted. The best place for it is a light, well-ventilated apartment, which is kept quite cool, but from which frost is excluded during the winter. It will, however, thrive in a warm room where gas is burnt, but when thus placed take it out once or twice a week and well wash the leaves. Some of the lower leaves are sure to drop at this time; these may be removed, as they become unsightly; they will not be missed if the plant is otherwise growing freely. Nex

April the plant may, if so desired, be shifted into the next-sized pot, using a compost of half peat and loam. When the nights are warm place it in the open air, sprinkling it with clear water. Such treatment will have a most refreshing effect, and will endow any foliage plant with sufficient vigour to pass the winter in good condition. All plants intended to be kept in rooms during the winter should be as much exposed to the full air during the summer and early autumn months as their respective natures will allow of.—J. CORNHILL.

2456.—**Propagating Wistarias.**—These are propagated by means of layers. Strong young shoots of the current season's growth are chosen for the purpose, every other joint being cut about half through with a sharp knife, and fixed into the soil by means of a stout peg. During the summer roots will be emitted, and in the autumn the plants may be taken off and planted out. Layering may be performed either at the fall of the leaf or during March. As to soil the Wistaria is by no means particular, preferring, however, like most other outdoor climbers, a good sound loam. Where the natural staple is poor, gravelly, or parching, it should be taken out some 2 ft. in depth, to be filled up with a prepared compost of loam and a little good manure, road scrapings, leaf-mould, or any good material which may be at hand may be added to it well incorporated with the natural soil. Climbers of all kinds enjoy a free extended root-run in congenial soil, and seldom give a faithful idea of their worth and beauty unless thus circumstanced. The greater the pains taken to prepare the soil for the reception of the roots, the more satisfactory will progress be, not only during the first few seasons, but also in after years.—J. C. B.

2399.—**Plants for Photographic Studio.**—We cannot think of anything more suitable for the purpose than Euonymus japonicus. At the same time we should inform you that it is a matter of considerable difficulty to preserve in health hardy evergreens of any kind in a close apartment. During the summer months they require full exposure. The only way to obtain fair success is to give abundance of air at all times, occasionally taking the plant out and thoroughly washing the foliage.—B.

2442.—**Cultivating Indian Plants.**—The seedlings should be potted off when large enough to handle into small pots, in a well-sanded compost of fibrous peat. Keep them growing freely in a close warm house, shading from hot sun, but admitting as much light as possible. The Asparagus and Acacia should, towards the close of the summer, be placed in a somewhat cool, airy situation, and may be wintered in a temperature of 50° to 55°. Bixa orellana, when well established, does not demand a high temperature, and requires a somewhat free admission of air during the summer months. Without knowing what species of Clitonia and Bauhinia are referred to, the exact temperature and treatment cannot be indicated. A minimum temperature of 50° by night and 55° by day will, however, suffice to maintain the generality of them in health. During the summer months they prefer a position near the glass, where they get a portion of the sun's rays without being subjected to its full force. At the same time a moist, growing atmosphere must be at all times maintained around them, and the foliage should be occasionally sponged. In potting, the most perfect drainage should be given, and plenty of river sand should be used in the compost.—J. C.

2455.—**Raising Begonias from Seed.**—The great point in sowing Begonia seed, or, indeed, any seed, is to so place it when sown that it is not in any way affected by atmospheric fluctuations. If the soil becomes dry there is a great chance of the seed suffering at a critical moment, and unless watering is conducted with extreme care, there is, in the case of such minute seeds as those of the plant in question, considerable danger of their perishing from excess of moisture. Having filled the pot with proper soil, water it so that the whole body of it becomes thoroughly moistened, allow it to stand until superfluous moisture has drained away, and then scatter the seed thinly upon an even surface, and cover very thinly with fine soil or silver sand. Place the pot in a moist, shady, close situation, cover the pot with a piece of glass, placing thereon a piece of paper, keeping the seed quite dark until germination takes place. In this manner there will be no need to water; the soil should remain quite moist until the seedlings are above ground. If these instructions are carried out and the seed is good, almost every grain will germinate. I am, however, of opinion that the seed of Tuberous Begonias loses its germinative power much sooner than is the case with most other seeds; it is therefore highly imperative that it should be procured quite fresh. Buy your seed of some grower who makes a speciality of this plant, and who grows the seed he sells.—C., *Byfleet*.

—— Fill a 6-in. pot to within ½ in. of the rim with a mixture of good fibrous loam, leaf-mould, and sand. Sow the seed equally, cover with ¼ in. of compost, place a piece of glass over the pot, and then plunge in a gentle hot-bed. In six weeks it will be up. Seed sown now will make fine plants next spring for either exhibition or decorative purposes.—J. C. B.

2453.—**Lily of the Valley not Flowering.**—The Lily of the Valley should thrive and flower very well in the situation mentioned. It is a plant which grows naturally in moist, sheltered, and partially shaded places; at the same time, when large highly-developed crowns for forcing are desired, it is better to grow in more full exposure, and trust to rich deep soil and copious waterings to supply the necessary conditions. Where, however, flowers of average quality only are required, they may be obtained in almost any obscure corner of the garden.—C.

2454.—**Fuchsias for Greenhouses.**—Avalanche, Rose of Castile, Miss Lucy Finnis, Tryme-O, Earl of Beaconsfield, and Mrs. Marshall. These are six of the best Fuchsias that an amateur can grow, being distinct, of excellent habit, and profuse flowerers. Mrs. Marshall is an excellent forcing kind, being largely grown for Covent Garden Market. Rose of Castile may be had in bloom almost up till Christmas. Avalanche is the most free flowering dark double that I am acquainted with, and Earl of Beaconsfield is so distinct, that no collection should be without it. If any more were needed I would add Boliviana, an interesting and distinct kind, with handsome foliage and of graceful habit.—J. C.

2444.—**Irises from Morocco.**—The Iris in question is probably I. alata, a winter flowering species, and worthy of pot culture. We would pot them at once, keeping them in the open air until the middle of October, and then placing them under cover. They may not flower well the first year, owing to the removal, but will in all probability give a good show the following year.—B.

2457.—**Elder Trees from Cuttings.**—The insect might be one of the Snake Millipedes, and if so, it might have eaten the young succulent roots of the Elder cuttings. Lime, soot, and salt—the latter in moderate quantities—are beneficial applications for land infested with insects.—E. H.

2451.—**Gooseberry Caterpillars.**—If the Gooseberry or Currant bushes are standards, or can be made so, procure a thin rope in which there is a strand of horse-hair; tie it round the stems; it acts as a *chevaux de frise*—no caterpillar will pass it. I used the rope of an old casting-net.—M. P. D.

Although the following questions are answered by the Editor, he will be obliged to any of our readers who may think well to answer them again.

2534.—**Strawberry Runners.**—*H. H. H.*—To obtain Strawberry plants, peg down those runners which have plump crowns and plenty of healthy foliage. They are best pegged into 3 in. pots, filled with good soil. When you have chosen what runners you require, the others may be cut off; also all runners proceeding from those pegged into the pots.

2535.—**The Screw Pine in Windows.**—*W. G.*—The reason the young leaves are twisted is probably because the plant gets often moved, and the leaves in struggling for the light get twisted round. The plant wants to be in a glasshouse with plenty of heat and moisture in order to succeed well.

2536.—**Treatment of Yuccas.**—*Eliza.*—Very small plants are best grown in pots, so that they can be placed in a frame or greenhouse during winter. Very small plants are often a long time before they make rapid growth.

2537.—**Foxgloves.**—*A. B.*—These are perennials, and should flower every year. A few of the species are only biennials.

2538.—**Vegetables on Peat Land.**—I have some peat land that I am getting into cultivation. It has been trenched 2 ft. deep and the peat burnt. What vegetables may I grow? and what would be the best manure for such land?—D. J. T. [If you manure it heavily with good rotten farmyard manure now, well incorporating the manure with the soil, you might next year be able to grow Potatoes, Lettuces, French Beans and Scarlet Runners, Beetroot, and even Carrots, but you cannot hope to grow well such crops as Broccoli, Cabbage, &c., that require stiff land, until you can give the ground a good dressing of clay, marl, or stiff loam.]

Pear tree as trained in French gardens.

2539.—**Striking Rose Cuttings.**—*Roby.*—August is the best time to take cuttings. Shoots of the current year's wood with a heel attached are the best to take. Plant them firmly in sandy soil in a shady situation. See illustrated article on this subject in GARDENING, Aug. 9 last.

2540.—**Propagating Seakale.**—*E. B.*—Lift some of the old plants in January, and trim off the thongs, leaving only the straight stem. Then put these old plants into a box of soil in a cellar or similar place where it is dark, and you will get some early Seakale. Cut the thongs into 4-in. lengths, and plant them close together in a bed of light soil, covering them over 2 in. or 3 in. In March or early in April they will have commenced to grow, when they should be taken up and have all the buds rubbed off, except the strongest on the top of the root, and be planted in threes triangular fashion, putting them about 5 in. apart, each set of plants being 2 ft. apart.

2541.—**Budding Roses.**—*W. A. V. S.*—The Roses you mention, viz., La France, Duchess of Edinburgh, Jules Margottin, Madame Victor Verdier, and Mdlle. Annie Wood, are all good kinds, and will succeed when budded on Brier stocks. They also succeed as dwarfs either on the Manetti, or on their own roots. We should advise you to strike cuttings in autumn, and thus obtain plants on their own roots. The Cabbage Rose will do well budded on the Brier.

2542.—**Sweet Williams.**—*W. S.*—Seed of these may be sown now in rather rich soil in a shady part of the garden. When large enough, put out the plants where they are to bloom. The wet weather would probably be the cause of your plants rotting off, and your soil may be badly drained. Tall-growing kinds require some support when flowering, or rough weather will soon break them down. Get Hunt's or Dean's strain.

2543.—**Manetti Stock.**—*M. G.*—This is a strong-growing Italian Brier. You could doubtless obtain plants of it on which to bud Roses from any extensive Rose grower.

2544.—**Vegetables in Shallow Soil.**—*W. T. K.*—The reason the vegetables run to seed is because the good soil is so shallow, and they will not root in cold clay. Next winter trench the ground all over, bringing up a few inches of the subsoil, and incorporate it well with the top soil; also put into the bottom of each trench a good lot of rotten manure and some coal ashes, and well dig it into the clay. This should be repeated each year, and in time you will get a good depth of rich soil.

2545.—**Cucumbers Failing.**—*Amateur.*—Cucumbers that have been fruiting in a frame since April last probably need a little renovating. Give them a top-dressing of good rich soil, pick off all blossoms and fruit, and stop the shoots. Remove all weakly growths and peg the strong ones down. If there is any green fly on them, fumigate with tobacco for several evenings in succession. Keep a moist temperature, and doubtless the plants will recover their strength.

2546.—**Apple Trees as a Screen.**—*Ailenroc.*—Apple trees trained as espaliers would form a good screen in summer; in winter, of course, they would be bare. Cox's Pomona is an excellent sort for espaliers. Plant the trees 4 ft. apart, and train the shoots upwards, not horizontally. They will then soon cover the trellis. A strong wooden trellis painted would be better than a wire one.

2547.—**Asparagus Planting.**—*G. T.*—It is much better to plant young plants than old ones, as the latter seldom succeed after removal. Get two-year-old plants in spring.

2548.—**Cyclamens after Flowering.**—Is it necessary to keep the earth around Cyclamen corms moist after they have quite done flowering for the season?—J. H. M. [Give just enough water to keep the leaves from flagging.]

2549.—**Treatment of Maiden-hair Ferns.**—I have a very fine Maiden-hair Fern in a pot; what should be the treatment of it before winter?—W. V. [Keep it in a light but sunless place, and give it plenty of water. In winter less water will be needed.]

2550.—**Plants in Lumber Room and Attic.**—*Stag.*—In such places you can winter Fuchsias, Geraniums, and similar plants, but you could only grow plants in the windows.

2551.—**Pyrus japonica.**—What is the proper management of this on a wall? It covers a space of about 3 yds. and makes long shoots every year. I cut it in very close last autumn, and it has scarcely flowered this year. It is again covered with young wood about 1½ ft. to 2 ft. in length.—W. D. [Let the tree remain as it is, only nailing in the leading shoots.]

2552.—**Summer Pruning Fruit Trees.**—I have some thirty Apple, Pear, and Plum trees on a wall which I have trained as upright cordons. Having been absent from home since the beginning of May, I find they have made by this time a rampant growth, in some cases of 3 ft.—W. D. [Cut them back to three or four eyes. You need not remove them all at once; go over them two or three times.]

2553.—**Sowing Pansy Seed.**—*H. H. H.*—Pansy seed sown now will produce plants which will flower next spring.

2554.—**Forcing Asparagus.**—*H. H. C.*—If you obtain good plants from any nurseryman early in December, and plant them in a frame on a good hot-bed, you may easily get "Grass" fit to cut in January.

2555.—**Brussels Sprouts among Potatoes.**—This year I planted my Brussels Sprouts between rows of Potatoes, the latter being planted the usual distance apart from row to row to allow the Sprouts proper air. Owing to the season the tops of the Potatoes have grown beyond all bounds, and are choking the Sprouts, and will in time spoil them. Would you advise me to cut the Potato tops down to give proper air and light to the Sprouts? Such a course I have seen recommended when disease is attacking Potatoes.—AMATEUR. [We should not advise you to cut the tops off the Potatoes; rather go to the trouble of staking the Potato haulm up a little. This may be done by driving stout stakes 3 ft. or 4 ft. apart along each side of the row, and straining stout strings from stake to stake.]

2556.—**Celery Without Trenches.**—Will this succeed grown on the level ground? if so, what is the proper course of earthing up, &c.?—IGNORAMUS. [Celery will succeed well when planted on the level ground. When it requires earthing put a paper band round each head and put a drain pipe over them, filling up with fine dry soil or sand. If one drain-pipe is not sufficient, another may be placed on the top of it, driving a stout stake by the side to which to tie the pipes to.]

2557.—**Material on which to Stand Plants.**—What is best for material to put on the stage of a greenhouse for pots of Ferns and flowering plants to stand on?—J. A. [Broken sea shells or gravel, out of which has been taken the finest and coarsest portions. It should be well washed before use.]

2558.—**Pansies and Violas.**—What is the difference between "white selfs" and white grounds, and "yellow selfs" and yellow grounds?—OLD SUBSCRIBER. [If you had a black coat with white spots on it, the ground colour would be black; if a black coat without spots, it would be a black "self."]

2559.—**Writing on Labels.**—Which end of a label is it proper to commence to write from, the top or pointed end?—W. BENNETT. [In writing labels the writer should always begin at the top and write towards the pointed end.]

2560.—**Rose Suckers.**—About two months ago I planted some Rose bushes, and all the leaf-buds that were on them died off. They are now making fresh growth, mostly from the bottom part of the plants. I can tell which are suckers and which are not, as I suppose all suckers should be taken away.—SOUTH HACKNEY. [There is a great difference between the growth and leaves of the suckers and those of the Roses. Examine the plants and find out where they were budded; all below the part where the bud was inserted should be removed.]

2446.—**Flower Boxes** faced with fancy tiles require slips of wood rabbetted or grooved and screwed on top and bottom edges, mitred at the corners; rounding the top edges of the slips or bedding tiles in plaster is optional.

2561.—**Seedling Carnations to Flower in Winter.**—Pot them into 5-in. pots, and plunge them in ashes out-of-doors in an open sunny situation. Give them plenty of water, and house them when frost appears. Introduce into a warm house when the flower-buds show themselves.

2562.—**Sportive Foxgloves.**—*Mrs. Wm. S.*—The cultivated Foxgloves frequently produce abortive flowers. The flower you send is a combination of several buds which have developed into one cup-shaped blossom.

2563.—**Vines Scorching.**—*C. R. H.*—Young Vines exposed to the full sun are very liable to be scorched at this season when one day is all cloudy and the next all sunshine. Shade the young leaves slightly with thin canvas or a little whitewash rubbed over the glass, and give air early in the morning.

2564.—**Roses not Flowering.**—*Siward.*—Some kinds of climbing Roses take longer to reach a flowering stage than others. They will doubtless flower all right next year.

2565.—**Propagating Laurels and Laurustinus.**—*C. J. F.*—Take cuttings of the current year's growth in September or October, and plant them in firm sandy soil, or they will strike in spring when growth is about to commence. If taken off with a heel, *i.e.*, a piece of the old wood attached, the cuttings are more likely to strike.

3566.—**Tuberous Begonias Failing.**—*A Learner.*—The fact of your keeping the plants in a shady place, and then suddenly exposing both leaves and roots to the full blaze of the sun, will account for the leaves drooping. They should have been inured to the sun gradually.

2567.—**Lilium auratum after Flowering.**—*Cyclamen.*—When the stems have died down repot the bulbs in the same sized pots, removing most of the soil from their roots. Use turfy loam, plenty of silver sand, and some rotten manure or leaf-mould; withhold water until growth commences.

2568.—**Melons Damping off.**—*F. H.*—We cannot tell you why your Melons damp off without knowing under what conditions they are being grown. Probably it is for want of heat, or too little air, or both.

2569.—**Cyclamen not Flowering.**—*Cyclamen.*—Take the bulbs out of the pots, remove most of the soil, and repot in the same sized pot, using turfy soil and leaf-mould. Plunge the pots in a partially shaded situation; take indoors in autumn, and place them where they can get plenty of air.

The Best Winter Lettuce.—*Old Indian.*—The London Cos; All the Year Round is an excellent Cabbage Lettuce.

Twin Cucumbers.—*R. W. B.*—By no means uncommon.

QUERIES.

2570.—**Balsams for Show.**—I have strong healthy Balsams in 9-in. pots, which I intend to exhibit about the 1st of September. When should the last potting be made, so as to have them in full bloom by exhibition time? They are in an ordinary greenhouse, where they get plenty of light and air.—A GENERAL SUBSCRIBER.

2571.—**Window Plants.**—I am living close to the outskirts of a town where the air should be comparatively pure, yet my window plants loose all their leaves during the winter, consequently they cannot regain them in time for flowering properly. I keep them in a window facing due west, therefore they do not get any sun till late in the day. The flowers consist of Fuschias and Geraniums.—GEORGE WOOD.

2572.—**Forming a New Garden.**—Will any of the correspondents of GARDENING ILLUSTRATED kindly inform me how to go about forming a kitchen and fruit garden? I have purchased a couple of acres of land in Cheshire, and intend to lay out about half an acre in garden; the land is at present under Grass. The soil is a fair loam, about 1½ ft. deep, but with a clay subsoil.—NOVICE.

2573.—**Ants in Gardens.**—My garden is overrun with ants—some black, and others of a red colour. How can they be effectually destroyed and totally exterminated?—P. LL.

2574.—**Removing Moss from Stones.**—Can any reader tell me how to remove Lichens and weather stains from stonework?—JANE.

2575.—**Propagating Myrtles and Roses.**—I put in some cuttings of climbing Devoniensis about the middle of May in the way recommended by "Mark" (answer 1848), but all have failed. Will "Mark" kindly inform me at what time of the year he put in his Rose cuttings? how long they were in rooting? and, when that had taken place, whether they were put into pots or at once into the ground? Any information on raising Roses from cuttings will greatly oblige.—ELIZA.

2576.—**Copying Machine.**—In "Subscriber's" receipt for making a copying machine he does not mention what quantity of glue is to be dissolved in water with which to mix the other ingredients. Would he be kind enough to do this?—A TEACHABLE READER.

—— There appears to be a slight mistake in the receipt given in GARDENING ILLUSTRATED, July 3, and "Subscriber" would oblige by giving some further information. "Subscriber" says:—"Gelatine glue, 2½ oz.; water, 5 oz. Let the above soak together for twelve hours, then add glycerine, 5½ oz. (fluid); carbolic acid, minims x. Dissolve glue in water at a gentle heat in a jar in pan of water, then add the other ingredients." Must the glycerine and carbolic acid be mixed with the glue and water before the glue has been dissolved in the pan of hot water, or afterwards? and how long should the whole be kept in the pan of hot water? Am I correct in supposing that "minims x" means ten drops of carbolic acid?—C. H. A.

2577.—**Figs not Fruiting.**—I have a Fig tree in a greenhouse, and the soil is gravelly; it thrives well, but this year it bore no fruit. Perhaps some readers will kindly give some probable reason for it, and give instructions when to prune it and what shoots to dispense with?—J. B.

2578.—**Blight on Asters.**—My Asters are attacked by a kind of black fly; the effect on the plants is that of shrivelling the leaves, and it greatly retards their growth. Can any reader suggest a remedy?—JOHN E. CHEESE.

2579.—**Treatment of Auriculas.**—I have a number of seedling Auriculas ready for pricking out into pots Will some reader kindly explain their course of treatment? They are not the alpine variety. Will they bloom next spring?—JOHN E. CHEESE.

2580.—**Pansies for Show.**—Will some one suggest how Pansies should be arranged for exhibition, remembering that without plenty of moisture they soon fade—W. G. R.

2581.—**Heavy Strawberries.**—I have had fruit of James Veitch Strawberry this season which weighed 2½ oz. each. Is this an unusual weight for a Strawberry?—J. M. P.

2582.—**Unheated Glasshouses.**—I think of putting a glass roof, 3 ft. deep, against a garden wall, resting on iron brackets, leaving it open in front and at the sides, planting Chrysanthemums and Roses at the back, and in front Auriculas and Christmas Roses. Will some practical person say if this will improve these flowers and prolong their flowering? and if any other hardy herbaceous flowers would be the better for being planted under such a shelter, say Fuchsias? Would Tree Carnations stand the winter under such a roof, Malmaison, for instance? Ought I to have frames to cover in the sides with canvas stretched over, and leave only the front open? I shall be truly grateful for advice, and what would be the cheapest way to get the glass roof and fix it?—AILENROC.

2583.—**Apples and Pears for Town Gardens.**—Will any one give me the names of six good Apples and two Pears which will succeed in a town garden?—AILENROC.

2584.—**Disease in Cucumbers.**—I have lost three fine Cucumber plants from a disease which causes the stem to rot away just above the earth. Can any one tell me the cause and the remedy?—AVE.

2585.—**Mushrooms in Passages.**—Would Mushrooms grow in the passage to an ice well where all light is excluded? If so, would some reader kindly give me a few instructions as to the management of them?—G. B.

2586.—**Carnations and Picotees.**—Which are the best six sorts of each of above? If pipings of each be obtained now and struck, will they stand the winter?—IGNORAMUS.

2587.—**Roses for North Aspect.**—What six kinds of standard Roses would be best for planting in a northerly aspect on good mixed loamy soil in West Suffolk—good decided colours? and also those that come on in succession—some early and late preferred? When should they be planted?—IGNORAMUS.

2588.—**Plum Trees not Bearing.**—I have two Plum trees which I planted four years ago; they have grown about 12 ft. high against a wall facing south, are healthy and strong, but have not yet fruited or blossomed. Some of the branches are nailed to the wall, others grow straight out at right angles, with profusion of foliage. How and when must I prune them to induce fruiting? Does the fruit come on this or last year's wood?—HOLLOWAY.

2589.—**Fruit Falling from Trees.**—Perhaps some reader might be able to give some instruction how to improve Cherry and Plum trees which, after blooming well and setting their fruit, cast it off when it is about the size of Peas, leaving scarcely any on the trees. Mine have done so for the last seven years or more.—NOVICE.

2590.—**Roses not Blooming.**—I planted two Gloire de Dijon Roses two years ago last autumn; one has not yet produced a flower, the other has showed two this year. In a short space of time they threw shoots 2 ft. and more in length, with fine foliage. They are planted at the foot of a raised bed. My other Roses do well in the same position and soil. Will any one tell me how to get more bloom and less wood?—A CONSTANT READER.

2591.—**Roses and Beetles.**—My Roses are every year ruined by large green beetles. Although we kill thousands every summer, their numbers seem to increase year by year. Can any one tell anything about their habits, their resorts during the winter, breeding places, &c.?—W. R. BURGESS.

2592.—**Climbers for Winter Garden.**—I am erecting a winter garden in South Kensington, 30 ft. square, to be kept at a temperature of not less than 60°. I should be extremely obliged for a list of the best evergreen creepers to plant round the walls, which will be covered by trellis work.—H. B. F.

2593.—**Lilies Unhealthy.**—I should be glad to know why my Japanese Lilies are spotted, and the leaves showing signs of decay at the axil? One shoot on a plant will be quite green and strong, and others affected in the way described. Is green fly responsible? I can think of no other cause. This applies both to plants in pots and in the ground.—LILY GROWER.

2594.—**Grubs in Carrots.**—I have had two beds of Carrots destroyed within the past ten days by a little white maggot about one-fourth of an inch long. Each Carrot contains about one hundred of them; they seem

to have commenced to bore at the point of the root and worked up to the top. Perhaps some reader will be kind enough to give a remedy for the destruction of the above insects: also, would they be injurious to any other crop put in the same ground?—J. M. G.

2595.—**Drosera rotundifolia.**—What is the summer and winter treatment of this plant, particularly the latter, as it seems difficult to preserve so as to come up again?—M. Davey.

2596.—**Sowing Annuals and Perennials.**—I have a large garden near London very open and exposed to the street, and often to a cutting wind. Some parts of it, however, are protected. I should like some one to tell me what seeds of hardy perennials I should sow now to yield plants to flower next year. May I safely sow annuals in the autumn, where they are to grow? and what kinds?—Talbot.

2597.—**White Worms in Carrots.**—Can any one suggest a remedy for this? My crop of Carrots is being entirely destroyed.—Monaghan.

2598.—**Blood and Bone Manure.**—How should blood and bone manure be used, and in what quantity?—Subscriber.

2599.—**Marsh Sundew.**—Can any reader give me any information as to the cultivation and habits of this interesting little plant?—E. C.

THE HOUSEHOLD.

STRAWBERRIES.

Strawberries, now plentiful, are usually in season from June to July. Plants forced in spring often fruit in the open air in autumn. The Quatre Saisons, a small and good fruit, bears through the summer and autumn. The Grove End Scarlet is one of the best for preserving, whilst for dessert purposes none are equal to the British Queen. Sir Charles Napier and Sir Joseph Paxton are the best for general culture, as they are good for either dessert or cooking.

Strawberries and Cream.—Procure the fruit when it is freshly gathered and just ripe. If it is not to be eaten immediately, keep it in a cool place till wanted; but the fresher it is the better. Do not wash the berries unless it is absolutely necessary. If, however, they are dusty or not quite fresh, they may be cleansed and freshened by passing them quickly through a basin of cold water. They should not be allowed to remain in it one instant. If the Strawberries have been gathered in rainy weather, it is very desirable that this cleansing process should be performed. Strawberries are very delicious served with thick cream and finely-powdered sugar. These accompaniments should be sent to table separately, as if the sugar is put upon them even for a short time it will draw out their juice and change their colour.

Bottled Strawberries.—Gather the Strawberries in dry weather when they are ripe, but not over-ripe. Pick them without bruising them, and put them into perfectly dry wide-mouthed bottles. Shake them down, and fill the bottles with clear syrup made by boiling three-quarters of a pound of refined sugar with half-a-pint of water. Cork the bottles tightly, and tie them down. Wrap straw round them to keep them from being broken, and put them into a large stewpan with cold water up to their necks. Let the water be made to boil, then draw the pan to the side, and let it simmer gently for ten minutes. Take the pan off the fire, and leave the bottles untouched till they are cold. Refit the corks, tie them down again, if necessary wax them over, and store for use. Time to simmer, ten minutes.

Strawberries for Flavouring.—Gather the fruit in dry weather, pick it from the bolls, discard any bruised or unsound berries, and weigh it with an equal weight of finely-powdered sugar. Fill perfectly dry wide-mouthed bottles with alternate layers of fruit and sugar, and shake them gently to mix them. Cork the bottles closely, and cover the corks with bladder which has been cleaned, dried, and moistened with spirit on the side which is to be next the cork. Store in a cool dry place. The Strawberries should be perfectly fresh when they are thus preserved.

Compote of Strawberries.—Take a pint of freshly-gathered ripe Strawberries. Pick them and put them into a bowl. Pour over them a little clear syrup which has been made by boiling a quarter of a pint of water with five ounces of sugar for ten minutes. Cover the bowl containing them with a plate, and let them stand for an hour or more. Drain off the syrup; boil it for a few minutes, skim it, and strain it over the Strawberries piled in the centre of a compôte-dish. The flavour of this dish will be greatly improved if a wine-glassful of Red Currant juice is added to the syrup. When it is at hand a glass of maraschino may also be added with advantage. For a superior dish, the syrup, after being flavoured with maraschino or kirschenwasser, may be set in ice till it is almost frozen, and in this condition poured over the fruit. Time to soak the Strawberries, one hour.

Preserved Strawberries.—The fruit must be gathered in very dry weather. The stalks must be left on. Place the Strawberries upon a china dish without touching each other. Strew over them double their weight of sifted loaf sugar. Have ready also some very ripe Strawberries with their stems picked off. Bruise these in a basin into a mash, and mix with them their weight in sifted sugar. Stand the basin well covered in a stewpan of boiling water. Place it over a slow fire, and there let it remain until the juice of the Strawberries is drawn out and begins to thicken. Strain this juice through a muslin rag into a pan, pressing the pulp well; boil and skim it, and let it cool. When cold, put the whole Strawberries into this syrup, together with all the sugar strewed over them. Place them on a stove till they become a little warm; take them off and let them cool, then heat them again. Continue this several times until they are clear, warming them gradually, but taking care that they never approach a boil. If ever you perceive a tendency in any of them to break, remove them instantly from the fire, and do not replace them on it until they have become quite cold. When they are sufficiently clear, put them with great care into pots.

Strawberries Preserved in Wine.—Take the fruit when perfectly ripe and fresh; pick it, and put it immediately into dry wide-mouthed bottles. Sprinkle amongst it four ounces of powdered sugar with each pound of fruit, and let the bottles be filled to the neck. Pour in good sherry or Madeira to cover the fruit. Cork the bottles securely, wax them down, and store in a cool dry place.

Strawberries Preserved Whole.—Take perfectly sound ripe Strawberries which have been gathered in dry weather; pick and weigh them. Put them in layers on a large dish, and sprinkle finely powdered sugar between the layers—a pound of sugar will be required for every pound of fruit. Let them stand all night. Next day put the whole gently into a clean preserving pan. Let it boil; shake the pan to keep the Strawberries from burning, and pass a spoon round the edges, but be careful not to crush the fruit. Remove the scum as it rises, and boil the fruit gently for a quarter of an hour. Drain the juice from the berries, and boil it separately for half an hour. If liked, a pint of Red Currant juice boiled to syrup with half a pound of sugar may be added for each pound of Strawberries, and this will greatly improve the flavour of the preparation. Pour the boiling juice upon the fruit, put both again into the pan, and boil the mixture for a quarter of an hour, or till the juice will set when a little is put upon a plate. Put the preserved fruit into jars, cover in the usual way, and store in a cool place. Strawberries preserved thus are very good served in glasses mixed with cream.

Strawberry and Custard Pudding.—Take four ounces of finely-grated bread-crumbs. Place four tablespoonfuls of Strawberry jam in a buttered pie-dish, cover this with the bread-crumbs, and add some good nicely-flavoured custard made with a pint of milk, two eggs, and a little sugar. Stir the custard over the fire till it begins to thicken, pour it gradually upon the bread-crumbs, and bake the pudding in a moderately heated oven. Time to bake, half an hour.

Strawberry Blancmange.—Take a quart of clear stiff blancmange made with isinglass or gelatine. Sweeten this, and stir into it the juice which has been drawn from a quart of fresh Strawberries. Mix the ingredients thoroughly, put the blancmange into a damp mould, and leave it in a cool place till set. Turn it upon a glass dish, and serve. To draw the juice from the Strawberries, pick them, spread them on a large flat dish, and sprinkle over them about six tablespoonfuls of powdered sugar. Let them stand for six or eight hours, and pour away for use the syrup which has flowed from them.

Strawberry Cardinal.—Hull a quart of ripe, finely-flavoured Strawberries, and discard all berries that are unsound or bruised. Sprinkle upon them a pound of powdered and sifted sugar, and pour over them half a bottle of Rhine wine. Cover closely, and let them stand in a cool place for half an hour. Just before they are to be served, pour over them the remainder of the wine, with another bottle, either of Moselle or of the same wine. Add a bottle of seltzer and serve. If liked the liquor may be strained and bottled for use.

Strawberry Cheesecakes.—Take a quarter of a pint of ripe, finely-flavoured Strawberries, measured after the stalks have been picked from them. Bruise them thoroughly with a wooden spoon in a basin, and mix with them a heaped tablespoonful of powdered sugar and two well-beaten eggs. Line some patty-pans with good pastry, three-parts fill them with the mixture, and bake in a well-heated oven. If fresh fruit cannot be had, Strawberry jelly may be used instead, and then no sugar will be required. Time to bake, ten minutes.

AQUARIA.

MAKING AN AQUARIUM.

Some few months back I was desirous of making a tank for my fish &c., and to give them as near as possible an approach to their original habitation, I proceeded in the following way:—Obtaining a sheet of zinc measuring 31 in. by 24 in., I cut and bent it into the shape of a large oblong square box without a top. By allowing a depth of 7 in. for the sides, I had a tank of 24 in. by 17 in. I fastened Virgin cork to its inner sides with Proutts' elastic glue, which, as far as my experience goes, never taints the water or does injury to the fish. A small movable fountain is fitted up in the centre. An inch from the top a waste pipe is inserted; also in the bottom is fixed a piece of 1-in. pipe with a water-tight cap, which on being removed allows the water to run out in a very short time for the purpose of cleaning the receptacle out. The bottom is bestrewed with road-grit and shingle, and a few aquatic plants are placed in the cork. The tank has one side resting on the sill of a window at the back of the house, the others being surrounded with a flower-box constructed the same depth as the aquarium, and the outside is decorated with rustic woodwork. The whole is under glass and in a south-eastern position, thereby receiving the benefit of a few hours' morning sun in bright weather. Convolvuluses, Ferns, Mignonette, and the Canary climber are growing in the box surrounding the tank. I may here mention that I have continually used Virgin cork decorations for my aquariums, and have not found that it affects the water or fish in the least. Before placing new cork in the tanks I sunk it in water for a week, and this doubtless was the means of drawing off any offensive matter the cork contained; and when taken out and thoroughly dried in an oven, fastened it in the way indicated. To fit this up the expense has been from 3s. 6d. to 4s., the sheet of zinc costing the most, viz., 2s. Here, then, is a method by which anyone who has a few spare shillings may have a fish-pond in miniature. Certainly the inhabitants are not seen to advantage, as in a square or round aquarium; but what matter? Such a contrivance is a fair imitation of what they once inhabited, as all light proceeds from above, and not all round, as is the case with ordinary aquariums, when too much will often injure the fish. I find my minnows and carp enjoy their new home exceedingly, and appear quite healthy. If at any time I find they are covered with a white film, I catch and place them on a little silver sand in a plate, with which they soon get smothered, then lightly press one finger on the head of the fish and draw another tenderly up and down the body a few times and then set them free again, and when the sand falls off the fish are quite clear of film. I have done this many times, and have had no fatal consequences arising therefrom. For the newts a piece of cork is kept floating on the surface of the water upon which they can crawl, and this they highly appreciate. I feed these pets on worms, shreds of raw beef or mutton, pills of flour and water, and twice a week throw in a small quantity of Roberts's food for gold fish and minnows, which may be purchased at 2d. per

packet, and this they seem desperately partial to. A few weeks ago I brought home about thirty sticklebacks from a running stream in the country, and out of that number only two have survived; and I have come to the conclusion that this species must be either very delicate and die on account of removal, or else because the London water is so different from brook water. I feel sure it cannot be for the want of vegetation in the tank, as I have sufficient of that. I placed a few river minnows in an aquarium in company with six or eight young tadpoles, and shortly after I found the fins and tails of the minnows bitten off, and some nearly to the flesh. If any one can tell me through these columns if the probability is that the tadpoles did the mischief, I shall feel obliged. Nothing besides was placed in the water with them. NEWT.

BEES.

WE hear great complaints in many directions as to the loss of queens consequent upon the destructive nature of the past year's weather; and now many, finding that their bees are active about the mouth of the hive, but seem neither to work nor inclined to swarm, learn, on examination, that there is no queen bee, and that the stock is practically good for nothing. If it were possible to provide queens for such forlorn stocks, a great benefit would result; but that is not an easy matter, as spare queens are rarities. To ascertain the condition of a doubtful looking stock, it is well to prevent the bees from coming outside in the mornings, and when convenient obtain a piece of the fungus commonly used for the purpose, set it on fire, and place it just within the entrance. The fumes will soon make the bees insensible, and when so the hive may be lifted off and the bees thrown out upon a cloth spread on the ground. They then may be examined as well as the comb within the hive, and if a queen is not to be found, then the hive or stock is useless, unless a strange queen can be provided. If this is not possible, then it will be advisable to endeavour to unite the old stock with another that has a queen, but is perhaps weak, and to accomplish this it will be necessary to simultaneously send both stocks to sleep as before, throw each lot out together upon a cloth, and stand over them, tilted partly on one side, the hive which held the stock having the queen bee. The two stocks will then as they revive unite in the one hive, and most probably will agree to live in peace. In the case of strong stocks, whether old or new, it is time that supers were placed on the hives, to prevent if possible further swarming, and to secure the best of all the honey, which in the supers is pure virgin and of the finest quality. A. D.

I shall be glad if some practical bee-keeper will give me a few hints in GARDENING respecting the practice of stupifying bees by means of burning fungus, &c., as my first experience has been most unfavourable, having lost my best stock. On the eve of swarming I gathered 13 lb. of delicious honey, but at the expense of days of great suffering to the industrious insects before their final collapse. I proceeded as follows: Procuring a shilling packet of fungus from Messrs. Neighbour and Sons, I followed their directions by igniting one half the quantity in a empty hive, over which the full one to be plundered was placed, and soon heard the bees dropping into the lower one. When all was quiet I separated the hives, expecting to see nearly the whole of the bees below, but found only about an eighth part of them. The combs of the full hive appearing to be closely packed, I carefully removed the stupified bees from the empty hive, and again placed the full hive over it, burning the second half of the packet, the result being as at first, viz., the stupefaction of about one-eight part of the bees only. I was obliged to repeat the operation five times, using latterly brown paper, as my fungus was quite exhausted, and even then, when I turned up the full hive and allowed it to remain exposed to air and light, about 500 poor suffering bees crawled out, covered with honey, having tried to escape the fumes by hiding in the half-filled cells. Well, I placed the hive into which I had introduced them on its stand, expecting to see them active enough next day, but only a dozen made their appearance, and these wretchedly ill. The next day after about fifty crawled out, but soon dropped to the ground, and this they continued to do until the ground around the hive was covered with half-dead bees. When revived by a warm sun they seemed active enough, but could not fly far, and when placed in front of the hive crawled in more dead than alive. Even the most active in the hive would suddenly run out, as if frantic, and drop from the hive board. Upon raising the hive yesterday, a week after operating, I found that they had eaten the honey I placed for them, crawled out, and left but about sixty behind. These poor insects tried to hide in the empty cells of the comb I had introduced, but pity, not cruelty, induced me to drown them. But two dead bees —drones—were in in the hive.

Is this a fair sample of the humane system? If so, by all means let us continue to smother the bees outright. If not, what was the cause of my failure? Can any one tell me? Was the brown paper hurtful? If so, the first two lots should have recovered, as none was used to them; besides, the bees out for the day escaped the smother altogether. Why should they all die, or so nearly die, that it was a mercy to kill them?

I continue to find half-dead bees upon the lower leaves of shrubs 10 ft. from the hive.

NOVICE.

Book on Bee Keeping.—*Cottager.*—"Manual of Bee Keeping," by John Hunter. London: Macmillan & Co.

POULTRY.

Cramp in Chicks.—Cramp in chicks at this time of year must arise from some error in feeding. Probably their food is too soft, and they have not sufficient access to sand and small gravel, without which they cannot digest their food. For the first week after chicks are hatched they should be kept to split grits and hard boiled egg, mixed with stale crumbled bread; the second and third week substitute whole grits, with one meal a day of Spratt's Poultry Meal, and after that they should be ready for good sound Barley twice a day, Spratt's food once. Chicks should never be allowed to run on damp ground till after the third week. If very delicate, bread soaked in ale with a pinch of Cayenne strengthens them.—C.

Disease in Fowls.—Two sources of disease in fowls are, want of Grass or green stuff and a dust bath. I throw all the Grass of a small plot to the fowls; not one ever fails. I have forty-five in a space of 100 square yards.—MABOR.

Malt Dust for Fowls.—Can any reader tell me if malt dust is a good thing to give to fowls? if so, in what quantities must I give it them? and with what mixed if not alone?—G. A. F.

Ventilating Hen Houses.—I have built a hen house, 9 ft. long, by 5 ft. deep, by 4 ft. broad, and should be glad to learn a simple way of ventilation. Would an open space top and bottom of the door covered with perforated zinc be efficient? How many fowls should be put in a house of that size?—C. W.

Rats in Fowl Houses.—I have a fowl house built of wood surrounded with walls of turf, but unfortunately am much troubled with rats. I have lost many chicks through them. Can any one advise me as to the best way of getting rid of these pests?—H. BULL.

Cats Killing Chickens.—May I suggest a plan to cure cats of chicken-killing which I find successful? It is to catch the culprit and shut it in a small space with a hen who has chickens; if of game breed so much the better. She will generally give the cat such a lesson, that nothing will persuade it to approach the chickens again, especially if a good ducking in a bucket of water follows the performance. I am so pestered with my friend's "pet animals," that I was obliged to get a legal opinion, and was told I was justified in killing cats caught destroying poultry; but of course a friend's "dear tom" must sometimes be spared. I find a terrier with "cat-killing" reputation is a great preventive.—H. B. A.

Dropsy in Fowls.—All high-bred chickens are subject to swellings on different parts of the body. It is a skin affection, and the swelling does not contain water, but air. I have found Spanish chicks especially troubled in this way, and always just before the formation of the quill feathers. I have never lost one since adopting the following treatment: Give the chick a small teaspoonful of castor-oil, containing as much flour of sulphur as will lie on a threepenny-piece, and rub dry flour of sulphur thoroughly into the skin of the bird, especially under the wings. If the swelling is very large, it may be pricked with a needle.—C.

Eggs Without Shells.—Every morning on going into the chickens' house I find under the perch a shell-less egg attached to the dung, and it appears to be emitted with the dung; sometimes it has no yolk, sometimes it is a perfect egg minus the shell. It is not for the want of mortar, bones, oyster shells, or such like, for we have splendid eggs, usually with shells hard and thick.—J. H. B.

Single or Double Combs in Cockerels.—This depends entirely on the breed, A Spanish cockerel with a double comb would be worthless, and a white rose comb Dorking with a single comb equally bad. With cross breeds it is quite unimportant, as they are of no use for show purposes.—C.

Turkey Eggs.—Turkey eggs can be hatched under hens, but it is best to let turkeys hatch their own eggs. It is rather late to sit them now, but we should try some.

HOME PETS.

Canaries Losing their Feathers.—As to the cause of canaries casting their feathers at a wrong time, it is most probably from the birds living in a draught; nothing throws them into the moult so soon and prevents their singing. This is about the season they begin to change their feathers, though rather too early. When moulting canaries do not sing, but begin again in September if placed in a good situation out of draughts and gas. The irritation is from their new feathers coming. Rape and canary seed mixed ought to be the best food; now and then Groundsel, Chickweed, Lettuce, Shepherd's-purse, Celery, and Apple. During breeding and moulting season, a little hard-boiled egg chopped up with some soaked bread (all water well squeezed out), and a small pinch of Maw seed once or twice a day. Care must be taken to keep the cage clean, and plenty of gritty sand and fresh water; a bath they require every day if they will take it.—P.

King and Queen Parrots.—Will "A. D'A.," who gave a description of the king and queen parrots in GARDENING for October 25 last, kindly say where a queen parrot can be obtained? I have a fine king parrot, and would like to find him a mate. Also of what country are they natives? what kind of nest-making materials they will require? if the young require any particular kind of food? and if the parrots will live out-of-doors during the winter? I have also a light green parrakeet with red beak, smaller than the king parrot. Can "A. D'A." tell me its name, and from what country it comes? Also if it and the king parrot ever learn to talk?—E. M. H.

Tortoise in Gardens.—Can any reader give me an idea of the habits, likes, or dislikes of the tortoise? I bought one some days ago and put it in the garden. Beyond that I know little or nothing; have given it soaked bread, which I do not think it has touched. Should it have a dry place to go in to sleep on out of the rain? and in winter do they bury themselves, or ought they to be brought into the house? The only apparent object of this one is to hide itself.—K. A. H.

Rabbit with Matted Hair.—My son has fancy rabbits, and of five young ones one (the male) has a very long white coat, which, from its length, we suppose has got matted. What can be done? He has put him in a hutch alone, thinking the four others for warmth laid too close to him. He has pink eyes and would be lovely if it were not for his long matted hair.—MIGNONETTE.

Canary Mopish.—I have a canary which till lately has always been in very good health. About a month ago I discovered lice on the water in which he washes. This last week I have seen nothing of them, but he is mopish, rough in plumage, and his breath is short and sharp. When he is sleeping, he seems as though he would tumble off his perch with every breath he draws. He is hanging in a sunny window free from draughts and eats well. He does not appear to be moulting. What should I do with him?—BLUEBELL.

Food for Birds. If "J. R. B." will refer to GARDENING ILLUSTRATED for June 5, he will find an answer to his question on strengthening food.—FERNDALE.

COVENT GARDEN MARKET.

WHOLESALE PRICES.

Cut Flowers.—*Per dozen bunches.*—Anemone, 2s to 6s; Azalea, 4s to 9s; Cineraria, 6s to 12s; Ferns (various), 3s to 9s; Heliotrope, 6s; Lily of the Valley, 4s to 12s; Lilac, 2s to 8s; Mignonette, 4s to 9s; Narcissus, 6s to 12s; Pelargoniums (zonal), 3s to 6s; Pelargoniums (large flower), 6s to 12s; (double), 6s to 12s; (Rose-scented leaf), 6s; Spiræas, 6s to 12s; Tropæolums, 1s to 3s; Tulips, 4s to 9s: Violets (blue), 1s to 2s.—*Per dozen flowers.*—Abutilon, 4d to 6d; Arum Lilies, 3s; Tree Carnations, 1s 6d to 3s; Eucharis, 4s to 6s; Gardenias, 2s to 8s; Roses, 1s 6d to 6s.—*Per dozen sprays or trusses.*—Bouvardias, 1s 6d to 3s; Fuchsias, 2s to 4s; Primulas (double), 9d to 1s; Stephanotis, 2s to 4s.

Plants in Pots.—*Per doz.*—Arum Lilies, 9s to 12s; Adiantum cuneatum (ordinary), 6s to 18s; Begonias (flowering), 6s to 12s; Begonias (fine-foliaged), 6s to 12s; Bouvardias, 12s to 18s; Cineraria, 4s to 12s; Daphne indica, 4s to 6s; Dracæna (green-leaved kinds), 12s to 30s; Euonymus, 4s to 12s; Euonymus (variegated), 6s to 18s; Ferns (greenhouse and stove, various), 6s to 18s; Ficus elastica, 18s to 60s; Fuchsias, 6s to 12s; Gardenias, 24s to 36s; Lily of the Valley, 12s to 24s; Mignonette, 6s to 9s; Nasturtium, 3s to 6s; Palms (small), 18s to 60s; Pelargoniums (fancy), 9s to 24s; Pelargoniums (scarlet), 4s to 9s; Pelargoniums (double), 6s to 12s; Roses (hybrid perpetual), 12s to 24s; Spiræa japonica, 6s to 18s; Selaginellas, 3s to 4s; Virginian Creepers, 6s.—*Per pair.*—Maiden-hair Ferns (large), 4s to 7s; Palms (large), 15s to 42s; Amaryllis, 1s 6d to 3s each.

Fruit.—Apples (culinary), per bushel and barrel, 9s to 30s; Cobs and Filberts, per 100 lb, 120s; Grapes (English hothouse), per lb, 2s to 6s; Lemons, per box, 30s to 35s; Oranges (various kinds), per 100, 8s to 16s; Pomeloes, per dozen, 3s to 6s; Pine-apples (St. Michaels), each, 5s to 15s; Pine-apples (English hothouse), per lb, 2s to 3s; Strawberries per lb, 9d to 2s; Gooseberries per qt, 3d to 6d.

Vegetables.—*Per* 100.—Asparagus, 3s to 5s; French Beans, 9d to 1s. *Per dozen bunches.*—Carrots (outdoor), 4s to 5s; Watercress, 6d to 8d; Leeks, 1s 6d to 3s; Mint, 4s to 6s; Parsley, 4s; Turnips, 1s to 1s 9d; Radishes, 9d to 1s; Herbs, 2d to 6d. *Per doz. punnets.*—Cress, Mustard, or small salad, 2s. *Per dozen.*—Cucumbers, 4s to 7s; Endive, 2s to 3s; Lettuce, 6d to 1s. *Per bundle.*—Horseradish, 3s to 6s. *Per lb.*—Shallots and Garlic, 6d; New Potatoes, 1d to 3d. Chervil, per punnet, 3d; Corn Salad, per half-sieve, 2s; Mushrooms, per pottle, 1s 3d to 1s 9d; Potatoes (general store, round kinds), per ton, 100s to 200s; Kidney, per ton, 120s to 180s; Parsnips, per tally, 5s to 7s; Rhubarb (per dozen bundles), 2s to 3s; Spinach, per half-bushel, 2s 6d; Tarragon, per bunch, 6d.

GARDENING

REGISTERED FOR TRANSMISSION ABROAD.

THE CALIFORNIAN AND OTHER LILIES.

THERE is now such a variety of Lilies, that a really beautiful garden may be made of them alone. Many of the kinds commence blooming early in June, and others keep up a succession till far into the autumn. Thus with a number of well-selected kinds a fine display may be had for at least five months in the year. Lilies again possess other advantages besides variety of flower and long continuance of bloom—they grow of all heights, so that they can be used in any position. Beginning with such kinds as L. Thunbergianum, which yield blood-red and apricot-coloured blossoms when little more than 1 ft. high, we can have kinds gradually increasing in height till we reach the fine spotted crimson and orange-flowered L. pardalinum, which attains a height of 8 ft. in good soils. A

HUMBOLDT'S SPOTTED ORANGE LILY (LILIUM HUMBOLDTI).

visit just now to the Hale Farm Nursery is well repaid if only to see the collection of Lilies, which are just now at their best. We never remember seeing the North American, and especially the large Californian, kinds so grand as they are there this season. Of L. pardalinum there are large masses in full flower, ranging from 5 ft. to 7 ft. high, and the gigantic form of it, named Robinsonianum, is even taller and more robust. L. californicum, too, has attained remarkable size and vigour, and is unsurpassed in brightness among all the forms. A late-flowering variety, named by Mr. Baker Bourgæi, is a very desirable one, though the buds are not yet expanded. The stately L. giganteum is likewise finely in flower, some specimens being furnished with fifteen flowers, all bright and perfect on a stem about 5 ft. high. L. Browni, perhaps the finest of all Lilies, is unusually fine this season, the large beds of it now in flower at Tottenham being a sight well worth seeing. It yields large, chocolate-coloured buds, which, when they expand, reveal a perfect trumpet-shaped flower of ivory whiteness. The old Martagon and its numerous forms, including the handsome dalmaticum, album, Cattanæ, &c., are still in perfection, as are also the late varieties of L. davuricum, Thunbergianum, and others of a similar type, together with the rarer L. philadelphicum and L. canadense in all its varieties, including the distinct-looking L. parvum. These are all in fine flower, as is also the singular-coloured L. testaceum. The beds of L. Krameri have for some time been very attractive, and presently L. longiflorum and its varieties will be equally showy. The noble-looking L. Humboldti grows remarkably fine in the stiff soil here, and is just expanding its large pyramidal heads of flowers.

The following is a list of Lilies in flower near London during the past week :—

Lilium concolor	Lilium auratum
Szovitzianum	canadense
pomponium	parvum
pulchellum	Parryi
davuricum	giganteum
monodelphum	Humboldti
carniolicum	japonicum
Martagon & vars.	croceum
umbellatum	Browni
elegans	pardalinum
columbianum	californicum
Krameri	Thunbergianum

HARDY BORDER FLOWERS.

THE hardy herbaceous border is the best feature of the flower garden, though commonly regarded as the worst. When well made, well stocked, and well managed, it presents us with flowers in abundance during ten months out of twelve, and in the remaining two blank months offers some actual entertainment, and many agreeable hints of pleasures to come, to make an ample reward for the comparatively small amount of labour its proper keeping will necessitate. Given a few trees and shrubs, a plot of grass, and comfortable walks, the three first essentials of a garden, and a collection of hardy herbaceous plants is the fourth essential feature, and may be the last; for the bedding system may very well be dispensed with in a homely place, provided the hardy flowers are admitted and cared for according to their merits. It may be that many a reader of this will be disposed to question whether Pelargoniums should be swept away to make room for Lilies, and Verbenas denied a place because of the superior claims of Phloxes, but such a question we do not propose; our business is to point out that the bedding system is an embellishment added to the garden; the herbaceous border is a necessary fundamental feature. Therefore we ask for the establishment of a collection of herbaceous plants before preparations are made for a display of bedding, and our advice to those who love their gardens and walk much in them, and find amusement in watching the growth of plants, and in contrasting their various characters and attractions, is, that they should seek to develop the herbaceous department, and so become acquainted with its full capabilities. In this pursuit enthusiasm may be manifested without incurring the reproach of reason, for it is a truly intellectual pastime, and demands the practice of patience and the exercise of thought in no small measure from those who would know more of it than appears upon the surface. Let us for a moment consider the claims of the herbaceous border to better regard than is usually bestowed upon it.

It is an important characteristic of the herbaceous border that its proper tenants are hardy plants that need no aid of glass or fuel for their preservation during the winter. In the cultivation of bedding plants we may fairly reckon on a brilliant display for three months, and it may extend to four—say from the 1st of June to the 30th of September, but the herbaceous border will be gay from the end of April, or long before that, to the middle of October, a period of six months, and will offer us a few flowers in February, and a few in November and December, and in a mild winter will not be utterly flowerless even in January. It would be an exaggeration to say that the herbaceous border is capable of a display of flowers all the year round, but it is very nearly capable of a consummation so devoutly to be wished. To the advantages of hardiness and continuity of bloom must be added a third and grand qualification of a distinguishing kind—that of variety. It is scarcely an exaggeration to say that the varieties of form, colour, and general character amongst hardy herbaceous plants is without limit; but, as variety can be obtained amongst ugly plants, we are bound to add that the proper occupants of the garden we are considering are all beautiful, and a considerable proportion are well-known favourites. Nevertheless it must be admitted that with all their good claims to loving regard, the hardy herbaceous plants obtain but scant attention, and tens of thousands of persons who know that Verbenas are somewhat showy when in flower, and would like to grow thousands of them, are prepared any day to ignore the whole tribe of herbaceous plants as weedy things that have had their day, and, with the exception of a Lily or two, and perhaps a Hollyhock, deserving of a place only in the unsavoury hole where Grass-mowings and the sweepings of the poultry house are deposited with a view to a "mixen." It ought to be needless to attempt this vindication, but we feel bound to urge that every rational development of the hardy garden will prove advantageous to the lover of flowers, as tending both to lessen the expense and labour which the keeping of a garden necessitates and considerably augment the pleasures that it is capable of affording as the seasons change and the year goes round.

As hardy herbaceous plants of some kind or other will grow in any soil and any aspect, not one single square foot of ground in any garden need be utterly barren. A tuft of Solomon's Seal in a dark spot where the soil is quite unfit for better plants may be better than nothing. Sunny, shady, hot, cold, dry, moist, or even wet positions have their several capabilities for hardy plants, and we have but to make our selections prudently to ensure a plentiful clothing of herbage and flowers for every scene. But an herbaceous border designed for a good collection of plants should consist of good deep loamy soil; the greater part of it should be fully exposed to sunshine and breezes, but it is well to have some extent of ground partially or considerably shaded to provide the greatest possible variety of conditions for the greatest possible variety of the forms of vegetation. In preparing a border, in the first instance the ground should be well dug two spits deep, and at the same time liberally manured. In the case of an old border requiring improvement, it may be well to lift all the plants and "lay them in" safely while the border is trenched and manured; or it may suffice to leave the good plants undisturbed and provide sites for additional planting by opening holes and digging in plenty of manure. In any case we would earnestly advise that herbaceous plants should be thoroughly well cultivated, even if, to do full justice to them, the bedding display has to be contracted or abolished. The majority of the best herbaceous plants—Hollyhocks, Phloxes, Lilies, Tritomas, Delphiniums, Pinks, Chrysanthemums, Primulas, Pyrethrums, Potentillas, Anemones, Ranunculuses, Irises, Œnotheras, Foxgloves, Campanulas—require a deep, rich, well-drained loam, but will grow well in clay that has been generously prepared, and need not be despaired of altogether where the soil is shallow and sandy, provided there are appliances available in the shape of manure, mulchings, and waterings, to sustain them through the hottest days of summer. It must not be forgotten, too, that if the herbaceous border is formed on a somewhat good soil—say a soil that will grow a Cabbage—and in a position open to the sun and the health-giving breezes, it may be enriched by the addition of Roses, Stocks, Asters, Zinnias, Balsams, Dahlias, and many more good things that "need only to be seen to be appreciated."—*The Amateurs' Flower Garden.*

Home-grown Spiræa japonica.—We have become so accustomed to let the supposed superiority of imported productions pass unquestioned, that I suppose any one who enters a plea in favour of home-grown Spiræas will be looked upon with distrust. But why a plant that delights in abundant moisture and a moderate amount of sunlight cannot be grown to perfection without a preliminary sea voyage passes my comprehension. We are not yet clear of the effects of the miserable season of 1879—cold, wet, and sunless—yet our Spiræas, even on north borders that did not get the little sunshine with which we were favoured, are flowering excellently, and large clumps, lifted with balls of earth and set in Vineries for a few days, have been good throughout the season for decorative purposes. Any one having old forced plants should try them on a good piece of ground, and after one season's rest compare the result with imported plants. If they do not hold their ground against the ordinary run of such plants, I shall be disappointed, as I see no reason why this Spiræa cannot attain equal perfection here as on the Continent.—J. G.

The Culture of Pinks.—The culture of the Pink, either for exhibition or decoration, is so simple, and the outlay so small, that it is a wonder to me how it is it should come to be so neglected of late years, but, like some other old-fashioned flowers, it will perhaps ere long come to the front. Pinks may be got from any nurseryman almost at from 3s. to 6s. per dozen pair. The best time to get them is in August or beginning of September, when you can get newly-struck pipings. Place them at once in a sunny situation; if situated in a smoky town a cold frame will be needed; if the air is clear an open bed will do; and when once planted openly, scarcely any care is needed from the time they are planted till they begin to push up their flower-stems in the spring. The soil should be quite fresh, and very little or no manure is needed; and those planted in the frame will need all the air possible, except in very frosty weather. Plant out in spring as early as the weather will permit, and as soon as they begin to grow, mulch the top of the bed with equal quantities of well-rotted horse dung and leaf-mould 1 in. deep. They will then push on their new growth fast. As soon as they begin to send up their flower-stems, give another good mulching of sifted manure, adding about one-fourth of fresh soil. Get some sticks (I use Willows) and tie each flower-stem to a stick. Let them grow on, keeping them tied up the stem till they begin to flower. Then give another top-dressing with new horse droppings if it is at hand, and it will help the side-shoots on so that they will not be robbed by the first blooms. It is now time to multiply your stock. If the plants have made any breed in July, cut with a sharp knife the shoots that are the strongest, cut the ends of the grass off, and cut the shoot two or three joints below the grass or leaves. Prepare a bit of ground as follows: Scatter on the surface a little salt, then riddle on 2 in. deep of fresh soil, prick your pipings in, and put a light or hand-glass over them, and they will be struck in a few weeks. —LACY GREEN.

Planting out Fuchsias.—Do the readers of GARDENING know how well greenhouse Fuchsias can be hardened into becoming out-

SOME HARDY LILIES NOW IN FLOWER IN LONDON GARDENS.

door ones? I plant them out in June, and then about November I cut down the branches and pile ashes over the roots. They will throw up fine shoots next summer and bear very good flowers. This plan answers even in a cold climate. They might be planted out much later in the year after flowering in the greenhouse.—HAREWOOD.

East Lothian Stocks.—Many sow these in August, and no doubt it is a good plan; but if they are sown early in the spring in heat, pricked off when large enough to handle, and treated liberally until they are fit to plant out, say early in May, they will be in flower in July. In warm, porous soils early planting is desirable, as it enables them to get well established before hot weather sets in. When the seeds have been saved with care, these Stocks are well adapted for planting in masses in the flower garden, as a considerable proportion of the plants will produce double flowers; and what few single ones there are do not, as is the case with many other kinds of Stocks, run up with a loose, straggling habit, but retain the compact orderly style of growth peculiar to this variety; therefore the fact of these flowers being single is not noticed so much, as it does not bring them objectionably into prominence. They will flower beautifully all through the autumn; in fact, unless the winter be severe or very wet, there is no cessation in their flowering. Continual wet weather and a water-logged soil are more fatal to them than even frost. At present this variety of Stock does not appear to have run into so many colours as other kinds, and there seems to be little difficulty in keeping the individual colours distinct. The white variety is especially pure and good.—H.

Tropæolum polyphyllum.—This is one of the most valuable hardy plants ever introduced, not only for its freedom of growth and flower and the readiness with which it may be grown, but also for its picturesque way of growth, for, while its foliage may form a dense carpet over a bank, the wreaths of flowers usually throw themselves into irregular windings and groupings.—V.

Propagating Pansies.—In order to secure a good stock of any kind of Pansy, it is better to trust to plants raised from cuttings than from seed, as seedlings, although true to colour, have such diversity of shades, markings, and habits of growth, that they cannot be trusted to produce a constant and even mass of colour. Cuttings made of the young growth that comes up from the base of the plants in summer are best, inasmuch as they are firm and generally strike freely. Old blooming wood is usually hollow, and consequently strikes badly. Cuttings may be put in a cool, shady place in sharp sandy soil any time during the next three months. For spring beds none are better than Blue King, Bedfont Yellow, and Snowflake; and of early blooming Violas, none are better than Bluebell, Yellow Boy, and White Swan.—D.

The First Fuchsia (F. coccinea).—This lovely Fuchsia associates well with the ordinary occupants of a mixed border, and is so graceful and beautiful both in growth and bloom as to commend itself to the notice of the most casual observer. It readily adapts itself to any locality, provided the soil be not of the wettest and coldest description, and even then a slight covering of coal ashes after the stems have been cut down in autumn will suffice to protect the roots in winter. In favourable situations it often attains a height of 6 ft. From the axils of the leaves, which are of a fine green colour, beautifully tinged or veined with red, the flowers, which before they fully open are not unlike crimson drops, are produced in profusion during the greater part of the summer. The Fuchsia in question was first put into commerce by Mr. Lee, the founder of the well-known nursery at Hammersmith, who, it is said, obtained it in the following way:—Mr. Lee having heard that in the window of an humble dwelling in Wapping, growing in a pot, was to be seen a beautiful plant with drooping flowers like earrings, his curiosity became excited, and he at once determined to proceed to the locality and see for himself. Once there, he could not disguise his admiration of the plant in question, and soon introduced himself to the owner, whom he found to be the wife of a sailor. After some preliminary conversation, he offered her a golden guinea in exchange for the plant, but this she refused, saying that her "Jack had brought it home from a foreign country, therefore she would not part with it for his sake." After some persuasion, however, and a promise that he would propagate a plant of the same for her, and at the same time placing in her hands all the cash he had about him (about ten guineas), he obtained possession of the plant, which was speedily propagated, and found, as may be imagined, a ready and profitable sale. The fine old Fuchsia gracilis rubra and F. Riccartoni may also be used for outdoor decoration, being equally hardy; but where a strong-growing, free-blooming kind is required for training against a wall or fence, there is, as yet, nothing to equal the old F. corallina.—R.

Humea elegans.—For planting round or near fountains placed in the centre of a flower garden this plant is excellent. Its graceful drooping tresses of silky brownish-orange-coloured flowers, which glitter in the sun, when moved by the breeze, give it a charm beyond description. Whether as a back line to a long border, as a single specimen to let into the lawn, or for the centre of a bed or vase, it is most charming; and as its culture is easy, and its period of beauty extends from May till November, a brief notice of how it may be best grown may not be unacceptable to your readers. Sow the seeds now in a pan of light soil, and place it in a warm frame until the plants are in rough

Humea elegans.—A graceful plant for the garden or greenhouse.

leaf; then remove them into a cool frame, where they can receive plenty of air and slight shading during hot sunshine for a fortnight, when they will be ready to pot off singly in 2½-in. pots, using light rich soil for the purpose, and plunging the pots to the rim in sand or sawdust. Keep them close and shaded until sufficiently strong to stand out when they must be gradually exposed to sun and air, after which they will only require to be covered with a glass sash during cold or wet weather. Shift them into larger pots throughout the autumn and following spring as they require it, taking care not to let them become pot-bound, as their beauty is much lessened by being in any way stinted, either in pot room, moisture, or richness of soil. By liberal treatment they will retain all their foliage in a healthy green state until finally destroyed by frost. During winter, a low temperature, plenty of air, and being kept near the glass suits those intended for planting out better than heat and a close atmosphere. Give plenty of water before turning them out of the pots, and also for a week or two after planting, until they are fairly established in the soil, which should be composed of turfy loam and well-decayed manure or leaf-soil. When kept under glass to flower in pots for indoor decoration, they are not half so beautiful as when exposed to the open air, their colour indoors being a kind of greenish-pink, which gives the plants a sickly appearance. Slightly fumigating them during the spring months will keep them free from insects, which are apt to infest the under surface of their foliage.—J. S.

Garden Ornaments.—In an article under this heading "Newt" speaks of glue in connection with outdoor work. My experience teaches me that the less one has to do with glue for such work the better. French wire nails are the thing; they are to be had of all sizes, and do not split the wood like square nails. "Newt" also tells your readers to use green paint. If they must paint, I would advise them to try the effect of chocolate colour. How it is that gardeners have such a weakness for green paint I do not know; there are very few greens which harmonise with the greens of Nature, and the prevailing gardener's green is enough to turn the whole harmony of Nature upside-down. Why paint such things at all? varnish them if you want them to last a few years longer.—WHITBY.

ROSES.

Propagating Roses.—One of the most successful methods of striking Roses that I have ever found is, when the first flowers of the season are over, and when the shoots which have borne them have pushed the second growth, to take them off when they have reached a half-ripened condition and insert half-a-dozen cuttings together in 5-in. or 6-in. pots in sandy soil. Place them in a cold frame quite moist; shade and keep the frame so close that the air given will not cause them to flag, and in three weeks' time the base of the cuttings will be callused over, when, if the pots are then plunged in a slight hotbed and treated like other cuttings, they will root directly and make useful little plants before the autumn, whereas if put in heat before they are callused over, three-fourths of them will damp off.

Mildew on Roses.—Apart from the unsightly appearance which Roses affected with mildew have, it does them much harm, and completely spoils the autumn bloom which ought to be forthcoming. Therefore, as soon as ever the parasite is seen, means should at once be taken to destroy it; sulphur in some form, either dusted on the leaves or in water, will be found the best remedy.

Climbing Devoniensis Rose.—This is a beautiful Rose for covering a lofty wall, and at this season its flowers are lovely in a cut state. It is often complained of as being a shy bloomer, but it is a rampant grower, and in order to induce it to flower well, the young shoots, which in vigorous specimens are often 10 ft. or 12 ft. long, should be left their full length. The pruning should be confined to thinning out the wood and removing occasionally an old branch to make room for the young shoots, as it is towards the points of these that the flowers are chiefly produced; no shortening should be permitted beyond removing a few inches of the soft points.—E. H.

BONES FOR THE GARDEN.

IN GARDENING ILLUSTRATED, July 10, there appeared an article on "How to Reduce Bones," upon which I beg to offer a few remarks that may be useful to those living in the country who have gardens and may wish to convert bones into a profitable manure. The plan recommended in the article referred to consisted in making a trench some 3 ft. or 4 ft. deep, and filling in the bones between alternate layers of wood ashes. This cannot certainly be considered a rapid or indeed a desirable plan, as the author himself admits that about ten months will be required to effect complete decomposition. Further, if water be added every eight or ten days, as suggested, it is extremely probable that the soluble salts present in the wood ashes would be washed away and pass off in the drainage. But, to my mind, it appears a mistake to bury bones in a cold soil where the temperature must be low, for we know that all animal substances decompose more readily the higher the temperature; and meat is kept in the coolest part of the house to retard this process of decomposition as much as possible.

In dissolving bones we should reverse these conditions and keep the bones in a warm place with just sufficient water to keep them moist, and enough wood ashes to completely cover the several layers of bones. I would suggest that an old tub, placed in the sunny side of the garden, would be a much more convenient receptacle than a trench dug in the cold soil.

With the aid of a bell-shaped iron mortar, which could be obtained for 5s. from any ironmonger, the bones might be first broken up

into ½-inch pieces, and so rendered much more perfectly acted on by decomposing agents, such as the wood ashes already suggested, or by sulphuric acid, if the latter can be conveniently obtained.

It is most desirable that all refuse bones should be made available in some form as manure rather than be allowed to remain, as they too often are, an ever-fertile source of disagreeable odours from the dust-bin. But I go further, and ask how it is that the special chemical manures, which are now so largely used among farmers to supplement the use of farmyard manure, are not more largely employed in our gardens?

It is only necessary to study first the special requirements of our different garden crops, and then to apply the manures that have been found specially most suitable. Among farmers superphosphate and dissolved bones are employed for root crops; while guano, nitrate of soda, and sulphate of ammonia are the dressings used for cereals, such as Wheat, Barley, Oats, &c.

It is to be regretted that the valuable experiments which Mr. Lawes has carried on for upwards of forty years on his estate at Rothamstead have not been brought before farmers and gardeners in some popular form. The very elaborate manner in which the results of these experiments have been published prevents outsiders from deriving the full benefit of the practical knowledge gained after many years of careful research. No doubt this will be done by-and-bye. Many of the special manures that are advertised as intended for garden purposes have no doubt been compounded after careful study of the requirements of plants.

I have myself during the past few years carried out experiments in my own garden with the remaining portion of special fertilisers sent to me for analysis, and the results obtained have been full of interest. It should be remembered that all the valuable elements contained in a mixture of bones and wood ashes, and which are only available as manure after decomposition, can at once be obtained by using superphosphate (phosphate of lime dissolved by acid) and guano with some muriate of potash. Thousands of tons of superphosphate and guano are used by farmers every year, and doubtless in the future we shall find these fertilisers employed largely in our gardens.

79, *Mark Lane, London.* John Hughes.

FRUIT.

Large Strawberries.—Some Strawberries shown at the Brighton Show the other day, by Mr. Rutland, from Goodwood, created quite a sensation, being admitted to be the largest ever seen. Some idea of what they were may be gleaned from the fact that eight weighed 1 lb. 1 oz. One measured 3¾ in. across it and several 3½ in.; they were not only large, but a very abundant crop, and have been the admiration of all who have seen them. So much for deep cultivation. Very little rain has fallen at Goodwood this season compared with many parts of the country, and not one drop of water have they had but what has fallen from the clouds.

Figs Trained and Untrained.—Some are of opinion that Figs on open walls are more satisfactory left to grow wild than trained. The reason for this is obvious: the training was not suited to the requirements of the subject dealt with. I have myself seen fruit in abundance in exceptionally fine seasons on trees uninterfered with, but the crop was certainly not so regular, fine, or satisfactory as that on trees which were systematically trained so that the maximum of heat and light might reach the useful bearing wood, and the strength of the tree be directed towards its production instead of being wasted on useless watery growth. My own impression is that no fruit tree better repays a little extra attention than the Fig.—J. G. H.

The Lady Apple.—This beautiful little dessert Apple, the Pomme d'Api of the French, will soon again be seen in the windows of the fruiterers' shops in Covent Garden, where its handsome form and brilliant colours never fail to excite admiration, and until late in spring boxes of perfect fruits of it may be obtained. It is by no means a new Apple; on the contrary, it was once said to have been known and appreciated in the time of Pliny. It is now thought to have been, originally, a French Apple, obtained from a wild variety found in the forest of Apis, in Bretagne. In Normandy it was well known in 1690, and was then called Gros Apis and Long-bois. The fruit of this Apple, which should be gathered as late as possible, should be thinned where it is too thick, and, above all, should be as much exposed to the sun as possible, so as to give it colour. So well does it adhere to the tree, that it will brave, without falling, the strongest winds. This Apple should be eaten with its skin on, this having so agreeable a perfume that we can hardly afford to dispense with it. It is largely grown in the United States, and always commands a higher price than any other fancy Apple in the market. In this country it would, doubtless, succeed well under orchard-house culture, on the Paradise stock, or in the open air. Any one having a spare wall might with advantage plant a tree or two of this Apple against it. October is the best month in which to plant.—G.

VEGETABLES.

SEASONABLE NOTES.

Watering.—The common-sense way of doing this in the open air is to pour it on the land between the crops in the evening only, giving sufficient to moisten the soil to the extremities of the roots, and the next morning scattering an inch or so of short manure, rough leaf-mould, old tan, or dry soil over the surface, having previously just loosened it up with the hoe. Where such precautionary measures for lessening evaporation are taken, once a week will be sufficient to water all crops. If watered frequently, liquid manure should be given occasionally, to compensate for the waste of manurial matters in the soil from so much water being so rapidly passed through the upper stratum, to be as rapidly evaporated again by the hot sun the following day. Never use hard pump-water until it has been well exposed to the sun and air, and hoe up the surface two or three times a week. Few seem to realise the benefit derivable from a frequent stirring of the earth's surface in dry weather as a means of retaining moisture in the land and keeping the root-run cool.

The Api or Lady Apple.

Planting-out Broccoli.—The main crop of Broccoli should have been planted out and established in some open situation, and have space enough allowed it to induce a dwarf, sturdy growth, keeping in mind the average growth which each kind usually makes. The Leamington and Eclipse are two excellent late kinds, that will not disappoint if obtained true; they come in in succession as I have set them down. There is yet time to plant them out for a late spring crop; Eclipse will quite meet the earliest Cauliflowers at the end of May or beginning of June, but it should be got out at once to obtain good heads. Early planting usually leads to firm growth, with its consequent immunity from frost in winter. That indispensable kind Autumn Self-protecting should be planted on rich land, as should also the Autumn Giant Cauliflower.

Planting Celery in the Trenches from the Seed-bed.—It is not customary to do this, but in certain places it is not a bad plan; of course, where it is done the seeds should either be sown thinly or the plants thinned out to 2 in. apart in good time before they crowd each other. No doubt transplanting increases the numbers of fibres or feeding roots, and keeps them nearer home, so to speak, than if otherwise treated, and on good land where the food supply—both liquid and solid—is ample, it has a beneficial tendency; but in places where water is scarce and difficult to apply, keeping the roots near the surface is not an unmixed good. We cannot transplant anything without checking its growth, and there are places and seasons when the fewer checks given the better.

Sowing Lettuces for Winter.—From the middle of July to the 25th is a good time to sow a good breadth of Brown Cos, Hick's Hardy Green Cos, Hammersmith, and Tom Thumb Cabbage Lettuces for winter. Select an open situation, where the land is in good heart; if the weather be dry, soak the bed with water before sowing the seeds, and cover with dry soil.

Radishes.—These, at this season, are often difficult to obtain crisp and good, and as the space occupied by them in comparison with other crops is small, we find it best to make up special beds for them, with rich, light soil, on a cool border. The waste soil from the potting-shed comes in well for this and similar purposes, and where many bedding plants are grown the temporary sheltering places used for them may be employed for this purpose; under such treatment they grow rapidly, and are mild in flavour. The French Breakfast Radish is the best variety for sowing in summer.—B. D.

Parsley and Early Horn Carrots.—A good breadth of these sown now will prove to be exceedingly useful, but no time should be lost in getting them in. A south or sheltered border will be the best site for them; it should be dressed with a sprinkling of guano or some other artificial manure, or, if more convenient, the drills may have a good soaking of liquid manure just previous to sowing the seeds. The drills for the Carrots may be 8 in. apart, and as soon as the young plants are up thin them out to 4 in. apart in the rows; this will be sufficient, as the largest may be drawn for use when about the size of one's thumb, and the operation of drawing them fresh from the ground should be continued all through the autumn and winter, merely protecting with a thin covering of dry litter when severe weather sets in. The Parsley drills should be 1 ft. apart, and the young plants should be thinned out to 5 in. or 6 in. asunder. I have a bed that was sown about this time last year that is far superior to any sown in the spring; not a dozen plants have shown any symptoms of running to seed, and they will not do so before next year. Sown now, and some efficient

means of protecting during severe weather, there need be no scarcity of good Parsley.—E. H.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

July 26.—Sowing Wheeler's Imperial and Heartwell Early Marrow Cabbage; also Broad-leaved and Green Curled Endive on a moist border; planting out the last rows of Celery in trenches, in which has been put a good supply of well rotted manure, to which had previously been added soot and salt at the rate of 25 lb. of the former and 1 bushel of the latter to the load; putting Jargonelle Pears in gauze bags to protect them from wasps, &c.; nailing and tying in leading shoots of Peaches and Nectarines; taking lights off early Peach house and well watering the borders; layering Strawberry runners in pieces of turf 4 in. square which have previously been soaked in manure water.

July 27.—Sowing Brown Cos and All the Year Round Lettuce, Red and White Turnip Radishes, and Early Horn Carrots for autumn use; potting Primulas and Cinerarias for supplying cut flowers; storing Shallots and Garlic in a cool shed; earthing up Celery whilst it is perfectly dry; stopping laterals through all Vineries where the fruit is ripening; hoeing, cleaning, and watering amongst late Peas; taking up a border of Early Ash-leaf Kidney Potatoes and laying them in the sun to get green for seed.

July 28.—Sowing Turnips; putting in a few Pelargonium cuttings; staking Chrysanthemums; pruning and nailing Plum trees; pulling up pickling Onions and laying them out to dry; stopping and nailing the shoots of Tomatoes on walls; giving late Vineries a good soaking of guano water.

July 29.—Sowing Mignonette in pots; also Telegraph Cucumbers; renovating linings round all Melon and Cucumber frames; digging ground (previously occupied by Peas) for Cabbages; hoeing among Gooseberries and Currants.

July 30.—Sowing Spinach; also in a pit Osborn's Early Forcing Bean to succeed the outdoor crops; repotting Ferns and Draceenas for dinner-table; earthing up Leeks, thinning Turnips and Spinach.

July 31.—Sowing a bed of Early White Naples Onions for use in spring; pulling up one portion of spring-sown Onions to dry; gathering Gherkins, Cucumbers, Cauliflower, Onions, &c., for mixed pickles.

Flower.

Many annuals, although beautiful while in bloom, are sometimes of short duration. They should (if the seed is not required) be cleared off as soon as their beauty is over, and be immediately replaced by other plants. Attend to the various sorts of plants in the flower-beds as regards training, pegging down, watering, &c., and regulate the growth of standard and pyramidal specimens of Fuchsias, Pelargoniums, Tropæolums, Clematises, &c., while drooping plants in baskets and vases will also require to be occasionally regulated and trained, so as to be made to depend gracefully over the sides and around the margins of the same. Plants suitable for this purpose are the various sorts of Ivy-leaved Pelargoniums, Clematises, Convolvulus, Maurandias, Lophospermums, and many others.

Biennials and perennials raised from seed sown during the spring must on no account be allowed to stand too close on the beds, for if crowded, the whole get drawn up weakly, and a season is so far lost that they flower only meagrely the ensuing spring and summer. In preparing nursery beds for those that do not absolutely require a shaded position, select an open position where they will make close, compact growth, which will enable them to stand the winter and produce double the quantity of flowers that can be obtained from weakly grown examples. Those that do not like full exposure to the sun, as, for instance, Primroses and Polyanthuses, should have a place at the north side of a wall, not, as they are often seen, crammed away under the shade of trees that not only darken them too much, but impoverish the soil to an extent that prevents them attaining anything like the necessary strength and vigour.

Herbaceous Borders.—Stake and tie everything that requires it before it is broken down by the wind, especially tall-growing subjects like Hollyhocks. These fine plants are often thrust at the extreme back of a border, close up to trees or shrubs, where there is no possibility of their ever being more than mere shadows of what they would grow to if justice were done to them; in such places the bottom leaves are usually all destroyed by red spider before their flowering is half over. Mulching with 3 in. of rotten manure over the roots will greatly assist them, and a free use of the syringe with clean water twice a week, taking care to moisten the roots as well, will much improve their health and appearance. Remove all dead and decaying tops from plants that have flowered early, in order to reduce to a minimum the greatest drawback to herbaceous plants; but for the sake of mere appearance never remove the healthy tops from any plant, or the never-failing result will be to weaken it seriously.

Show Pelargoniums that were placed in the open air to ripen their wood, as recently recommended, will now be in a fit state for heading down, an operation which should be performed at once, as their ability to flower early next spring depends much upon the time at which they are cut down. No plant with its roots confined in a pot should have its head removed without first allowing the soil to get as dry as it will bear without injury. It is necessary to be more careful in this matter in the case of Pelargoniums than in that of most plants, as they are more impatient of their roots being in soil that is too wet than the generality of plants in cultivation. After they are headed down place them in a cold pit or ordinary garden frame in a sunny situation, put the lights on, but tilt them in the daytime in order to admit air, closing them in the afternoon whilst the sun is on the glass, syringing them freely overhead at the same time, which will be all the water they will require until they have broken into growth afresh.

Fuchsias.—A portion of the plants that flowered earliest may now with advantage be placed for ten days or so in the open air, during which time they should receive only just enough water to prevent them from flagging. If after this their side branches are cut into four or five joints, the leading shoot being shortened proportionately, and they are then put in a house or pit, where the atmosphere can be kept a little close and moist by freely damping the floor, closing the lights in good time in the afternoon, and syringing overhead, they will quickly throw out fresh shoots that will bloom freely through the autumn; and to assist them to do that they should have weak manure water applied once or twice a week.

Petunias.—These make excellent pot plants and are very showy, especially the flaked varieties, both single and double. To have them stocky and short-jointed they should be grown out-of-doors, fully exposed to the sun, and be stopped frequently to induce them to break back freely and form bushy plants. When grown under glass the stems become drawn, which they likewise do in the greenhouse while producing their blooms. To obviate this as much as possible they should be placed in light airy positions, where they only get a small amount of shade, if any at all. By cutting back any that have become straggling and drawn, and replacing them out in the open air, they soon break again and flower with great freedom, so that a constant supply may be kept up by growing a few plants and treating them in this way. While out-of-doors the pots should be plunged so as to prevent the sun from drying the roots.

Celosias.—The brilliant and feathery plumes of these and the length of time during which they may be had in bloom render them very desirable plants to cultivate, either for the purpose of supplying cut flowers or for greenhouse or conservatory decoration, where for effect they have no equal among soft-wooded plants. Unfortunately, however, they are very subject to red spider, and, unless kept well syringed while growing and freely supplied with water at all times, they become so much injured as to lose their foliage entirely long before the flowers become shabby.

Double Zinnias.—There is generally a scarcity of gay-blooming plants late in autumn, and although Zinnias are not generally cultivated in pots, they are most valuable for that purpose, their gay colours and fine large globular flowers making quite a display indoors long after they cease blooming in open beds, where damp nights and heavy rains generally cut short their beauty. Any left over from planting should have their flower-buds nipped out and be potted up at once, after which set them in the shade for a few days till they get hold of the soil, and then out in an open situation. A few seeds sown now will not be too late, as they grow rapidly at this season and soon come into bloom.

Late-flowering Lilies of the lancifolium section will now have formed their flowers and have filled their pots with roots. Where there are many bulbs in a pot, the soil naturally becomes exhausted, and unless from this time onwards they are regularly supplied with manure water, the bottom leaves will turn yellow and fall off long before the flowering is over, a circumstance which gives them an unsightly appearance. Where a number of these useful decorative plants are grown, their season of blooming may be much prolonged by placing a portion at the north side of a wall now, where they will not receive much sun. When the flowers are visible this will not have any effect upon drawing them up weakly, provided they are set where they will get plenty of light; keep them well tied out so as to admit light to the inside leaves. If aphides make their appearance upon them they should be immediately thoroughly syringed with Tobacco or Quassia water, laying them down on their sides for the purpose, for if the aphides be allowed to remain on them, they will destroy the leaves in a very short time. One of the first essentials of successful Lily culture is to maintain the leaves in a healthy state as long as possible. The number of flowers produced by pot Lilies is generally not more than half the quantity which they would bear were the treatment such as they require.

Violets.—Well-established plants of Violets are now throwing out strong runners, and if a stone be placed on each so as to press them to the soil, good strong plants can soon be obtained. As soon as they have begun to root into the soil the runners should be lifted and planted out in a piece of well-prepared ground in the form of a bed, and they will yield fine flowers early in autumn and winter if the weather be at all open and warm. The state of the weather has much to do with the production of flowers.

Dianthus.—The annual varieties are now getting into full bloom. There is the well-known Indian Pink (Dianthus chinensis) and its double form; both are now in flower, and they contain very charming varieties, especially those having fringed edges. Then there is the pretty dwarf Dianthus Heddewigi and its fringed variety, laciniatus, both large and rich in colour. The best soil for these annual Dianthuses if one of a light sandy nature. The seeds can be sown in the open ground, and the plants thinned out to a requisite distance when the seedlings are large enough to be handled.

Shrubbery.

Where alterations in gardens are contemplated, the present is the most suitable time for making notes and observations having reference to these changes, as all trees, &c., have now attained to a mature condition as regards the hue or colour of their foliage, their habit of growth, &c.; and such notes made now will probably be found to be very useful at a later period of the season when such alterations are being carried out. In selecting trees and shrubs it is necessary to take into consideration their habit of growth and the form they are likely to assume when they are fully developed, and whether they will be of an upright or drooping habit, or of a round-headed or pyramidal form, &c.; and, with a view to secure the desired effect in grouping or arrangement, the hue and form of leaf should also have attention given them. There is also another very important point which should not be lost sight of, viz., that of selecting plants that are likely to thrive in the soil and situation where it is intended they should be planted.

Indoor Fruit.

Vines from which the Grapes have been cut, and that manifest an undesirable tendency to produce wood, stopping, which is the only way to meet the difficulty and induce earlier ripening and resting, must be persisted in. Keep the houses as cool as possible, and the foliage clean and free from insects, which, now that the fruit is used, will be a comparatively easy task, as syringing may now be done whenever it may be thought necessary. If the borders are at all unsatisfactory now is the time to see to them, either as regards the examination of old drains or making new ones, or giving additional soil and top-dressing. Of course suitable weather must be chosen for such work,

as it is very undesirable to be moving soil when it is in a pasty condition, both as regards the Vines and one's own comfort. Give air freely to Grapes colouring, but guard against cold currents, which are oftener the cause of "shanking" than the state of the soil or border, which generally gets the blame, and sometimes perhaps rightly. A severe check of any kind occurring at that critical juncture when the fruit begins to change from the sour to the saccharine state will cause shanking, and perhaps there is no greater cause of that evil than over-cropping; and yet how slow we are to acknowledge the fact, or to rest content with one good bunch rather than two inferior ones shanked. Go over late Grapes prior to colouring, and clip out all small or imperfectly fertilised berries, and if necessary tie up the shoulders of the bunches. All that are intended to hang on the Vines or keep long should be well thinned out, especially towards the middle of the bunches, else in the winter, should one berry crack or go mouldy, the entire bunch will be sure to follow.

Melons.—A minimum bottom-heat of 70°, and the same of top-heat, are indispensable for crops approaching maturity, and air must be given freely whenever the weather is favourable. Keep the soil in a moderate state as regards moisture, and when watering is necessary let it be done thoroughly and always with water of the same temperature as that of the border. To some, the question of a few degrees' difference between the temperature of the water used and that of the border may seem of little moment, but it not unfrequently makes all the difference between a good crop and a bad one; indeed, it is by a combination of so-called little matters that success in most matters is attained. Stop and tie in successional plants, and carefully guard the foliage from injury of every kind, exposing the fruit to light as much as possible. It is not yet too late to plant more Melons if wanted, but they should be got out without further delay.

Outdoor Fruit.

Peaches and Nectarines should be gone over as often as they require it, removing all superabundant and ill-placed shoots. Take care, however, to destroy none that will be required for bearing next year. Want of observation and forethought in this matter is the cause of so many of these trees being deficient in the way of bearing wood in the centre, the fruit being borne almost exclusively near the extremities of the branches, instead of being evenly distributed over the whole surface. Such shoots as are to be retained should now be laid in close to the wall, an operation especially necessary in late localities, where there is a difficulty in getting the wood ripened over each tree; moreover, now and then, see that the fruit is fully exposed to the sun, and where any symptoms of mildew, either on the leaves or fruit, show themselves, dust the tree, or at all events the affected parts, with flour of sulphur. Let the sulphur remain undisturbed for four or five days before it is syringed off. Be assiduous in regularly syringing with water, and also in giving a copious supply to the roots; this is not only necessary to enable the fruit to attain its full size, but also to prepare good wood for another season. Probably half the failures that occur in the cultivation of Peaches and Nectarines, particularly in small gardens, are due to the trees not receiving sufficient attention. With the exception of pruning and nailing, they are, comparatively speaking, often left to take their chance, or they are subjected to a course of alternate care and neglect, which results in a crop of fruit being obtained in such seasons as it is to be met with everywhere, but none at other times. There is also an immense difference in the size and quality of fruit borne by trees that receive the requisite attention as compared with that produced by those existing under neglected conditions.

Apricots.—These should also have sufficient young shoots nailed or tied in close to the wall to supply bearing wood evenly over the whole surface. These young shoots, when in absolute contact with the wall, will frequently set a crop of fruit when that upon spurs, which stands further away, is destroyed by spring frosts. The difference that 2 in. make in such matters would scarcely be credited by those who have not had an opportunity or taken the trouble to compare the results,

Vegetables.

Shallots, Garlic, early Peas, early Cauliflowers, autumn-sown Onions, and the earliest kinds of Potatoes ought to be harvested, and as soon as they are lifted let the ground be cropped as follows: On the Shallot, Garlic, and Onion ground put Lettuces, Endive, Turnips, and Early Horn Carrots; on the Cauliflower ground, winter Spinach; and on the Potato ground, Broccoli or other kinds of winter Greens. If the ground was well treated for the preceding crops, no preparation beyond that of cleaning and levelling will now be necessary. We usually plant the main crop of Broccoli on the Strawberry plot that has done duty for two years. As soon as the fruit has all been gathered, the plants are planed off with spades, and the Broccoli planted between the rows, in holes made with a crowbar, and filled in with fine soil. Under these conditions Broccoli thrives at least as well as on ground that has been elaborately prepared, putting out of the question the saving of labour and time. Small saladings, Mustard, Cress, Radishes, &c., may still be sown in open borders in small quantities weekly, and as French Beans are not likely to do much good outside, provision should be made for making a sowing forthwith either in frames or in pots, to be introduced into houses or pits as room can be found for them.

Tomatoes.—The naturally vigorous habit of these plants is such that they usually grow too rank if they receive over much moisture at the roots, but in exceedingly dry weather they must be regularly supplied with water, or the fruit will neither swell to the requisite size, nor will the plants continue growing. Do not allow them to get too much crowded with superabundant shoots or to hang loosely from the wall, or the progress will be slow. They should be kept regularly and evenly trained, so that the sun can reach every part.

Herbs.—In drying herbs an open shed or room, where plenty of air can be given, is necessary. Stretch out a piece of netting, such as is used for protecting fruit from birds (wire netting if at hand will do); on this lay the herbs (which should be cut when quite dry) thinly. Thus treated, air acts upon them from all sides, and they dry quickly without losing their best properties. When perfectly dry put them loosely in white paper bags, tie them up, and hang them where they will be free from damp. Herbs treated in this way will be found to be but little inferior to such as are fresh cut. Sage should now be propagated by slips, taking off middling-sized branches and inserting them moderately deep in the ground in rows where they are to be grown. If the weather becomes dry give them plenty of water until they are rooted. The advantage of growing Sage from slips or cuttings is that plants so produced have not such a disposition to flower as those raised from seed.

GLASSHOUSES & FRAMES.

COVERING GLASSHOUSE WALLS.

For covering the back or other walls of cool conservatories, the

Camellia, for striking and permanent effect, is unrivalled. I have often thought, when looking at the weedy character of the usual occupants of such walls, what a change would take place in a few years were they planted with a good selection of Camellias. It often happens that, in such positions, only a subdued light reaches the base of the wall, and most of the plants of a climbing or semi-climbing habit rush up to the top after the light, and the lower part of the wall is left bare, or, at least, only thinly covered. The Camellia, when planted out in a good border, will thrive and flower in a position, as regards light, where other plants (except, perhaps, the Myrtle) would only have a lingering existence. Of course, to cover a wall 12 ft. to 15 ft. high with Camellias will take time; but every year they will gradually creep higher and improve in appearance, and when at last the wall is covered and the plants in flower, what a grand display will be the result! Even though scentless, the flowers are so brilliant and varied in colour, from the purest white to the darkest crimson, as to be altogether matchless. I have a Camellia-covered wall in my mind's eye that I had charge of years ago, where flowers could be had in abundance from November till May—and such flowers—not like the small thin-petalled starvelings often seen growing on plants in pots. There is no question, I think, that Camellias planted out in a good border produce the finest flowers, and although the bush form is the natural habit of the plant, yet, if planted out in a young state against a wall, it submits to training as readily as any climbing evergreen; and if early, medium, and late-flowering varieties are selected, flowers in abundance may be obtained from a wall for at least six months in the year, and that, too, at a time when flowers are most valuable. In planting out Camellias, and hard-wooded plants generally, deep planting should especially be guarded against; for in making new borders that will, for the most part, be composed of fibrous materials, decomposition and settling will go on for years, and the plants gradually, but almost imperceptibly, subside. When this takes place the proper remedy is to lift the plants, make up the border, and re-plant, when no harm will follow; but I have met with instances where the borders had been gradually made up with fresh soil without lifting the plants, and the accumulation of soil round their collar brought on a sickly, unhealthy appearance, which was speedily followed by death; and, doubtless, some cause other than the true one was assigned for the disaster. I do not think, as regards soil, there is anything better for Camellias (if permanent effect is aimed at) than a rich turfy, rather sandy loam. If at all adhesive when the fibre in it decays, it will probably become too close and heavy, and although Camellias enjoy abundant supplies of water, still, anything in the shape of stagnation at the roots must be avoided; therefore, if the loam is at all heavy, peat or thoroughly decayed leaf-mould, with a proportion of sand and lumps of charcoal to increase its porosity, should be added; but in using leaf-mould, unless care is used to have none but what is thoroughly decayed, fungus may be introduced amongst the roots that may be productive of serious injury to the plants. I have also on several occasions seen the same result follow the use of peat in which very small particles of the rhizomes of the common Brake Fern, or little bits of the root of the common Heath had been left in the soil. Therefore, for making Camellia borders, if good loam can be obtained which does not contain lime beyond the small average amount usually found in all soils, I should recommend its use in preference to composts of all kinds, and trust to liquid manures, and especially that made from soot, to give strength and vigour when required.

As wall or pillar plants for a cool house Myrtles might be more extensively used than they are; when planted out they grow rapidly, and their sweet white flowers are exceedingly beautiful. Sprays of glossy-leaved sweet-scented Myrtle are very desirable for mixing with cut flowers either in the drawing-room vase or in bouquet making. Habrothamnus fasicularis and elegans are free-growing and free-flowering plants, of semi-climbing habit, well adapted for covering walls, pillars, or arches in a cool conservatory, as is also the Cytisus racemosus, which, when planted in a border of loam, assumes an almost perpetual flowering habit.

Many other plants might be mentioned, such as Magnolia fuscata, which, although of slow growth, makes rather a desirable wall plant, especially for low walls. In a rather dark shady corner, Clianthus puniceus would be at home, as it is rather subject to attacks of red spider when the sun shines full upon it. Abutilon Thompsoni makes a grand wall plant, growing as freely as its parent, the old striatum. I may say, several years ago, I obtained seedlings from this identical with striatum, and so I suppose Thompsoni to be a variegated sport from that old variety. In warm light houses few things can equal the Luculia gratissima for covering walls. The Heliotrope, also, is a good subject for a light position, as, by judicious pruning back, it may be in bloom at any season of the year. I once had a wall covered with it that I always cut back in July to get a new flowering growth for autumn and winter. Fuchsias, also, when planted out and pruned back in July, will make a new growth and bloom beautifully through the autumn and winter months. Fuchsias, however, attain their greatest perfection when trained along the

tie-rods supporting the roof, as then they entirely hide their supports and produce a wondrous wealth of gracefully-drooping floral beauty, that must be seen to be adequately appreciated. Oranges and Lemons—in fact, all the Citrus family—do well in loam and planted against a wall in a warm house, and I have seen good crops of at least useful fruit produced in this way. These should, however, be planted out when young and when the branches are pliable, so as to be easily got into shape without having recourse to strong ligatures, which would have a tendency to check the proper circulation of the sap.

There are various ways of clothing the back walls of Ferneries and stoves with Ferns and fine foliage and creeping plants; and, when so treated, a large collection of plants may be grown in an interesting manner in a comparatively small space. Supposing it is desired to cover a wall—at the back of a Fernery, for instance—in which case I will assume the house to have a span-roof running east and west, the back wall being, perhaps, 6 ft. to 8 ft. high, and, of course, on the north side. I am only supposing this height, as for my purpose it does not matter whether it is more or less. The wall in the hottest part, at least, of the day, would be shaded, and would in consequence be the dampest, shadiest position in the house, eminently suited for flower culture. One mode of planting such a wall would be as follows:—Run parallel wires, tightly strained, 6 in. from the wall and the same distant apart, to form a support for Mosses, Ferns, and soil, which latter should be principally composed of peat, with some charcoal and pieces of freestone intermixed. I think I need scarcely enter into details, as a small amount of ingenuity, when accompanied by taste, will plant the surface of such a wall with Ferns, Club Mosses, &c., so as to produce a charming effect with the surface neatly mossed over. Begonias of the variegated section might also be introduced with Fittonias, Eranthemums, Sonerila margaritacea and S. Hendersoni, Cissus discolor, and Panicum variegatum, but the stove plants, of course, would only be introduced into a tropical Fernery.

Cut-leaved Sow Thistle (Sonchus laciniatus).

Another way of making a Fern wall may be just briefly noticed, and as this will be a more elaborate affair, it will consequently be more expensive. In the first place call in the bricklayer, and have a series of small brick arches run all along the base of the wall. On the first series, run a second just a little narrower, and on the second a third, and so on till the top of the wall is reached, the arches gradually decreasing in size, so as to be narrowest at the top. If the arches are one brick thick, that will be quite strong enough. It is not necessary that the arches in any one series should be all alike, as if diversity of outline is sought for, it may be obtained by varying the size. This system of brick arches will form the base or foundation of the structure, and may be dressed in any shape desired, leaving plenty of pockets to hold soil to grow Ferns and other plants. The mode of dressing and hiding the brick-work is altogether a matter of taste, and may be done either with virgin cork, or spar, or red sandstone, worked up with cement, avoiding as much as possible all formality. Of course all the brick-work will be covered with whatever material it is decided to use, as the main object in using brick arches at all is to make sure of a supply of moisture and soil. I believe a good case might be made out for the extended cultivation of Oranges, Lemons, Guavas, Cape Gooseberries, &c., on the back walls of Vineries and other fruit houses; but in all cases where the walls are used in this way they should be well painted and wired for training, and once a year the plants should be unfastened from the wall, which should be washed with a solution of soft-soap, or some other insecticide, to keep down insects. E. H. D. Y.

Iris persica and reticulata for Winter.—I have found these to do well treated as follows: I put from four to six roots of them in a 5-in. or 6-in. pot in August or September, and plunge them like Hyacinths till they begin to grow; then I put them into a cold pit, giving all the air possible in fine weather, and only keeping them from frost, and just previous to their blooming I bring them into the greenhouse, giving them a good place on a light, airy shelf, where they throw up strong blooms. When out of flower I replace them in the pot, encouraging the foliage so as to keep it green as long as possible. When it shows signs of turning yellow, I gradually withhold water till the soil becomes quite dry, and allow them to remain in the pots till they are wanted to start again. —J. F.

The Star-flower (Triteleia uniflora) as a Pot Plant.—Many may not be aware how well adapted this pretty little spring-flowering bulb is for pot culture. About a dozen good-sized bulbs should be placed in an 8-in. pot, using a compost of leaf-mould and turfy loam, to which may be added a portion of well-decomposed manure; pot firmly, and give a good watering to settle the soil, and then plunge the pots in a cool frame or at the back of a north wall up to their rims. During September and October place them where they may enjoy full exposure to sun and air; they may be wintered in a cold frame where they can be fully protected from hard frosts, taking care to keep them sufficiently moist at the roots to prevent the foliage from becoming yellow, which it is apt to do if they be allowed to remain dry. When the buds begin to appear they may be removed to the conservatory or sitting-room. There is one peculiarity in the growth of this plant which adds much to its beauty when thus grown, viz., the leaves turning downwards and completely clothing the sides of the pot; in order, therefore, to see it to full advantage, it should be placed in a somewhat elevated position. For those who have no convenience for forcing flowers the Triteleia thus treated is invaluable, as the slight protection alone which it receives suffices to bring it into full bloom some weeks earlier than those in the open border.—J. B.

The Cut-leaved Sow Thistle (Sonchus laciniatus) **as a Table Plant.**—The plant in question attains a height of some 2 ft. or 3 ft., or even more, and it should be grown with but a single stem, as in that state its peculiar beauty is displayed to the best advantage. The leaves are long, thin in texture, and pinnate, and their colour is bright green. Under artificial light they appear almost transparent, which, added to their pendent, arching habit, render this Thistle a really charming subject for room decoration. It may be grown in small pots for the convenience of placing it in ornamental vases, and the soil should be loam, peat, and sand, in the proportion of two parts loam to one of peat and sand; the drainage must be perfect, and during the time it is growing water must be freely supplied, but during winter, when at rest, just sufficient to keep it alive is all that is necessary. It will strike tolerably free from cuttings made from the small side shoots, but the stout main shoots will not strike readily. It is a native of the Cape de Verd Islands, and may be grown in a frame or an ordinary greenhouse.

House and Window Gardening.

Window Plants.—From week to week I have read in GARDENING ILLUSTRATED various complaints from amateurs as to the non-flowering of their plants. Perhaps two or three simple rules for their guidance would not be objected to. The first is, daily attention. Every morning spend half an hour looking closely into their wants; see if they have enough of light and air; look well if that pest the greenfly has attacked them, and carefully pick the insects off; examine the under part of the leaves especially. Secondly, do not deluge your plants with water. I have seen poor plants soaked with moisture day after day, even in winter, and the consequence, of course, was they died. Give plenty of air, even in winter, and never keep a plant in darkness. I have been window-gardening for several years, and have reared most beautiful healthy plants, such as zonal and Ivy-leaved Geraniums, Musk, Yellow Broom (Cytisus racemosus), and other plants, which have been admired by those who have been able to buy beautiful specimens, but lost them very soon for want of a little attention. Some people buy lovely plants, and admire them very much, but place them, perhaps, behind a curtain away from the light, and where they rarely get a breath of pure fresh air, and with this treatment their owners expect them to give forth beauty. I have one window facing south, and I have a very cool greenhouse (too cool, I fear) facing the north to keep those plants in that I do not require to adorn my sitting-room. I have not said anything as to soil; I often find it difficult to get all that is required, but I am on the sea-shore, and I use very largely sea-sand. —ERINA.

Keeping Cut Flowers Fresh.—With regard to the length of time during which cut blooms will remain fresh much depends on the manner and at what time they are collected. Flowers should, if possible, never be cut during the heat of the day, but of all things avoid doing so in sunshine, as they droop almost at once, and even if they regain their freshness when placed in water, it lasts but a short time. Flowers should always be cut with a sharp knife, not with a pair of scissors, and the stems should be severed in a slanting direction; the advantage of doing so is that when the little vessels of the stem are cleanly cut, they draw up moisture freely, which keeps the flowers fresh; but if bruised, absorption is stopped, or at least impeded. The water in which flowers are arranged should be changed every alternate day, if not daily, and the stems of the flowers should be cut afresh.—A. H.

Hemlock Leaves and their Uses.—Permit me to direct attention to the usefulness of the leaves of Hemlock for decorative purposes; small leaves of this plant have a pretty light Fern-like appearance when interspersed amongst flowers in a vase. The foli-

age of this plant when growing in dry sunny spots assumes a crimson-brown tint, which for the decoration of light-coloured fruits is very effective.—A.

Panicum variegatum.—Where indoor decoration has to be provided, plants of a trailing or pendulous habit of growth are necessary for furnishing the edges of jardinettes or stands, and this is an invaluable plant for the purpose, its habit of growth and beautiful variegation being in every way perfect. I insert three cuttings in a small pot, and, as soon as they get a few inches long, peg them down close on the soil, when they throw out a number of side shoots and form excellent plants without any further training.—J.

Campanula fragilis.—The old drooping C. fragilis, now seldom met with, is one of the most beautiful long-blooming plants which we have for windows, where its profusely-flowered pendent shoots can be seen to the best advantage, and its colour, pale blue, from its comparative scarcity, makes it still further desirable. It strikes freely from cuttings put in any time during the spring and summer in ordinary soil; small pots 7 in. or 8 in. in diameter are sufficient for even large specimens. The plants will last for a number of years.

Striking Cuttings in Windows.—The cuttings of many plants from roots much better in a room when placed in water than when planted in soil. A phial is filled with water and the cutting inserted in it to the depth of about an inch. Paper is wrapped round the cutting so as to close the mouth of the phial, which is then placed in a sunny window. Should the water evaporate too much, luke-warm water is to be added. Cuttings of such plants as Oleander, which are slow to root, are very successfully treated in this way. When the roots have been developed inside the phial to such a degree that they will not pass through its mouth, the phial is to be broken, and the cutting thus released may then be planted in soil.

Spiræa palmata as a Window Plant.—Many readers will doubtless be glad to know what a valuable plant the Spiræa palmata is for growing in rooms. About three weeks ago I brought a nice plant into the house from the conservatory, just as the trusses were opening, and it is still in full bloom. This species flowers a little later than the Spiræa japonica, but it is much superior to it, as the large branching heads (not spikes) of bright rosy-pink are of such an uncommon shade, and the pale green leaves contrast so beautifully with the flowers. It must, indeed, prove an especial favourite to everyone who grows it and sees it in its full beauty.—W. A. G.

Table Plants.—The genus Dracæna furnishes many plants whose brilliant-coloured foliage and graceful habit render them all that can be desired for table decoration, and they will generally succeed well when grown in soil consisting principally of turfy loam with a portion of peat, leaf-mould, and sand. They may also be rapidly increased by means of cuttings or eyes, as the tops of over tall specimens may be cut off and potted in sandy soil, in 3-in. or 4-in. pots, and placed under a hand-glass in a stove, where they will root in a fortnight or three weeks. Large plants, too, cut down to nearly the surface of the soil will soon produce several young shoots, that can be formed into cuttings, which soon take root, and the stems of plants so cut down may be split down the centre, when each division, cut into pieces of about 1 in. in length, containing an eye or undeveloped bud, will strike if gently pressed into pots or seed-pans filled with a compost formed of sifted leaf-soil and sand plunged in a mild bottom-heat and covered with a hand-glass. Some few of the species will succeed in a greenhouse temperature, but the sorts best adapted to table ornament, such as D. Cooperi, rubra, terminalis, gracilis, and others, require a warmer temperature.

Hardy Purple Clematis (C. Viticella venosa).

Clematis Viticella venosa.—This is one of the hardiest of Clematis, and one of the best for climbing over hedges, low shrubs, &c. Plants of a good size may be grown in tubs or pots, and are excellent for balcony decoration. Its flowers are of a reddish-purple colour and very freely produced. It will grow in any ordinary garden soil provided it is well drained. The best time to plant is in autumn or in spring.

Sweet Peas in Covent Garden.—These are now plentiful in this market; the pure white-flowered forms and the Scarlet Invincible are the kinds liked best, on account of their decided colours. They are the produce of seeds sown in November, a time when many sow their first crops of culinary Peas. As soon as they are above ground they are earthed up and staked. As the weather gets warmer the plants grow apace, and from June onwards they yield a good supply of bloom, which is kept regularly cut three times a week, and the better this is attended to the longer the plants continue to grow and yield blossoms. For later supplies seeds are sown in succession during the spring months, and in dry seasons they are given copious supplies of water.

ANSWERS TO QUERIES.

2509.—**Hoya carnosa.**—The plant in question being pot-bound, shift it at once into the next-sized pot in a compost of half loam and peat, adding thereto a good sprinkling of silver sand. This plant thrives best in a structure where a moist, genial atmosphere prevails. It may be utilised as a climber to cover a back wall, or may be trained round a pillar. It may also be trained about a trellis consisting of a few stout sticks placed round the edge of the pot.—C.

2579.—**Treatment of Auriculas.**—Unless seedling Auriculas are now strong they can hardly be expected to flower next spring, but if good robust plants then they may do so. Pot up at once into 3-in. pots in a mixture of good loam and a little rotten manure and sand. Fix them firmly, and place in a cold frame either on ashes or boards. Shade on hot days, and give all possible air, and keep well watered. A frame that looks to the north and is partly shaded on the south is the best place until the end of September, when the plants may be removed into a greenhouse, or the frame may be put into a warmer position, and the plants replaced in it.—A. D.

2570.—**Balsams for Show.**—If Balsams are in 9-inch pots they should not require any further potting. Such plants would be best now in the open air where they may be kept sturdy and robust. If kept under glass for the next six weeks they must inevitably become drawn. The plants might now have the points pinched out, and be occasionally treated to some stimulant in the shape of liquid manure, that might be increased in strength slightly as the roots fill the pots. All expanding flowers should be pinched off till three weeks prior to the time of the show. If the plants are put under glass about ten days before the show date it should suffice to give the flowers good finish.

2571.—**Window Plants.**—It is most probable that the temperature of the room in which your window plants are kept is in winter

too low, and thus the loss of leaves. Although Fuchsias naturally lose leaves on old plants if the roots get dry, this is, however, no misfortune if the plants be repotted in the spring just as the buds begin to burst into leaf. Geraniums ought not to lose their leaves excepting some of the lower ones, and if they lose all it is too evident that the room gets far too cold, or it may be that if there is in it a fire during the winter that the atmosphere becomes too dry and parched. A regular temperature of about 45° should suit the plants well during the winter.

2517.—**Wireworms in Gardens.**—As fast as portions of the garden become empty, it well be well to fork it up roughly and give a good dressing of soot. Then fork it in and well mix it with the soil. Salt is a good dressing, but this should be applied in the early spring, it is too cold for winter application. It is also a good plan to bury a few inches deep in the soil pieces of Potato, Carrot, Turnip, or other roots and pieces of oil-cake or any soft substance, and lift them occasionally, probably to find them full of worms. Well hardening the soil is also useful, but it is not easy to do with garden crops.

2526.—**Abobra viridiflora,** Canarina campanulata, and Medeola asparagoides.—Abobra viridiflora should be kept quite at rest during the winter in a cool house. When it has fairly started into growth in the spring, and as soon as all danger of frost is past, plant out in the open air in a piece of well-stirred, somewhat light soil, placing some kind of support for the plant to climb upon. Medeola asparagoides is an elegant plant, best suited for basket culture. As soon as the plant shows signs of growth shake away as much of the old soil as possible, and place it in a basket in loam and leaf-mould, well sanded, in equal parts. Hang near the roof in the greenhouse and water carefully. Canarina campanulata may be treated in much the same way, only using a pot instead of a basket, and giving good drainage.—J. C.

2510.—**Arbutus.**—The Arbutus is by no means fastidious with respect to soil, preferring however, a good sound loam. If the natural staple is of a very poor and parching nature, take it out to the depth of 2 ft., mix with the excavated soil a little well-rotted manure, loam, road scrapings, or any good material which may be at hand. Planted in such a compost, the tree will be afforded a good start in life, and will, when it has once attained good root-hold and strength in proportion, take care of itself. In the case of established specimens a mulch of loam and rotten manure would be of advantage. The plant in question has probably suffered from the severity of last winter, and should be cut back at once to the uninjured portions.—J. C.

2524.—**Geraniums not Blooming.**—If your Geraniums are of the ordinary free-flowering kinds, they should, and probably will as the season progresses, flower freely. At the same time, this tribe of plants should not be placed in the shade ; they are children of the sun, enjoying and never flowering so profusely as when subjected to its full influence. Those that are root-bound should either be shifted into the next sized pot, or be top-dressed with some concentrated manure. Up to the present, the season has hardly been favourable to a good display of Geranium bloom in the open air.—J. C. B.

2599.—**Marsh Sundew.**—The Sundews are marsh or bog plants, and when grown artificially the condition of their natural home should be imitated as far as possible. In a bog on a very small scale it is not easy to secure that humidity of atmosphere the plants have at home ; hence the most success is attained by growing them in pots in a cold frame surrounded by or plunged in Moss. The plants should, of course, be planted in peat, that being the most retentive soil, and be kept constantly moist, the pots being placed in saucers of water. I suppose "E. C." is aware of their insect-eating propensities.—E. H.

2585.—**Mushrooms in Passages.**—Mushrooms could readily be grown in the passage leading to an ice well ; but if there was ice preserved in the well at the time, opening the house to get the Mushrooms would waste the ice a good deal. The material employed, short horse dung, should be collected and dried by fermenting in some sheltered place, turning it over twice at weekly intervals. The bed should be made as firm as possible, and be spawned when the heat is between 80° and 90°, with a steady tendency downwards. When the spawn is fairly working, which can be known by the white threads radiating from the lumps of spawn into the manure of the bed, 2 in. of fresh loamy soil should be placed evenly over the bed and made firm with the back of the spade. No water will be required till the bed begins to bear. When exhaustion sets in, tepid water will restore its energies. The bed could be made up at once without drying or fermenting the manure if about one-fifth of fresh loam was mixed with the latter.—E. H.

2588.—**Plum Trees not Bearing.**—If neat, orderly trees are wished for the branches that grow out at right angles from the wall must be pruned back ; in fact, they ought not have been allowed to grow so far, as when the strength of the tree is frittered away in making breast-wood the main branches on the wall must suffer from lack of nourishment ; this is the result invariably. Balance of power in trained trees is a necessity of their existence. "Prune in summer for fruit and in winter for wood" is an old saying, and contains much truth. The fruit will come on last and previous year's wood.

2598.—**Blood and Bone Manure.**—The quantity of any given manure that can be profitably used must depend as much upon the nature of the crop as upon the character of the soil, but in vegetable culture in gardens much more may be given than would be desirable in farm practice. Thus in the case of the manure named from 6 lb., to 8 lb., or even 10 lb., per square rod may be used in special cases. It should either be used in spring when the crops are sown, or else as a top-dressing after the plants are up. Where heavy dressings are given divide into two equal portions, and use one with the planting of the crop, and the other as a top-dressing about May or June.

2527.—**Cape Gooseberries.**—Shift into larger pots if they will require more root room, and as soon as the roots are active again, move to a position near the glass in a cooler house than a Cucumber house, and where the atmosphere is less moist. Keep them well supplied with water and they will bear as soon as they are strong enough in autumn. Pot in turfy loam and manure, two parts of the former to one of the latter.—E. H.

2573.—**Ants in Gardens.**—The total extermination of ants, even if it were desirable, is a difficult matter, but they may be reduced in numbers by trapping them perseveringly, by frequently disturbing their nests, and by scattering guano and other distasteful substances about their runs. Ants are very partial to sweets of all kinds, and this fact may be so employed as to lure them to destruction. They are also fond of raw fresh meat. Where sparrows are too numerous a few may be shot, their breasts laid open with a knife, and their bodies laid in the run most frequented by the ants. The traps must be visited frequently, and the ants destroyed by brushing them into boiling water. Try paraffin oil.

2513.—**Renovating a Garden.**—Can you obtain any clay or stiff loam? if so, cart it on in autumn after the land has been rough dug, and leave it exposed all the winter. In the spring it will crumble down and easily mix with the soil and ashes, and must improve it. Trenching it up 2 ft. deep will mix the ashes with a greater bulk of soil, and therefore improve its staple.—E. H.

2572.—**Forming a New Garden.**—If the land requires draining do it at once, 4 ft. deep, securing a good outfall, so that the water may pass rapidly away. Then decide upon the boundary fence, whether brick wall, wood fence, or hedge shall be used. The only advantage a wall or a wood fence possesses over a good hedge of living plants is its adaptability for the rearing and training of fruit trees against the sides. If economy is an object, it is as well to bear in mind a garden surrounded by a good hedge will be nearly as useful as if walled in. Of course the hedge must be kept well trimmed, whatever it may be composed of. Next it must be decided about the paths—their number, width, and composition. If the garden is of regular outline, then divide it into four equal parts, with intersecting paths from 4 ft. to 5 ft. wide. If it be walled in then a border in proportion to the height of the wall must be left for the wall trees. The best system to adopt for the fruit trees in the open garden is the espalier. Have wires strained where it is intended to plant the trees, and plant and train the trees to them. Bush fruits may either be planted all in one place or in lines by the side of a path or paths. But before a tree is planted the ground should all be trenched up 2 ft. deep, without bringing any bad soil to the top. The garden should first be fenced in, then the paths laid out, and the ground trenched. This work may be done as soon as convenient ; then fix the espaliers, and plant the fruit trees in November. If the garden be laid out at once many crops of autumn and winter vegetables may be got in now or shortly.

2577.—**Figs not Fruiting.**—The Fig tree is making too much wood ; lift and prune the roots in autumn. If the roots could be surrounded by a wall, all the better. At any rate bring the roots near the surface, work in at the same time some fresh loam and old plaster or mortar, making the border firm to keep the roots at home. Prune now, by thinning out the young wood, leaving enough to furnish the space, but no more. The moderately strong short-jointed shoots are the most fruitful. —E. H.

2516.—**Evergreen for Covering Fence.**—The Garrya elliptica when established is a rapid grower, and has grand foliage, and the catkin-like flowers are pretty and striking. The Japanese Privet will also rapidly cover such a fence ; and if something a little better is required, plant a row of Cupressus Lawsoniana 3 ft. apart, and keep them trimmed in according to taste.

2499.—**Propagating Syringas.**—They often throw off suckers that may be taken off the parent plant with roots. Syringas may also be easily increased by layering. The autumn is the best time to perform both these operations.

2498.—**Buddlea globosa.**—By layers ; also by cuttings under a hand-light in free, sandy soil early in autumn in a shady place.—E. H.

2500.—**Flowers for Button-hole.**—All kinds of Pelargoniums, including the Oak-leaf section for the sake of their foliage, Tree Carnations, double Cinerarias, Deutzia gracilis, Abutilon Boule d'Neige, Bouvardias planted out in summer and potted up in September, Cyclamens, Diosma ericoides, for its sweet foliage and neat flowers in spring, Jasminum gracile, Erica autumnalis and Wilmoreana, Lily of the Valley in pots, Heliotrope, Mignonette, Primroses of various kinds.—E. H.

2497.—**Fungus on Lawns.**—Water the places with strong lime and soot water in spring, so as to thoroughly saturate the ground. It may be done now.—E. H.

2501.—**Roses not Blooming.**—The Roses have perhaps been overwatered and the soil is sour. The presence of mildew seems to indicate as much. Aërate the surface by stirring, and syringe the mildewed parts with sulphur and water, or dust flour of sulphur over them. Leave the young wood the full length, and expose it to the full light. Doubtless you will have plenty of flowers in spring.—E. H.

2514.—**Ants and Strawberries.**—It will be difficult to entice the ants from the Strawberries now without you can offer them something still more tempting. They are fond of raw meat, and perhaps that may prove a more tempting bait in a Strawberry bed than treacle. Gather up the baits often and kill the ants. Find the nests if possible and destroy them with boiling water. Dust guano on their runs.—E. H.

2589.—**Fruit Falling from Trees.**—Either the wood must be unripe or the soil must be deficient in lime. The former may arise from deep rooting in an ungenial soil, and the proper remedy is to lift the roots nearer to the surface, adding fresh loam and old mortar to the roots. This treatment will also meet the case of a deficiency of lime in the soil.—E. H.

2519.—**Pruning Currant and Gooseberry Trees.**—Thin out the young shoots on the Currant and Gooseberry bushes now, so as to let in air and sunshine, but do not shorten those left till the leaves fall ; then the unripe points (if any are unripe) may be cut off ; this is the best plan to adopt where plenty of fruit is wished for.—E. H.

2529.—**Grapes not Progressing.**—A little fire will be useful in dull weather, but that is not the cause of the Grapes on one Vine doing so badly, whilst the other in the same house is doing so well. Are the kinds identical? It will not be easy to say what is the matter without seeing them. There is probably something wrong at the roots.

2505.—**Beta Cicla braziliensis.**—It may be sown in drills in the open air in April, and the best coloured plants selected to plant out finally. If the plants are required for conservatory decoration in pots, they should be lifted and potted in good sized pots before they get too large, or they may be grown on in pots from the first. They are plants of easy culture.—E. H.

2445.—**Skeleton Leaves.**—These are prepared by simple maceration, *i.e.*, steeping in water until sufficiently rotted to allow of the skin and soft parts of the leaf being removed from the woody fabric or skeleton of the leaf. Take a soup plate or other flat and deep dish and lay the leaves in it layer upon layer. Cover them quite over with rain water, and let them so remain, occasion-

ally shaking or moving them about, so that all may be equally wetted. Take care to keep them always covered with water; if kept in a warm place they will rot sooner. At the end of three or four months, or perhaps earlier, take a leaf out, lay it on a sheet of blotting paper, and with a small forceps pick off the skin and all soft parts; if they will not separate easily the leaf must be returned to the water for further rotting. When nothing but the skeleton remains, place it to dry between blotting paper; the process requires delicacy of touch, and is not pleasant to the smell.—J. H.

2508.—**To Make Putty.**—Procure 7 lb. of whitening and 1 gill or raw linseed oil; first dry the whitening and make it fine, then divide it into two parts; mix one of the parts with the oil on a flagstone, and use up the other part to make it the proper consistency; beat with a hammer, and work up until it will not stick to the hands.—HEMINGBRO.

2518.—**Plants for Exposed Beds.**—Cotoneasters should do well in exposed beds, and so should the green Euonymus, also the yellow-flowered Mahonia or Berberis aquifolia. The carpet Juniper makes a good mass of green leafage, and so do the most robust forms of Ivy. Any hardy shrub or creeping plant that will give a constant leafage is far preferable to flowers of any sort that only look and are always miserable.

2521.—**Nertera depressa.**—The Nertera depressa must be grown in warmth during the winter, so that it shall blossom and berry early. If the plants are then gently hardened, they will thrive fairly well in the open ground during the summer, but the season must be a warm one. The trouble involved in the culture is usually far beyond the benefits resulting. Probably a change to a temperature too low is the cause of your plant doing badly. It is only experienced growers who do this plant well.—D.

2578.—**Blight on Asters.**—With the application of some guano or Clay's Fertiliser and well hoed into the soil, Asters ought to grow out of the blighted condition in which yours are got. If each plant could be bent into a dish holding a solution of Tobacco-water and soft soap the fly would soon be killed, but the plants should have a good washing either by rain or from the waterpot an hour after this application. If dipping is not possible, then try to wash the underside of the leaves with a brush and the solution.

2580.—**Pansies for Show.**—A thin deal box with sloping top pierced at intervals of 3 in. with holes, beneath which are fixed firmly small tin tubes which will hold water, is the best possible medium in which to exhibit Pansies. When the blooms are placed in, and some soft tissue paper laid over, a gentle pressure may be applied for a short time to flatten out the flowers and make them set well.—A.

2507.—**Plants for a Fern Case.**—No doubt the reason that your Ferns thrive badly is that they are in unsuitable soil. If you were to shake them out and get some nice sweet peat soil with a little turfy loam and leaf soil, mix it well and repot into clean pots, no doubt the plants would improve. The Fern case might be the better for a thorough cleansing. If Ferns will not thrive in such a case, other plants cannot be expected to do so.—A. D.

2520.—**Christmas Roses in Pots.**—A Christmas Rose in a large pot simply needs to be stood out-of-doors on a piece of slate in a shady place and kept well watered. If the roots have become pot-bound, the soil on the top to the depth of 1 in. may be picked out and some fresh put into its place. The plant should be taken into the greenhouse again early in November.—A. D.

2584.—**Disease in Cucumbers.**—The soil is probably too rich, and the atmosphere too close and moist. Ventilate more freely, especially early in the morning, to let out the stagnation that has accumulated during the night. Whenever disease shows itself in the stems, dress with quicklime, covering completely the diseased parts with the lime, renewing it occasionally until the plants are restored to health.—E. H.

2583.—**Apples and Pears for Town Gardens.**—Apples: Manks Codlin, Lord Suffield, Warner's King, Kentish Fillbasket, Cellini, Quarrenden. Pears: Williams' Bon Chrétien, and Louise Bonne of Jersey.—E. H.

2586.—**Carnations and Picotees.**—Six good Carnations are as under:—Sybil, rose flake; Clipper, scarlet flake; Admiral Curzon, scarlet bizarre; G. F. Wilson, purple flake; Riffeman, crimson bizarre; and Sarah Payne, purple bizarre. Six good Picotees;—Leah, Constance Heron, Miss Frowd, Mrs. Allcroft, Empress Eugenie, and Lerlina. Carnations, whether from pipings or layers, should be kept in a greenhouse or frame for the winter, especially if good kinds.—A.

2515.—**Management of a Room Fernery.**—A Fern case where the plants become mouldy shows that more air is wanted, and that the soil is either sour or kept too wet. Perhaps a thorough change of soil, with the case well cleansed, and afterwards more ventilation, would make matters all right in the future. It ought not to be difficult to keep down green fly in a Fern case either by smoking with tobacco or cleansing the plants with a decoction of weak Quassia chips.—D.

2596.—**Sowing Annuals and Perennials.**—It is very doubtful whether, in an exposed position, annuals would stand the winter, and it is now too late to sow any kinds of biennials or hardy perennials; but Foxgloves, Delphiniums, Pentstemon digitalis, Polyanthuses, Pansies, Sweet Williams, and similar things might be tried. If any annuals are sown, let them be Candytuft, Nemophylla, Mignonette, Limnanthes Douglasi, Silene pendula, and Myosotis sylvatica, all of which are fairly hardy.—A.

2525.—**Fern Fronds Withering.**—This Fern being hardy requires plenty of air. Place it out-of-doors at night, and do not water quite so much. Ferns like plenty of moisture at the root, but are impatient of anything like stagnant water round them. Too much moisture and too little fresh air is the cause of the fronds drying off.—J. C.

2512.—**Anthericum variegatum.**—Plant out in a free, open situation. This family of plants thrive best in a free, rather light soil. If the natural staple should be of a heavy, retentive nature, mix with it some river sand, leaf-mould, or wood ashes.—J. C.

2523.—**Rose Tree Dying.**—Many kinds of Roses are unfortunately subject to go off in the manner described, especially when a sunless summer is succeeded by a severe winter. Thousands of plants have died this spring in a like manner. The best way will be to root it up, and plant another tree in its place.—B.

2503.—**Seedling Pomegranates.**—Pot off at once into small pots, in a compost of half fibrous loam and half leaf-mould. Keep them in a frame or greenhouse until the latter end of August, and then place them in the open air until the latter end of September. Winter in a cool house, and shift them in March.—J. C. B.

2600.—**Propagating Carnations.**—*C. C.*—These may be propagated from cuttings or layers in autumn or spring. A frame is best for them, but not absolutely necessary. The best soil in which to strike the cuttings is sifted loam and peat in equal parts, adding plenty of silver sand.

2601.—**Lilium auratum Failing.**—I have a Lilium auratum that went on well till about 18 in. high, when the leaves turned yellowish and curled a little, and the flower-buds were gradually destroyed. What was the reason?—W. J. [Something wrong at the root—too much wet or probably some insect eat the bulbs. Turn it out and see.]

2602.—**Sea Sand for Improving Soil.**—*M. E. O.* Sea sand would certainly be beneficial if applied to damp heavy soil, but if the land is very wet your only course is to drain it.

2603.—**Striking Pelargoniums.**—*F. E.*—These will strike readily at this season in the open air in sandy soil and in a partially shaded situation.

2604.—**Sycamore Tree Leafless.**—*Dalstonian.*—If the tree is almost leafless it must be almost dead, but we could not tell you the reason of its dying unless we knew some particulars as to soil, &c., in which it is planted.

2605.—**Removing Strawberry Roots.**—*A. L. W.*—These may be successfully moved at any time after they have done fruiting. Dig them up and shake the soil from their roots. Prune back some of the longest roots, and plant in deeply dug, well manured soil. Make the ground firm after planting, and see that the plants do not suffer from want of water.

2606.—**Uses of Salt.**—*Enquirer.*—If you sow the salt on the ground some little time previous to cropping, it will be perfectly safe and do much good.

2607.—**Cactus.**—*A. A., Stafford.*—We cannot tell the name of your Cactus from such a description as you give. You would do well to take it out of the pot and remove most of the soil from its roots, and repot it in turfy loam and broken bricks, providing also plenty of drainage. Use a pot just large enough to admit the roots comfortably.

2608.—**Radishes and Lettuces.**—I have a garden in the north suburb of London, and cannot get these vegetables to grow well. The Lettuces will not make hearts.—R. M. P. [Radishes during summer require a rich soil and abundance of water. Lettuces also require a deep rich soil, and seed for summer crops should be sown where they are to remain, thinning the plant out to 12 in. or more apart according to variety grown. Frequent hoeing between the plants is also a great advantage, and the soil must be kept moist.]

2609.—**White Substance on Plant Leaves.**—*R. C. C.*—All we can see the matter with the leaves sent is that they are very dirty. The white substance is caused by water in which chalk exists. The first shower of rain that comes sponge the leaves, and afterwards place them out of doors for an hour, and all your troubles in that direction will disappear.

2610.—**Cucumbers Turning Yellow.**—*T. T.*—Give plenty of air and keep the points of the young growths pinched out one point beyond the fruit.

2611.—**Fuchsias Losing their Buds.**—*T. H.*—Too little air and too little water will cause this; so will too much manure water.

2612.—**Seedling Carnations.**—*H. W. S.*—Carnations raised from seed bought from an ordinary seed shop are almost certain to be variable as to kinds and to time of blooming.

2613.—**Cocoa-nut Fibre in the Garden.**—*Ll. T. J.*—Cocoa-nut fibre spread on the surface of the soil is beneficial to all outdoor crops during summer, inasmuch as it keeps the soil moist. If the land is heavy the fibre may be dug into it in autumn, but if light already the fibre would be better raked off.

2614.—**Verbenas not Blooming.**—*Apis.*—Verbenas bought in the market in boxes are often seedlings, not cuttings, and such plants grow rank and do not flower so freely, or so early as plants raised from cuttings.

2615.—**Lapageria rosea not Growing.**—I have the above-named plant in full bloom and good health, but it has not grown an inch this summer. Will it shoot after blooming? It is well watered and looked after according to the best authorities, but I want it to cover more of my greenhouse roof.—W. W. [The profuse bloom of the plant has doubtless to some extent kept the growth of the plant in check. Cut off the flowers as soon as they show signs of decay, and the plant will doubtless grow freely when it has ceased blooming.]

2616.—**Striking Cuttings of Shrubs, &c.**—Would cuttings of the following put in now under handglasses be likely to grow: Jasminun nudiflorum, Jasminum revolutum, Pyrus japonica, Escallonia macrantha, Garrya elliptica, Lonicera japonica, Weigela rosea, double yellow Wallflower?—W. H. B. [Yes. Put in cuttings of this year's growth, selecting those that have half ripened, *i.e.*, firm wood. Use sandy soil made firm by treading, or with the back of the spade, and insert the cuttings firmly in the soil. Water well and keep close till rooted, then give plenty of air. Sprinkle with a fine rose occasionally. A shady situation is the best

2617.—**Keeping Vegetable Marrows through the Winter.**—*Juan.*—Expose at once a few Marrows to the sun by placing them on bricks or pieces of wood They will then ripen well. Cut them as soon as wet weather sets in in autumn, and place them on a dry, airy shelf in a room. They will then keep for months.

2618.—**Making a New Garden.**—*Mr. N.*—We cannot undertake to forward addresses of our correspondents. Kindly send any answer on the above subject you may think proper for insertion in our columns in order that others may have the benefit of your experience besides the person who asks the question.

2619.—**Pruning Roses.**—I planted a Rose (Maréchal Niel) in the autumn of 1878. In the spring of 1879 I cut it back, and during the summer of that year it made a rod 12 ft. or 13 ft. long. This summer each bud has produced a shoot with a Rose; how are these shoots to be treated?—DEVONIAN. [Fasten the shoots so that the wind will not blow them about. Keep the leaves free from mildew by giving water at the roots; and in spring you may shorten some of the shoots back, and you ought to get a good bloom next summer.]

2620.—**Strawberries for Succession.**—*M. T.*—If you plant the following kinds you can have a succession of good Strawberries from June to September: 1, Vicomtesse Héricart de Thury or Keen's Seedling; 2, President; 3, Sir Charles Napier; 4, Sir Joseph Paxton; 5, Sir Charles Napier; 6, Elton Pine. They come into use in the order named. The last-named should be planted in a shady border.

Rose Cuttings.—*A. A., Stafford.*—See answer 2539, July 10.

Book on the Turnip.—*T. H.*—We know of no book specially devoted to this. There have been several excellent articles on the Turnip in GARDENING lately.

Seedling Viola.—*T. S.*—The flowers sent are excellent.

Books.—*B. N. C.*—There is no book of the description you name.

Names of Plants.—*Triptolemus.*—We cannot name the plant without flowers.——*Erina.*—The Toad Flax (Linaria cymbalaria).——*R. Barber.*—Agrostemma coronaria; it is best treated as an annual, although it is biennial in some soils.——*D. E. F.*—White—Campanula urticifolia; red—Betonica officinalis.——*W. S.*—Hæmanthus Kalbreyeri.——*W. W.*—1, Anagallis tenella; 2, Mesembryanthemum species; 3, Mesembryanthemum cordifolium.——*Sion House.*—Symphoricarpus racemosus.——*H. S. G.*—Adiantum setulosum.——*Mrs M.*—2, Campanula persicifolia flore-pleno; 2, Ruscus aculeatus; 3, Escallonia macrantha.——*Z. X. O.*—We cannot name Pelargoniums; send them to some one who makes a speciality of them.——*G. H. W.*—Abutilon Thompsoni; it will grow freely in a window or greenhouse in any kind of well-drained sandy soil.——*E. B.*—Escallonia macrantha; cuttings taken in August would probably root freely in sandy soil under a handlight in a shady situation.——*P. D., Folkestone.*—1, Begonia Weltoniensis; 2, send better specimen; 3, B. semperflorens; 4, B. metallica; 5, B. nitida; 6, B. Saundersi.——*East Sheen.*—Tarragon.——*S. C. K.*—Apparently Viola gracilis.——*Campanile.*—The leaf sent is that of a Gloxinia, an article on which you will find on our front page, July 17.——*J. Daniel.*—Athyrium Filix-Fœmina cristata.——*Dianthus.*—Campanula glomerata speciosa.——*Omega.*—Limnanthes Douglasi, a well-known hardy annual.——*Wildflowers.*—The large yellow flower, Telekia speciosa; the other Salvia pratensis.——*M. D.*—Funkia subcordata.

QUERIES.

2621.—**Onion Maggots.**—Can any one tell me of a preventive and a cure for this pest? I have tried soot without success.—WELSHMAN.

2622.—**Jessamine not Flowering.**—I have a white Jessamine growing against a south-west wall, but it never flowers. How can I induce it to bloom?—MED.

2623.—**Plants for Heated Conservatory.**—What kinds of plants are best for growing on rockwork in a conservatory? I should like some of the different sorts of Palms, also India-rubber plants and Ferns and Roses for the sides of the conservatory.—M. A. S.

2624.—**Ferns for a Vinery.**—Will any one give me a list of Ferns suitable for growing in a Vinery? and also how they should be treated? The Vinery has a southern aspect.—M. C.

2625.—**Uses of a Frame.**—Will any correspondent give me some information as to how I may best utilise a garden frame which I have lately had made. It is a double light, about 8 ft. frontage by 7 ft. depth. What kind of a bed should I prepare? and what surface soil? I have a small garden 90 ft. by 15 ft., and wish to use the frame for plants as a feeder to the garden.—C. C. W.

2626.—**Potatoes Diseased.**—Can any one suggest the cause of my Potatoes failing? The tops turn brown when nearly full grown and the Potatoes are all diseased. The land is considered good, and Cabbage, Onions, Carrots, and all other things do well in it. This is the third year the Potatoes have failed. We use horse manure which has a lot of sawdust in it.—ALPHA.

2627.—**Best Climbing Roses.**—What are the best Roses for climbing both out-of-doors and in the greenhouse, especially dark coloured ones?—B. N. C.

2628.—**Mildewed Strawberries.**—What causes my Strawberries to become mildewed while ripening? The plants are old and rather thick, but as they are a fine sort and bear well I am unwilling to disturb them unless absolutely necessary. I shall be grateful for any hints.—H. B. C.

2629.—**Vallota purpurea in Windows.**—I had two of these given me three years ago; they were then tiny offsets. I placed them both together in a 4-in. pot; they have now fine, broad, healthy-looking leaves, except that the very outer ones always turn yellow at the tip and gradually die down. They show no sign of bloom, and keep throwing out tiny offsets from the bulbs, which

I take off and plant round the margin of the pot. Some months ago I gave them occasionally, but not regularly, strong liquid manure, but discontinued it, as I thought they did not look so well afterwards. I should be glad if some one would kindly tell me what kind of soil they require and general treatment. I have no frame or greenhouse, only airy windows; aspect, south-west.—A. A., *Stafford.*

2630.—**Propagating Virginian Creepers.**—How can I strike cuttings of Virginian Creeper in pots? and what is the best time and soil?—AUTUMNAL.

2631.—**Cut Roses in Water.**—In Hertfordshire I have repeatedly seen Roses improve and expand after being put in water in specimen glasses to adorn the rooms. With me, in the West Riding, they almost always begin at once to shrink and fail, and seldom last to a second day. The water seems clear, but, being rain water, has, of course, some soot in it. Can any reader suggest the admixture of any chemical or other ingredient that would impart to the water a corrective or stronger sustaining quality?—H. B.

2632.—**Gardening in Town.**—In the midst of the jewellery district of Birmingham, and therefore subject to smoke and acid fumes, I have a nice little patch of land on which I wish to grow plants if possible. The sun shines on half its width the greater part of the day. What plants would be best, both flowering and fine foliaged, also creepers for walls (north and south), also a tree that would grow under such circumstances?—T. J. F.

THE HOUSEHOLD.

STRAWBERRIES.

Strawberry Drops.—Weigh two ounces of Strawberry purée—that is, the thick juice of Strawberries that have been rubbed through a fine hair-sieve with eight ounces of coarsely-sifted white sugar. Stir the mixture over the fire with a wooden spoon till it has become liquid and is on the point of simmering. Take it off the fire, stir it briskly for a few minutes, then let the drops fall slowly out of the pan upon a baking-sheet. When cold, remove them with the point of a sharp knife, and put them in a warm place to dry.

Strawberry Fool.—Take a quart of picked Strawberries, ripe, and finely-flavoured; put them into a saucepan with a quarter of a pound of white sugar; cover them closely, and let them stew gently for ten minutes, stirring the fruit now and again to keep it from burning. Rub it through a fine hair-sieve with a wooden spoon, and when it is cold stir into it as much new milk as will make it of the consistency of custard. Serve quite cold. If cream is not to be had, and a rich dish is required, the yolks of two eggs may be mixed with the milk, and the custard may be stirred over the fire till it is on the point of boiling. Time, ten minutes to boil the fruit. Sufficient for six or seven persons. Probable cost, 1s., made with milk only.

Strawberry Hydropathic Pudding.—Take a basin the size that the pudding should be. Put at the bottom a round piece of stale crumb of bread about the size of a five-shilling piece. Place round this, in an upright position, and about 1 in. apart from one another, fingers of bread, 3 in. or 4 in. long, according to the depth of the basin. Pick some Strawberries, and boil them with a spoonful or two of water and as much sugar as will be required to sweeten them pleasantly until they are reduced to pulp. Put the hot fruit gently into the basin with a spoon, so as to disturb the bread as little as possible; cover the surface of the fruit with little odds and ends of bread cut up into small dice, and press the pudding by putting a plate upon it with a weight on the top. Leave it in a cold place for three or four hours, or all night if convenient. When wanted, remove the weight and the plate, turn the pudding upon a dish, and serve. It will come out in a shape. A little custard or cream served with it will be a great improvement. The pudding derives its name from the fact that, thus made, it is served at one or two hydropathic establishments where the patients are not allowed to partake of pastry. Time, about a quarter of an hour to boil the Strawberries.

Strawberry Ice and Vanilla Ice in One Mould.—Flavour three-quarters of a pint of cream with half a stick of Vanilla by boiling them gently together for a short time; sweeten the cream, mix with it the well-whisked yolks of three eggs, and stir the mixture over a gentle fire till it begins to thicken. Strain it into a bowl. Rub ripe Strawberries through a sieve, and take half-a-pint of the juice. Thoroughly mix with this half-a-pint of syrup at 35°, and freeze the two creams in the usual way. Put an ice-mould in ice for a short time. Place in the middle of it a piece of cardboard, cut so as to fit the mould and to divide it into two equal parts. Put the Vanilla ice at one side of the division, and the Strawberry ice at the other. Draw out the separating cardboard, close the mould, and surround it with ice till it is frozen. When wanted, plunge it into hot water for an instant, turn it upside down on a napkin on a dish, and serve. Sufficient for a quart of ice.

Strawberry Ice Cream.—Pick the hulls off a pound of fresh, ripe, finely-flavoured Strawberries, sprinkle half-a pound of powdered sugar over them, bruise them well with a wooden spoon, and rub them through a fine hair-sieve. Mix with the juice thus obtained a pint of thick cream, the juice of a Lemon, and a few drops of cochineal. Freeze and mould in the usual way.

Strawberry Ice made with Jam.—Although Strawberry ices may be made with jam for convenience, they will not equal in flavour those made with fresh fruit. Take half-a-pound of Strawberry jam; mix with it a pint of cream, or milk and cream mixed, and the strained juice of a Lemon. Rub the mixture through a fine sieve into the freezing-pot, and freeze in the usual way. Put it into a mould, set it again in ice, and let it remain until wanted.

Strawberry Isinglass Jelly.—Pick a quart of ripe red Strawberries, put them into a bowl, and pour upon them a clear syrup made by boiling three-quarters of a pound of refined sugar with a pint of water for a quarter of an hour. Cover the dish, and leave the fruit to soak all night. Put two ounces and a half of isinglass into a saucepan with a pint of water which has been beaten up with half the white of an egg. Stir the mixture, and heat it gently till the isinglass is dissolved, carefully removing the scum till it ceases to rise. Strain the liquor through three or four folds of muslin, and when it is lukewarm, mix with it the syrup which has been drained from the Strawberries, half a teacupful of Red Currant juice, and the strained juice of a fresh Lemon. Mix the ingredients thoroughly, put the jelly into a damp mould, and set it in a cool place or upon ice till it is set. If preferred, gelatine may be substituted for the isinglass, and the jelly will then be less expensive. The appearance of the mould will be improved if two or three spoonfuls of jelly are first poured into the mould, allowed to stiffen, then ornamented with large ripe Strawberries, and the mould filled with jelly and Strawberries alternately. Time, eight or nine hours to set the jelly. Sufficient for two moderate-sized moulds.

POULTRY.

Eggs Hatched During the Dog Days.—It is perfectly true that chickens hatched in July and August rarely if ever thrive so well or make such fine birds as those hatched earlier in the year, and for the following reasons: these late-hatched birds get into the scorching sun, which seems to parch their tender skins and prevents the feathers growing so quickly as they should do; then, being hatched so late, they are not half grown when the cold autumn and winter nights come on, and so are unable to withstand the severity of the winter, and many of them die.

Keeping Poultry in Rooms.—It is utterly impossible to keep poultry indoors; they may exist for a short time, but eventually they would die. The natural habit of fowls is to live in the open air, roosting at night and in all weathers among the lower branches of trees, and with the early break of morning to go off hunting for their food. Man has made many alterations in the shape and markings of the different varieties, but he has never succeeded in producing a variety which will live for any great length of time indoors.

Cockerels' Combs.—The comb has nothing whatever to do with the useful properties of the birds. Some varieties, like the Hamburgh, Dorking, &c., have double or rose combs, but these are common to the variety. Of course if pure-bred stock are kept with the idea of exhibiting them, then they must possess the points of the variety; but for breeding purposes, merely for supplying eggs, and for killing, a single-combed cockerel is just as good as one with a double comb.

Cramp in Chickens.—Cramp is generally brought on in chickens by want of sufficient exercise. Birds that have plenty of room to run about at all times never suffer from cramp. We therefore say let them have as much air and exercise as they will take, and they will be free from cramp.

Dropsy in Fowls.—We never heard of fowls suffering from dropsy. Chickens sometimes have little air bladders between the flesh and skin, but these soon disperse on being pricked with a needle, and the chickens are none the worse after the operation.

Pullets Laying Early.—We fancy you must be mistaken in the age of the birds for pullets to be laying when only three months old. We must say it is hardly possible.

HOME PETS.

Worms in Dogs.—The following remedy was used for several years in Brazil, and always effected a complete cure in a Newfoundland, fox terrier, and other dogs: Melt half a pound of mutton suet and one or two ounces of turpentine; when well mixed add two tablespoonfuls of ground glass. Stir until the mixture is cold, or the glass will sink to the bottom. The glass must be crushed and sifted to the finest powder. The dose is a pill varying in size from a Walnut to a large Pea. One should be given every morning for a fortnight to the animal fasting. These proportions will make a large quantity of worm medicine, but even in the Tropics it retained its virtues for a very long time. Sometimes it is necessary to damp the palms of the hands to be enabled to form a smooth pill. A few spoonfuls of milk in which some fresh Mint leaves had been crushed was once given to a motherless pup a month old with very good results.—DONNA DA CASA.

Canaries Unhealthy.—I think E. Underwood has not read the instructions I gave in GARDENING some time back respecting the ailments of our cage pets, or he would, without doubt, have recognised the disease his hen canary is suffering from. Read the back numbers of GARDENING, and you ought to succeed in improving the health of your pets. I should certainly give them a greater variety of seed. Rape and canary seed are hardly sufficient for birds nesting. It will be useless trying to breed with success with birds out of health; therefore give the invalids a rest for a short time. This answer will apply equally to S. Turner. The failure of his success is due to the birds being in ill-health.—A. D'A.

Keeping a Cuckoo.—I caught a young cuckoo in the garden a few weeks ago and placed it in a cage, and it has been regularly fed by a small bird which we call a flycatcher. When the little bird gives up feeding it, how must I keep it? What sort of food must I give it? I should like to keep it alive if possible. Will any one give me a little advice on the matter?—H. T.

Swelling on Bullfinch.—I have a bullfinch which has always refused to wash; its feet have consequently become unhealthy, and are covered with hard horny lumps. Can any one suggest a safe means of removing these?—A. H. L.

Parrots Talking.—Young parrots learn to talk more readily than when old. Place the bird in a room away from noise or disturbance that might otherwise engage its attention, and then for a short time repeat to it, clearly and distinctly, a word or two at a time. Success will follow care and attention in a very short time. —HARRY MOULTON.

Training Love Birds.—Kindness and constant care and attention will alone do this.—HARRY MOULTON.

BEES.

To Make Bees Pay.—I see advice given to begin bee-keeping with a bar-frame hive. I should say, get a good straw hive about 14 in. or 15 in. wide at bottom, and 8 in. or 9 in. high, with a flat top and a hole in the centre about 1½ in. in diameter, to be closed with a cork until required. Have a straw super hive to go on the top. If the bees increase and seem likely to swarm, take the cork out of the hole, and see if they will go into the super. The centre hole is also useful to feed the bees in spring and autumn from a bottle with syrup turned upside-down. After the beginner has got used to handle bees, he can then try a bar-frame; but, speaking from some years' experience, the only way to make bees pay is to feed them well (if required) in September and October and again in March, but not in winter, to get honey in supers or early swarms. Last year in this part of the country, and I suspect most places, bees were a dead loss, but I have kept three good hives through the winter, and have already had two swarms from one of them; I have been offered twenty shillings for the second swarm, and I expect this year to make up for last. Do not let beginners buy a lot of fads, but first learn with a plain hive, and remember that if we take their food from them we must give them plenty in return if we want to make them pay; if possible, see some one actually drive them, put the feeding glasses on, &c. All the grand hives are nice to look at and in theory, but do not pay. With the exception of the bees, the price of which of course varies, he may get all he wants for five shillings, and make a stand out of an old box, taking care to have the inside at least 15 in. about the hive to allow supers, &c., to be put on, and the sides sloping to allow rain to run off, Bees will stand severe cold better than damp, according to my EXPERIENCE.

Food for Bees.—Allow me to differ from the writer who recommends 2 pounds of lump sugar to 1 pint of water "just allowed to boil," as food for bees. At the present season for comb building it is unobjectionable, but for autumn feeding, for storing for the winter, it would be unsuitable from its tendency to crystalise, in which form it would be useless as food. The addition of a tablespoonful of vinegar, a pinch of salt, and furious boiling for a quarter of an hour is necessary to form a syrup which will not crystalise.—APIS.

FERNS ON TREE STUMPS.

MANY Ferns require a support of some kind, especially those having creeping stems or rhizomes, and in no more effective way can the support be given them than by the means shown in our illustration. This represents a Fern introduced a few years ago by Mr. Williams, of the Victoria Nurseries, Holloway, under the name of Niphobolus heteractis, climbing over a dead stump of a Tree Fern, a way in which it makes a very effective object. Stumps of dead Tree Ferns may not be everywhere obtainable, but there would probably be little difficulty in getting them from any nurseryman who imports Tree Ferns largely. Where, however, such material is not obtainable, a good substitute may be found in pieces of Moss-covered Apple or other trees. This should be planted firmly in a pot, as should also the Fern if a trailing one, such as is the plant shown in our engraving. Good drainage must be provided, and also good turfy loam and peat in equal parts, with plenty of sand added. The tree stump must be kept constantly moist by use of the syringe, and the Fern will then train itself round it without any further trouble. Where a large greenhouse exists in which there is convenience for planting a large tree stump in the border, better results may of course be obtained than could be hoped for when pots are used. As well as trailing Ferns, nearly any small-growing Ferns may be used, such as the Maidenhairs, Pteris, &c. In this case the best way would be to get some fresh Moss and bind round the stem of the tree with wire, which could be fastened to a few flat-headed nails driven into the stump. The Ferns may then be planted among the Moss, or a little Fern seed might be scattered all over it. On the top a plant of the graceful Nephrolepis exaltata would grow admirably, and give a finish to the whole. A shady situation must be chosen, and plenty of moisture must be supplied in order to get the plants to thrive luxuriantly and form perfect pillars of Ferns. The temperature of the house in which they are grown must be in accordance with the kinds of Ferns used. Many Ferns will grow well in an unheated house, whilst others require the temperature of a stove. Such arrangements as those suggested need not be alone confined to glasshouses, for similar ornaments may be with little difficulty secured in any light shady window of a room where gas and dust and smoke are not too overpowering, only of course in this case on a small scale. Even in the open air, too, pillars of the smaller-growing hardy British Ferns might be obtained, provided a moist shady situation can be given them. In the areas and back gardens of London and other towns our native Ferns succeed amazingly, always provided they are washed with the syringe frequently, and are planted in sandy vegetable mould, and are provided with sufficient drainage, to prevent the soil from becoming sodden and sour, and plenty of water. Ferns of all kinds in a small state may now be had at such a trifling cost that no one need be without them.

A CLIMBING FERN (NIPHOBOLUS HETERACTIS) ON A TREE FERN STUMP.

VEGETABLES.

AUTUMN AND WINTER CUCUMBERS.

FOR late autumn and winter bearing, sow now one or more of the following varieties of Cucumbers, viz., Telegraph, Masters' Prolific, and Munro's Duke of Edinburgh. The last-named is a great bearer, but the Telegraph produces the longest and handsomest fruit. Plant each seed in a 3-in. pot in a compost of rich turfy loam and leaf-mould in equal proportions, and plunge the pots in some close pit or frame near the glass. An old nearly-spent hotbed turned over and freshened up will be a suitable place, as it is not necessary to hurry them, but it is important to have strong, vigorous plants grown without any kind of check. It is well also to raise a few more plants than will be required, as in that case one has the chance of selecting strong plants only, and in any given number raised there will always be a small percentage of weakly ones. In growing early and late Cucumbers there should be a thorough command over the heating power, especially the bottom-heat, and as regards the latter 75° should not be much exceeded if steady and continuous bearing be desired. Where the autumn and winter supply has to be obtained from one house, leave three plants—one in the middle and one at either end—altogether uncropped through the autumn by pinching off all fruits as soon as they show themselves, and keeping the growth pinched back moderately close at the same time. The advantages of this plan will be seen when about Christmas the exhausted plants are pulled up, giving those left room for development. Cucumbers do not require a great depth of soil in which to start—from 9 in. to 12 in. will be ample; but what they do require is a slight top-dressing at least once a week. They require a good deal of moisture both at the root and in the atmosphere; and frequent top-dressing not only supplies fresh food to the roots in small quantities as required, but it freshens up, and, by preventing stagnation, purifies the atmosphere of the house at a time of the year when much ventilation cannot be given without too great a sacrifice of heat. Where good loam can be had, full of fibre and free from wireworms, it should always form the main bulk of the compost used, adding soot or any other stimulating substance to enrich it where necessary, bearing in mind that although light, rich soils may produce rapid growth at first, yet when the pinch comes the plants often fail, while others grown more slowly in heavier soil will have continued bearing freely, and have furnished fruit in a satisfactory manner. E.

SEASONABLE NOTES.

Endive.—This is indispensable for autumn and winter salads; the early-sown plants quickly bolting and thus becoming useless, a good breadth should be sown now in some open situation. The land need not be freshly manured for this crop, unless it be very poor. Sow in drills 1 ft. apart and 1 in. deep; thin out betimes, and transplant the thinnings if required, allowing each plant at least 1 square ft. of space. Sow again about August 10, and plant out when ready on a dry, warm border. The French Moss-curled and Large-leaved Batavian are two useful varieties.

Spring Cabbages.—Early Marrow Hartwell is well adapted for present sowing, as are also Atkins' Matchless, Enfield Market, and Wheeler's Cocoa-nut; three or four good kinds are better than a greater number. In the midland and northern counties the seeds should be sown at once, but there is no hurry for a week or so in localities situated to the south of London.

Globe Artichokes.—As fast as the heads are cut remove the stems. If the heads be thinned out, those that remain will be finer and better. A thorough soaking of liquid manure will help greatly to swell off the late ones.

Liquid Manure for Melons and Cucumbers.—Tie up a bushel of soot in an old guano bag, place it in a 50-gallon tub or barrel with 3 lb. or 4 lb. of guano, fill up with soft or pond water, stir it up well with an old birch broom, and throw in a lump of lime to clarify it. When using dilute it with an equal quantity of pond water, and use regularly when required. Soot has a wonderfully invigorating effect upon the foliage, and good substantial foliage is essential to the production of well-flavoured fruit. Red spider seems to fight shy of such foliage when grown without shade and in a well-ventilated atmosphere.

Tomatoes.—Keep the growth thin to give the fruit a chance to ripen. All young shoots that spring from the main stems should be pinched or cut off to throw all the strength of the plants into the main crop, as the fruit on the lateral growths will stand a poor chance of ripening. Stop all fruiting branches one joint beyond the cluster of blossoms, and do all tying or training betimes.

Close Cropping.—Vacant plots need not remain uncropped longer than is necessary for the completion of manuring and cultivating operations. Land does not need rest if well managed, and the more it is surface-stirred and cultivated the better for the succeeding crops. Plants derive a good deal of their sustenance from the atmosphere, and a green crop, if not required for use, will, if dug in, return more to the land than it takes from it.

Open-air Mushroom Beds.—Collect some short stable manure and place it under cover till enough has accumulated to form a bed; do not allow it to heat violently; to every five or six barrowfuls of manure add a barrowful of fresh loamy soil, turning it and mixing all together. If convenient the bed may be made in a turf pit or in a deep, old-fashioned frame. A somewhat shaded position will be better for the first bed; build up the beds as firmly as possible, and spawn as soon as the temperature of the bed falls to 85°. If the beds or ridges be altogether in the open air, they should be at least 2 ft. thick at the apex of the ridge.

Gathering, &c.—Gather all Peas and Beans as soon as they become fit for use, but at the same time avoid injuring the plants; this, and securing a robust growth by thin planting, is the only way to secure a succession of pods from the same plants.

Spinach Culture.—A small bed of autumn-sown Spinach will supply a quantity of dishes throughout the spring, at a time when a change of vegetables becomes desirable. Sow the prickly-seeded variety the last week in August, or in early situations the first week in September; the earlier it is sown the sooner will it run to seed the following season. I generally sow Spinach after early Potatoes, without any special preparation beyond raking the surface evenly and smoothly. Sow the seeds thinly in drills 1½ in. deep and 1 ft. apart, and thin out the young plants to 4 in. apart; the surface of course must be often stirred with the hoe to maintain the soil in a healthy condition, but I need scarcely mention that this should never be done when the land is wet. In gathering the produce for a certain period pick off the largest leaves only, but when the plants begin to run in spring the best plan is to cut off the whole tops of the plants down to within 1 in. or 2 in. of the ground; a new growth will then take its place, that may, when sufficiently large, be served in the same way, until finally the roots are exhausted, when of course the remains should be cleared off and the land well manured and cultivated for the succeeding crop. It is the natural tendency of every plant in spring and early summer to throw up flowers and produce seed, but it is far better to divert the strength of all culinary plants that are esteemed for their leaves only into the production of young succulent growth, especially as this not only tends to increase the bulk, but also extends the season of bearing of the crop. Summer Spinach is in a general way not a profitable crop for a small garden. Where it is desired, however, it may be used as a catch crop between rows of Peas, but unless the soil is deep and moist, Spinach in summer will bolt almost as soon as it is fit for use. In special cases where a succession of Spinach is required through the summer the New Zealand Spinach will be found to give satisfaction. Select a warm site and prepare hills as for Ridge Cucumbers; plant half-a-dozen seeds in April round the top of each hill, and if all of them grow thin out to three, of course leaving the strongest. This Spinach is commonly sown in heat in small pots and planted out in May, but it will grow just as well out-of-doors, only it does not come into use quite so early. Hundreds of young plants generally come up in the beds where it grew the previous year, but they will not transplant well on account of the paucity and length of their roots. New Zealand Spinach will continue bearing till the frost cuts it off in October.

Winter Broccoli. — A good winter Broccoli is invaluable where a continuous supply of vegetables is required; for, although where efficient means of protection are at hand Cauliflowers or Snow's Broccoli may be had in good condition up to Christmas, there is still a long interval before the so-called early spring kinds can be relied on to come into use. The kind named Self-protecting Autumn Broccoli is a most useful addition to our list of early winter vegetables, for if planted in succession it continues to produce heads from November onwards. I have just planted a large quarter of this and Snow's after Early Peas. I do not dig, but merely level the ground and draw deep drills 2 ft. 6 in. apart, making the holes with a crowbar 2 ft. asunder in the rows; strong plants are then inserted with the roots a good depth in the ground, and one good soaking of water starts them into active growth. They do not suffer from drought in solid ground nearly so much as in loosely-dug soil, as the evaporation is reduced to a minimum; the growth is also more solid and robust, and better calculated to withstand sudden variations of temperature. I also make later plantings in a similar manner, but in smaller quantities, as in mild autumns they continue to grow very late; in fact, Snow's Broccoli has oftener come in too soon than too late; but in cold weather Broccoli heads may be kept in good preservation by laying and covering with Fern fronds or litter, which I consider preferable to lifting and storing in pits or houses, as a confined atmosphere soon deteriorates the flavour.—J. H.

Treatment of Old Cabbage Beds.—In very many gardens the old Cabbage stems are allowed to remain for the sake of the second crop of little hearts they produce in autumn. The soil amongst them should now be well scarified, and if a top-dressing of manure of some kind can be given the produce will be equal to early spring Cabbages in flavour and tenderness. Where no attention is given to them they are tough and leathery, unless the land be deep and rich.

Best Peas.—Having recently observed a few opinions expressed in this journal anent the relative quality and productivenes of Peas, I beg to say that, of the many varieties I have of late years grown (the seed being invariably obtained from first-class houses), none has equalled Vanguard and Dr. McLean, the haulm of these—the former especially—being literally covered from top to bottom with long handsome pods which are well filled with large juicy Peas of exquisite flavour. As these varieties are moderately early and only attain a height of 3 ft. or 4 ft., they are especially suitable for small gardens.—NORTHANTS.

MESSRS. HOOPER & Co., Covent Garden, London, W.C., request us to state that four heads of their Covent Garden Mammoth Cauliflower, weighing respectively 7¾ lb., 10½ lb., 12 lb., 9½ lb., the result of ordinary good culture, are on view at their shop in the Central Avenue. Such heads of Cauliflower they think have never before been seen.

Catching Slugs and Caterpillars.—Much has been written lately about the usefulness of Orange-peel for trapping slugs. I find slices of Turnip or Carrot far better and to last longer.—M. W.

Wireworms in Soil.—If the soil is soaked with one part ammonical liquor from gasworks and nine parts water, it will not be troubled with wireworms or anything else for a while. It is a good clearer of lawns also, and a good fertiliser. It may be put on land prepared for almost anything. When Potatoes are well out of the ground, a good soaking along the drills will clear the wireworm, and give an improved crop. The mineral oil and water will not cure American bug—even if often applied—unless it is brushed in. I prefer a strong solution of soft soap rubbed in parts affected

with a hard brush. The trees like it, and the bark heals and begins to grow.—One who has Suffered.

FRUIT.

Fruit Crops.—Having more than one string to one's bow this season was but the other day well illustrated by a market grower, who, pointing to a long border of red Moss Roses, said, "These will give me a better return this year than several acres of fruit;" of which, it must be admitted, the crop is not abundant. A few kinds of Apples, such as Julien and the Keswick Codlin, are fairly good; but the larger portion of the trees have only a sprinkling. One of the best crops I have seen is on three ten-year-old trees in my own ground, consisting of a sort too little known, viz., the Norfolk Bearer. In this case the Apples hang on the branches like ropes of Onions, the fruit already colouring, but it is a late keeper and excellent in flavour. Pears are a poor crop; the Hessle is almost the only kind that is bearing fruit and does not show traces of the frost. The same grower who has the Moss Roses has another string to his bow in a few dozen good standard Morello Cherries literally laden with fruit. There is no fear of the market being glutted with this kind, or perhaps any other Cherry this year, and therefore he is sure of a good return for them. Why do not growers plant more Morellos? They yield more crops on the average than any other standard fruit tree grown. There will be an abundance of Plums of all kinds on standard trees presently, the best crops being the Prince of Wales, Diamond, Victoria, and Green Gage. There should be plenty of preserve made from this most delicious of all Plums this year. That most excellent kind, the Farleigh Prolific or Crittenden Damson, is now being planted more freely. This is amongst Plums what the Morello is amongst Cherries.—A. D.

Figs in the Open Air.—This is the time of year for laying the foundation for a good crop next year by keeping the shoots thin and well exposed. Well-ripened wood will pass through a severe winter with only a slight protection where soft immature shoots would be killed. All young fruits now showing should be pinched off before they get to any size, as they can never become useful, and only tend to exhaust the trees. Figs in the midland counties usually make more wood than they do in the south; therefore more attention must be given to summer pruning, and it may in some situations be occasionally necessary—unless the roots are growing in some circumscribed position—to lift and shorten their points. Rigid training is not necessary as regards fruitfulness, and in some instances it may have quite a contrary effect, but in many gardens neatness and order are essential requisites; therefore Fig trees against walls or buildings have to submit to training whether it suits them or not; if the shoots be kept thin and laid in close to the walls, the extra warmth radiated from the bricks will help to ripen the wood. It is in cases in which the shoots are laid in so thickly that every inch of surface is densely covered with foliage that failure occurs. It would be far better to leave trees altogether untrained than to train the branches so thickly that neither air nor sunshine can have fair play. The Brown Turkey and White Marseilles are two of the best varieties.—H. H.

Currants.—Wherever Red Currants are grown the superior character of the Raby Castle over the old Red kind is very manifest. As a rule, Red Currants are but a moderate crop, but the former has by far the best crop and the finest fruit. It is rather later in blooming than the old kind, and to that fact without doubt does it owe this year some of its present fruitfulness. Those who have not this fine Currant should make a note of it. Black Currants are this year getting a comparative rest. Perhaps it is well that the bushes should do so sometimes, for they bear good crops almost invariably. What fruit hangs on the bushes will not pay for the gathering, except the return be an extraordinary one. Next year without doubt there will be a grand crop, and then it may compensate for some other failures. Neither in fruits nor in vegetables should a grower be too dependent upon one kind. If one thing fails another is almost certain to furnish a paying crop.

Raspberries.—This year these are good, perhaps never finer. Last season the suckers made excellent growth, and now the canes are stout and abundantly fruited. Next to Strawberries, the Raspberry is the most difficult fruit to market if the weather be bad, but in a fine season it will always command good prices. Rarely does the Raspberry miss a crop, and, once established in good deep soil, the after cultivation is neither troublesome nor expensive.

Raspberry Arches.—We grow a variety of Raspberry called the Prince of Wales that, in addition to being a good bearer and furnishing fine fruit, produces extremely fine canes. As they were trained to an ordinary stout wire trellis 4 ft. 6 in. high, we should, if pruned down to the trellis, have cut off half the length of well-ripened canes that were mostly 10 ft. high, so for a trial we tied the tops down into arches by bringing the first rod down to the fourth, and so on throughout the piece; and, by tying every rod where they crossed each other, an immovable hedge was formed that has stood the strongest gales, and at present all the upper portion is a complete mass of fruit branches, and the young growths coming up from the base have a far better chance of maturing than when the fruiting wood is cut down low. I can strongly recommend the Prince of Wales as a vigorous good variety that, under the same conditions under which some kinds come so weakly as to be hardly worth growing, will be found to produce a full crop.—J. G.

THE SHRUBBERY.

HEDGES.

Evergreen Hedges, such as Holly, Yew, Laurel, Privet, or anything that is kept cut into a formal shape, and that have attained the full size to which they are required to grow, should be clipped during this month; there is no better time than the present for carrying out such an operation; where this work is delayed until near the close of the year and a severe frost ensues, the shoots are frequently killed back for some distance beyond where cut. In the case of any hedges of this description that are to be so far reduced in size as to necessitate cutting back into the strong wood that has become destitute of leaves, the work should not be done until spring, as the roots would be thereby seriously affected at this season of the year, and whatever little growth was made after this time would be so soft as to be unable to live through the winter; in like manner young evergreen hedges should not be cut until spring further than shortening back with the knife any over-strong shoots that are taking too much lead. Young hedges of this description should by all means be kept wide at the bottom and gradually reduced up to the top, which should be kept quite narrow. The old-fashioned form of hedge, with its perpendicular sides and square or rounded top, finds more favour with some on account of its general appearance, but there is no hedge (if we except Beech) that will ever retain its full strength in the lower branches where most needed when cut in this way.

Deciduous Hedges in and around gardens where it is desirable to keep up an orderly, trim appearance, and which have attained the full size required, may now be clipped. Young thriving hedges that are not yet fully developed should on no account be cut until after the leaves have fallen, as the removal of the shoots of anything of a deciduous habit whilst the leaves are upon them has a most weakening influence, and has a far more disastrous effect upon the plants than the cutting away of the same shoots after the leaves have fallen. Some amateurs are so desirous of keeping everything so close and formal, as to be induced to cut Thorn hedges twice in the year, that is, just before midsummer, and again in the autumn or winter; but it must be borne in mind that, except in the case of the most vigorous examples of this kind of fence grown under the most favourable conditions of soil and situation, this continual clipping, from its exhaustive tendency, will in the end permanently injure the hedge.

Box Edging.—Where this was not clipped in the spring it should now be done. There is nothing equals this edging in appearance when it is not allowed to get too large, and from its natural slow habit of growth, with ordinary care in cutting, many years will elapse from the time of planting before this occurs. When it has once attained sufficient size, like a well-managed hedge, it should annually be cut back to the same point to which it had been previously clipped; by being so treated at first sight it might be supposed that it would have for a time after cutting a bare look, through the old leaves in the course of time falling off; but this does not occur, as when cut close the old stems keep breaking out lower down, and are always furnished with fresh green leaves.

Irish Yews.—When the plants have grown to the size which one wishes them to do, and before they show signs of opening out, let a stout wire ring or two down on the plant over the top, about the same girth as the plant. These rings can be worked in amongst and hid by the small branches. Such appliances will keep the plants perfect pillars for years.—T. W.

Weigelas and their Culture.—These are very hardy, of quick growth, and easily managed. We have many plants of the different kinds, some of the largest being as much as 10 ft. high and 20 yds. in circumference. They have lately been one mass of lovely blossoms, and all who saw them were much pleased with their beauty. Few flowering shrubs are so well worthy of a place in pleasure grounds. They are seen to the best advantage when dotted here and there about the margin of groups of other kinds of bushes; and an isolated specimen here and there on the lawn has a good effect, while none of them are out of place when planted judiciously about the edges of carriage drives and woods. They all lose their leaves in the winter; but then, or when they are in leaf or bloom, they never appear formal, as the loose, half-drooping habit of the branches is very graceful. We propagate them readily by means of division in winter, that is, by lifting the side sucker-like growths with a piece of root attached to them, and planting them by themselves. Another way is to peg down and layer the branches. With us they grow freely in various kinds of soil, from a heavy clay to a light sandy loam. Some of our plants are growing in the most exposed situations, and others under the shade and shelter of trees, and all succeed well. We have transplanted large specimens from May to November, and from November to May without their showing any signs of being injured; but any one introducing them would probably find small young plants do better than old ones. The young ones bloom when quite small, and I never knew any of them to miss a season without flowering. Any plant becoming too large will bear cutting in freely, as some of our plants at the ends of hedges are clipped in annually, and they never show any signs of having been injured by the operation.—Cambrian, in the *Field*.

French Prize Roses.—The *Journal of Roses*, published in France and devoted exclusively to Roses, has had the happy idea of organising a sort of plebiscite to obtain opinions as to the best Roses. Eighty-five lists were sent in, and from these was made out the following list of the fifty having the most votes:—

La France	79	John Hopper	35
Baronne Adolphe de Rothschild	76	Madame Lacharme	34
Paul Néron	76	Cécile de Chabrillant	33
Gloire de Dijon	72	Louise Odier	33
Souvenir de la Malmaison	72	Marquise de Castellane	33
Jules Margottin	70	Céline Forestier	32
Maréchal Niel	70	Elisabeth Vigneron	32
Baronne Prevost	57	Boule de Neige	31
Gen. Jacqueminot	52	Madame Victor Verdier	30
Captain Christy	50	Thérèse Levet	30
Belle Lyonnaise	47	Géant de Battailles	29
Eugène Appert	47	Rose du Roi	29
Louis Van Houtte	47	Triomphe de l'Exposition	28
Anna de Diesbach	47	Elise Boëlle	27
Aimée Vibert	44	Lord Raglan	27
Souvenir de la Reine d'Angleterre	43	Camille Bernardin	26
Charles Margottin	42	Duchesse de Cambacéres	26
La Reine	42	Lamarqué	26
Victor Verdier	42	Marie Van Houtte	25
Charles Lefèvre	41	M. Boncenne	25
Comtesse d'Oxford	39	Ophirie	25
Madame Boll	39	Alfred Colombe	24
Gloire de Ducher	36	Empereur du Maroc	23
Madame Falcot	36	Jean Pernet	22
		Madame Scipion Cochet	22
		Chromatella	22

The figures show the number of votes given to each.—*L'Illustration Horticole.*

Garden Ornaments.—Having noticed an article in Gardening (No. 70) under the above heading, I give my experience of a few ornaments which I made last summer. For the centre of my garden I made a rustic box as follows:—I bought half a butter firkin (3d.) as a receptacle for the earth; I then bored holes in the bottom with a red-hot kitchen poker (not having an augur) for drainage; the tripod stand I made from a clothes-prop (8d.), and fitted the three projections at the top into the bottom of the tub by making larger holes. I then bought from a florist 1s. worth of virgin cork, and nailed it with French nails on to the tub, and put one or two pieces on to the tripod stand, and the spaces between the cork I filled with moss.

I then varnished the whole once or twice and let it stand until perfectly dry. I then filled the tub with good mould mixed with road drift, &c., and planted in it four plants of Creeping Jenny, one Scarlet Geranium (for the centre), two Nasturtiums (continuous bloomers), two Lobelias, one small Fuchsia, one Ice Plant, and one or two other small things to give a variety of foliage. When the continuous bloomers began to grow I formed a small arch of cane (1½d.), and twined them over it with good effect. The ends of the cane I inserted in the earth of the box. The Creeping Jenny I kept in position over the sides by fixing the strands with tiny loops of wire such as are used by bell-hangers for keeping bell wires in their places.—A. H. B.

Sweet Williams.—I have some plants which show how much Sweet Williams have become improved as regards large pips, fine form, and many and varied colours. Some belong to Hunt's strain, and are characterised by smooth-edged petals, whilst the Auricula-eyed kinds show the white eye, and invariably a serrated edge. The distinguishing feature of Hunt's strain is, however, the ring or ground of some deep colour, and a distinct margin or edging of white. These are always the most effective forms for exhibition, as they come more nearly to the florist's ideal than others do. But whilst the one strain will retain in some flowers the white eye, and the other its correct and defined edging, there will come from each such diverse forms that it is impossible to say to which strain this or that one may belong; and thus the maintenance of such distinctions becomes not only impossible, but useless. The finest strain to be found is made up of selections for several years of the above strains, and where there has been year after year the greatest care exercised as regards the production of only the finest flowers, largest trusses, and most varied markings. The only self flowers are those which are pure white, pink, or crimson; all others are parti-coloured or variously marked, some very prettily mottled, others more or less edged with white or pale pink. Large beds of these Sweet Williams are really grand, and so full of variety and beauty as to be almost unapproachable in effect and interest. If some of these striking forms could be permanently fixed and offered as such, it would largely tend to popularise the Sweet William as a showy border plant.—A. D.

Old Pelargoniums better than Young Ones.—Where Pelargoniums are required for summer decoration it is much better to retain a good supply of old plants than to trust exclusively to fresh-struck cuttings. When the beds are cleared in autumn we go over all the sorts that are desired for the following season, and, selecting all the healthiest plants, cut them down quite close, shortening the long straggling roots; they are then packed thickly into cutting boxes in fine, light soil and kept rather dry. During the winter they are kept as cool and airy as possible in fruit houses at rest, and in spring, when vegetation becomes more active, they are shaken out. The best shaped plants are potted for vases and window boxes, and the remainder is tied up in Moss with a handful of soil and set closely together in brick pits, where they can be fully exposed on favourable occasions until required for planting out. By using a good proportion of these plants the beds may be pretty well filled at once, and an early display of bloom secured. In moist seasons young plants are liable to run too much to leaf instead of to flower, whereas old cut-down plants flower profusely in all seasons, while for single specimens in vases plants with dwarf, bushy habit are indispensable; and few plants so well withstand the trying conditions under which they are thus placed and furnish such good results as these. Single specimens in small vases of distinct colours, or large vases filled with mixed varieties and edged with the beautiful trailing varieties of the Ivy-leaved section, will be found as continuous and satisfactory as any plants grown.—J. G. H.

August-sown Annuals.—Anybody for a very trifling outlay may have a gay garden next spring by sowing now a few seeds of the following annuals, viz., Nemophila insignis, Collinsia bicolor, crimson and white Candytuft, Saponaria calabrica, crimson and white Godetia, Virginian Stock, white and pink Silene, Limnanthes Douglasi, and Myosotis dissitiflora. It is late for the Myosotis, but it is better to sow late than be without it. I have no occasion to sow this now, for so many self-sown plants come up, that one has only to refrain from hoeing them up to have plenty to plant anywhere. Sow thinly either in drills or broadcast in some open situation, and transplant to their blooming quarters early in November, as a good early bloom cannot be ensured by late sowing and late planting.—H.

HARDY ANNUALS.

Gilias.—These are beautiful hardy annuals bearing a profusion of blue, rose, white, purple,

Gilia linifolia.

and other coloured blossoms. In light, dry soils the seed should be sown in autumn; but in cold, wet soils in March or April. The best are G. achilleæfolia, capitata, tricolor, and linifolia.

Kaulfussia amelliodes.—This is also a good hardy annual, either for the open ground

Kaulfussia amelliodes.

or in pots for the window. It was one of the most attractive among annuals exhibited at Regent's Park during last month.

Large-flowering Chrysanthemums.—The leading shoots of these, whether in pots or in the open ground, should be kept securely tied out. The plants must be well watered in dry weather, and a little liquid manure once a week onwards will be of great advantage. The Pompone varieties should now be stopped for the last time without delay; it should be done by the first week in August. Plants in pots are greatly helped by tying out the shoots so as to admit a free circulation of air; they must be also well watered, as the foliage quickly turns yellow when the plants suffer from drought. Sprinkling overhead night and morning is of great service; at this time of year green fly is apt to infest the points of the shoots—a washing with Fowler's Insecticide will soon dislodge the enemy.

HARDY FLOWERS AND THE LONDON PARKS.

THE reaction in favour of these is undoubtedly a reality, and one that is likely to spread and bear good fruit as regards bringing back into cultivation many really beautiful classes of plants that have too long been banished from our gardens. I have no doubt that several varieties of once popular bedding plants, notably Verbenas, are worn out by excessive propagation; the stock plants, being put into a high temperature to yield cuttings, produce one or two good batches, and then quantities of weedy Grass-like ones from the first predisposed to disease. I have just been looking at a retired gardener's flower borders, which are always gay and pleasant to look upon, except when severe frost or snow renders out-door flowers an impossibility. But from the earliest Aconite, Snowdrop, and Hepatica, and throughout at least nine months of the year there is a constant succession of floral beauty. They are not arranged in rows, as in botanic gardens, but, if I may coin a phrase, in regular irregularity, for they are graduated as to height, and although planted in masses or groups, apparently without any relation to each other, yet there is no confusion or jumbling together. There is plenty of room for taste in arranging hardy flowers as well as carpet beds.

A correspondent of mine, pretty well acquainted with horticulture and horticulturists, wrote to me lately saying that in the time when spring flowers should have been plentiful he took a friend to see the alpine garden in Battersea Park, when to his dismay he found only a few Violas, and in the shrub line Berberis stenophylla and Pyrus japonica in flower, so to set himself right he had to return to his own little private garden and there show him his beds of Auriculas, Pansies, Primroses, Wallflowers, single and double, various Daisies, Forget-me-nots, Tulips, single and double, Polyanthuses, Arabis, Ficaria ranunculoides, Caltha palustris, Anemones, Aubrietias, Narcissi, dwarf Phloxes, Primula denticulata, Corydalis lutea, and Erica carnea.

In the way of ornamental foliage he had variegated Sage, Funkia, variegated Ivies, and others—enough to make any garden gay and beautiful in the most lovely of all seasons, viz., the spring. He wonders why the parks and gardens of London lavish all their great expenditure on plants that perish with the first frost, while hosts of lovely hardy flowers are delighting the dwellers in rural hamlets with their freshness and sweetness. I have been told that the display is kept for the London season; but what about the toiling millions who never leave London? Do not they enjoy flowers as much as those who can afford to go in and out of town at certain seasons to enjoy country flowers and fresh air? The parks are really meant for that broad designation of classes called—the people. J. G.

William Bull and Madame Gueuret Pinks.—During the Franco-German war the so-called "Iron-stemmed" Pinks, which were first grown by M. Alégatière at Lyons, completely disappeared, with the exception of one variety, supposed to be the kind named William Bull, which was found amongst the collection exhibited at the Champ de Mars, 1878, by M. Gueuret, from one of whose plants the accompanying illustration has been prepared. The illustration will give some idea of the bushy, free-flowering habit of this beautiful variety. The William Bull variety on the left bears flowers of a bright rose carmine, more or less streaked with violet, with slaty reflections. The William Bull begins to flower about the end of May and beginning of June, when the plants may be bedded-out. The Madame Gueuret variety is entirely an off-shoot of the William Bull,

and differs from it in the flowers being of a blood-red colour, with violet-pink reflections. In addition to their bushy habit these Pinks possess, according to the *Revue Horticole*, a delicious odour, are perennial, and are easily forced. They are also well adapted for outdoor cultivation.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

August 2.—Sowing Tennis Ball, Bath Cos, Neapolitan, and Drumhead Cabbage Lettuce, Radishes, and winter Cucumbers; also Mignonette in pots; potting young scented-leaved Pelargoniums, Balsams, and Carnations; also Strawberries; putting in cuttings of variegated Pelargoniums, named Cinerarias; planting a good breadth of Endive, Cauliflower, and Grange's Broccoli; staking Chrysanthemums, dwarf Dahlias, Calceolarias, and late Peas; nailing Apricots; shifting Primulas and old stools of Poinsettia; cutting down Pelargoniums; exposing fruit on trees in late Peach house to the sun; making trenches for Leeks; layering Strawberry plants for planting out-of-doors; earthing up Broccoli; digging ground for Wallflowers; hoeing among Roses; clipping hedges.

August 3.—Sowing Schizanthus and latest Balsams; potting young Strawberries for planting out, consisting of Garibaldi, Keen's Seedling, President, Dr. Hogg, Oscar, Eclipse, Sir Harry, Elton Pine, a few Black Prince, British Queen, and Sir Joseph Paxton; likewise last-sown Cinerarias and Carnations; putting in cuttings of Bijou Pelargonium, Coleus, and Alternanthera; planting Leeks in trenches; shifting Primulas into flowering pots, Wigandias into 8-in. pots, also Stocks, and parting and re-potting Caladiums; matting Red Currants on walls; staking and tying Dahlias and blue Larkspurs; pulling up Onions; cutting Lavender; hoeing amongst plants in borders; turning old bulbs out of their pots; digging ground for Spinach; earthing up Broccoli.

August 4.—Sowing Radishes and Lettuce; potting Strawberry plants, finishing with Sir Charles Napier; potting some Stocks and Wallflowers for spring three in a pot, and also second-sown Stocks for stands; putting in cuttings of Mimulus, also Iresine and Alternantheras; layering Anne Boleyn and other Pinks; staking Chrysanthemums and Gladioli; moving herbaceous Calceolarias to shady place in frame; pulling off all old Beans from first and second crops of French Beans; cleaning and pruning Roses; earthing up early Celery; hoeing among French Beans, and thinning Mignonette.

August 5.—Sowing Tropoli Onions; potting intermediate Stocks, and potting off all forcing Strawberry plants; planting Lettuce and Endive, also some Stocks and Wallflowers and more Chrysanthemums and Pinks; tying and staking Dahlias; shifting Heliotropes from 5-in. to 7-in. pots; moving Tree Mignonette out-of-doors; shifting President and other Strawberry plants into their fruiting pots; taking up Garlic and Shallots; thinning Chicory; clipping Yew hedges; cutting off Hollyhocks 16 in. above stakes; removing faded Sweet William stems; earthing up Brussels Sprouts and manuring land for Turnips; digging ground for Onions, Cauliflower, and Broccoli; preparing a frame for cuttings; watering Rhododendrons.

August 6.—Sowing Endive for spring crop; also Intermediate Stocks; putting in cuttings of variegated Pelargoniums; planting Wallflowers, also July-sown Bath Cos Lettuce, and some Paris Cos and Ne plus Ultra Cabbage Lettuce; netting Gooseberries; repotting standard Heliotropes and scented Verbenas; lifting Myatt's Prolific Potatoes for seed; clipping hedges, clearing away Nettles and rubbish among Laurels and other shrubs; clearing land for winter Spinach and Endive; digging Potato ground for Turnips.

August 7.—Sowing Nemophila; also main crops of Prickly Spinach, Veitch's Incomparable, Reliance, Imperial, Queen, Little Pixie, Enfield and Red Cabbages, Walcheren Cauliflower, Snow's and Osborn's Broccoli, Tripoli Onions, and Cucumbers; potting Sir Joseph Paxton Strawberry for forcing; potting off winter Heliotrope cuttings; also potting from open ground Calla æthiopica; planting a few more Cauliflowers and some more Curled Endive; also a large breadth of Coleworts; layering Carnations; also Strawberry runners for planting; examining wall trees and Vines for insects; clipping hedges; cleaning and sanding walks; earthing up Winter Greens and May-sown Cauliflower; giving air to Hamburgh Grapes which are ripe to keep them cool.

Flower Garden.

This is a good time to fill up any spare space there may still be in mixed flower borders with seedling Wallflowers, Antirrhinums, Pentstemons, and Sweet Williams. Plant them out in clumps of three or five plants together, and give them a good watering when they are first put out. All the attention required afterwards is protection from slugs until they have become well established. Herbaceous plants generally need attention as to ties and supports and weeding. Dahlias, Hollyhocks, and all large-growing sub-tropical plants should be frequently looked over, and be kept tied to stakes as growth progresses. Roses should have all decayed flowers cut off at least twice a week, an operation which will tend to the earlier production of a second bloom. Stir the ground about them deeply, and if they lack vigour of growth, give a good dressing of guano; its effects will soon be visible in the darker hue of the foliage.

Carnations and Picotees.—These ought to have daily attention. Every day it is necessary to look to the flowers, the calyxes of which have a tendency to split and to open them out on the opposite side, tying them round with a strip of bast. Green fly will cling to the youngest buds, and it also attacks the young growths under glass; it ought, therefore, to be brushed off.

Delphiniums.—If it is not intended to save seeds of these the seed-pods should be removed in a green state; this will cause the side stems to flower stronger.

Pentstemons and Antirrhinums.—These useful hardy plants are now coming into bloom, a condition in which they will continue until frost sets in. Tie the stems to sticks as they advance in growth, and keep the beds in which they are planted cleared of weeds.

Glasshouses.

Aquatic Plants.—Aquatic plants are not nearly so much grown under glass as they deserve to be. No greenhouse need be without a suitable place for growing such aquatic plants as will thrive in a usual greenhouse temperature. It may be formed by ordinary stone or slate slabs put together in the usual method, or it may be a wooden trough lined with lead, the outside of which, if desirable, can be covered with cork or other material to give it a rustic appearance. Its dimensions will require to be in keeping with the size of the house; a depth of 2 ft. will be sufficient, and the plants should in a great measure be confined to pots, as the stronger-growing species will this way be under more control, and their arrangement can be altered at will, so as to avoid the, to many, objectionable feature of plants always occupying the same positions. Such a receptacle as that just described should be supplied with water by means of a pipe and tap that will give a slow trickle for some hours almost daily, with a corresponding outlet by an ordinary overflow, with means to convey the water away. In this matter there will be little difficulty if there happens to be a tank beneath the floor for holding the roof water. One of the most suitable plants for growing in conservatories is the Cape Pond-weed, Aponogeton distachyon; its singular highly fragrant, Hawthorn-scented flowers emit the most agreeable perfume, and they continue in bloom through a great portion of the spring and summer. It should be grown in pots in loam and placed a few inches below the surface of the water, setting the pots which the plants occupy upon others inverted. A few examples of the Grass-like leaved Vallisneria spiralis may also be grown; its leaves when placed under the microscope show the circulation of the sap so well as to make them objects of interest. It will succeed in 6-in. or 8-in. pots, with a few crocks in the bottom, and filled with loam. The pots containing it may stand on the bottom of the tank. Trapa natans (the Water Chestnut) is another subject deserving of notice. It will grow in soil similar to that recommended for the Vallisneria, but it requires a larger pot. The North American white Nymphæa odorata will need a moderate-sized pot, and associated with it may also be the Chinese N. pygmæa, a white-flowered kind which will likewise succeed in loam and similarly treated. Dietes bicolor is another plant that does well managed in this way. It should be potted in loam, and is distinct in habit. The North American Orontium aquaticum will be a good addition, as would also be the Chinese Sagittaria sinensis; loam, with a little sand, will answer for this. To these may be added the green and variegated-leaved Callas, which succeed well in loam, and may stand with their pots from 12 in. to 6 in. beneath the water, according as their heads will look best. These Callas should not be allowed to get too large; they may be divided yearly if necessary, and, if thought desirable, can be grown as ordinary greenhouse plants, and be introduced to the water when coming into flower and removed afterwards to make room for others. In this way a considerable succession of bloom may be kept up. There is always a charm attached to plants grown in water this way, but it is essential that the water be kept clean.

Iron stemmed Pinks (William Bull and Madame Gueuret).

Dwarf-growing Ferns, such as Adiantum cuneatum, A. gracillimum, and the taller A. formosum, together with the many crested forms of Pteris serrulata, P. cretica albo-lineata, and also the green P. cretica—the latter one of the best of all Ferns for bearing hard usage—may with advantage be interspersed amongst the dwarfer-growing subjects in the greenhouse. All plants introduced to conservatories from warmer quarters must be carefully treated as regards water, which should only be applied at a temperature approaching that to which the plants have been accustomed; but they should receive no more than is necessary to prevent the soil from getting so dry as to cause them to flag.

Achimenes and Gloxinias.—Some of the latest-started that have received as cool treatment through the summer as they could be induced to make progress under, will, when beginning to flower, be in the best condition for standing in the conservatory, being careful not to admit the cool external air directly in contact with them. Where plants are arranged in groups on the floor, or on low table-like stages, it is always well to avoid the pots being more seen than is necessary; and, in order to effect this, sufficient numbers of Isolepis gracilis and Lycopodium denticulatum should be grown in 4-in. or 5-in. pots, so as to stand as close as the pots will admit in the immediate front of the

arranged groups. A good effect may be produced by introducing amongst these green plants Coprosma Baueriana variegata and small examples of the white-leaved Centaureas, together with anything else at hand that will take off the stiff formality of rows of one or more kinds.

Plumbago capensis.—Few plants are so useful as this at this season of the year, grown in small pots, either for large conservatories, small greenhouses, or anywhere where blooming subjects are required. Plants that have already been in flower for some time will generally push up side shoots from the stronger branches, which make excellent cuttings if taken off now and treated in the ordinary way; they will get established before winter, and will make serviceable flowering stock for next summer. A sufficient number should be prepared, as they are of much more use in a small than in a large state, and the delicate blue shade of the flowers furnishes a colour which we need, and which harmonises well with everything else it is associated with.

Fuchsias.—These strike like weeds, and the present is the best time in the year for putting in cuttings in order to get young stock that will bloom as early in the spring as is required in a comparatively small state; or they may be grown on at the option of the cultivator to as large a size as may be considered requisite for later flowering. Shoots that have formed bloom root indifferently, and never make good plants. Young growths should be chosen from near the base of the stronger branches. Put these say half-a-dozen together in 5-in. or 6-in. pots drained and filled with sandy soil, covering with a bell-glass. Keep them moist and shaded in a little warmth. Take care that the cuttings previous to insertion are free from aphides and red spider, especially the latter, to which Fuchsias are subject at this time of the year. Out of the many fine varieties that now exist there need be no lack of choice; but there is a great difference in their inclination to flower early. Amongst all that have been raised, none find so much favour with market growers as regards their early free-blooming disposition as the white rose-corollared variety called Mrs. Marshall (syn. Arabella) and the crimson kind, with violet corolla, named Try-Me-O. The plants which bloomed early, and which are now getting shabby, should be turned out of doors for a fortnight, and should receive no more water than will keep them from flagging too much; then let their side branches be well shortened in and the main stem slightly reduced, giving a good washing with Tobacco water, to which a little Gishurst has been added, so as to free them from aphides, thrips, and their eggs, and then put them in a pit that can be kept close and slightly shaded. Thus treated and syringed overhead daily, they will quickly break into fresh growth. If in comparatively little pots they may have a small shift; but if they have sufficient room already, weak manure water will answer. Under this treatment they will again get well furnished with branches that will keep on flowering until the end of October or later, and they will be found very serviceable for greenhouse and conservatory decoration, as well as for cutting, in which condition their flowers will last much longer than earlier in the season.

Petunias.—The beautiful single forms of these raised from seed sown early in spring furnish useful decorative flowering plants through the summer for conservatories and greenhouses; but their natural straggling habit is a defect that does not exist in the double-flowered kinds. The latter keep on blooming for months without getting at all denuded of their leaves or unsightly. These are increased by means of cuttings, which for flowering next year should be put in now, selecting for the purpose the young soft shoots that will generally be found springing from near the base of the plants now in bloom. Treated in the usual way they will root in a few weeks, when they should be moved singly into 3-in. pots into sandy loam, and placed through the autumn and winter on a shelf near the glass, where they will keep on making slow progress and be in a proper state for moving on early in the spring. Petunias, both double and single, that have been blooming for some time will be much benefited by the use of manure water.

Vallota purpurea.—This beautiful plant is one of the most useful which we have through this and the succeeding month, as where a sufficient stock of it exists there is no difficulty in having it to come in in succession during that time. It is most serviceable when grown in from 6-in. to 9-in. pots, with from a couple to half-a-dozen bulbs in each, as it does not like too much root-room. After the flower-stalk first shows itself the blooms come on very rapidly, and where a succession is needed a portion of the plants may be retarded by placing them in a frame at the north side of a wall, where they will be little under the influence of the sun. The Vallota is a plant that requires to be kept always moderately moist, especially when exposed to sunshine; but whilst in chilly quarters it must not be kept over moist. Attend to advancing stock of this plant taken off in the spring from the larger bulbs; give all the light that a good well-glazed house affords and plenty of water, by which means the bulbs will increase to a blooming size much quicker than if subjected to comparative neglect.

Late Heliotropes.—Plants of these propagated in spring will now be found useful for blooming late in the autumn when flowers are scarce. They are always acceptable both on account of their colour and perfume. To have them in a condition to bloom freely they must be well attended to; when their pots are full of roots manure water will much assist them. The old variety is still a general favourite, but under glass rather light coloured. Etoile de Marseille is a fine kind as regards colour, as is also Madame Fillion. Standard and other large plants that have bloomed for a considerable time under glass should be supplied weekly with manure water sufficiently diluted, as by no other means can plants that continue through the season producing a succession of growth and flowers be kept in the vigorous condition which is essential not only to their healthy appearance, but to enable them to bear the full amount of bloom of which they are capable.

Chrysanthemums.—The time is now come when Chrysanthemums want the most careful attention, without which, no matter how well they have been treated in the early stages of their growth, or what may be subsequently done for them when nearer blooming, they will fail to give satisfaction, for, now as their pots are getting full of roots, should there be any neglect in not keeping the soil sufficiently moist, or in supplying them with liquid manure regularly, they will neither retain their foliage in a fresh healthy state down to the base, nor will they produce such a head of fully developed flowers as they otherwise would do. Where the plants are plunged see that the roots do not grow through the bottoms of the pots. Keep the branches regularly tied so as to avoid breakage through wind, and place them sufficiently far apart in a light position to prevent them becoming drawn, and to admit of getting amongst them to water and syringe them, which latter operation should be practised in the evening of every dry day.

Pelargoniums. — The earliest-flowered large varieties of these that were turned into the open air recently should, now that the lower part of their shoots will have assumed a hard brown colour indicative of the necessary ripened condition, be cut down, leaving two or three eyes (according to the size of the specimens) above where the shoots spring from, and as soon as the heads are thus removed place the plants in a pit or frame, where they will be protected from too much wet; keep them a little close and syringe them overhead daily. Thus managed they will push young growths forthwith. The fancy varieties may be treated in a similar manner, but they do not require (nor will they bear) cutting in nearly so close as the large-flowered kinds, and in their case it is even more necessary to be careful that the roots do not get too wet.

Hardy Fruit.

Strawberries.—The plants should now be cleared of runners and the ground "pointed" over. New plantations may also be made, either with forced plants or newly-formed runners. Deeply and well-enriched ground is indispensable to the production of fine Strawberries.

Raspberries.—It will now be necessary to thin out the new canes to the minimum point—about three to each stool—and as soon as the fruit has all been gathered, any of the old canes that interfere with the full development of the new growths should be removed. In order to prevent injury from wind, the new canes should also be tied in at once.

The new shoots and points of cordon and espalier-trained trees of Apples and Pears may likewise now be tied in. Spur back all growths not required for furnishing the trees to within three joints of the old wood, an operation which, combined with partial root-pruning at the proper season, will conduce to fruitfulness. The majority of Peaches and Apricots may now have the current year's shoots laid or tied in to the wall, but previously pinch closely back all sub-lateral growths that have formed on them. Any trees that have suffered from the effects of last winter's severity and which have not yet fully recovered their former vigour, may still be left to grow unrestrictedly, but no fruit must be expected from them next season. Keep down aphides and red spider by occasional syringings with soap-suds or a weak solution of Gishurst Compound.

Vegetables.

Onions.—A little winter Onion seed should be sown; it is better to put some in now, and again in a fortnight's time, than to trust to one sowing; as in severe winters the plants from one will frequently succeed when the others fail. Very much depends on the kind of weather prevailing during the autumn, for the young plants of the first sowing will sometimes get a little too large, and in other seasons the second will be too late. Prepare the ground well by deep digging and moderate manuring; sow in rows 1 ft. apart. In very bleak, cold situations the White Lisbon, being very hardy, is suitable for sowing; in milder localities, Giant Rocca and Globe Tripoli are good kinds.

Cut out the flower-stems of Globe Artichokes as soon as the heads are gathered; neglect in this matter at this season is often the cause of the plants dying off through the winter. The young growth makes little progress until the old stumps are removed, not having time to get strong enough before autumn. Finish planting late Broccoli and all kinds of winter greens. Walcheren and Veitch's Autumn Giant Cauliflowers should also be planted for late autumn use on well manured land in an open position. Sow a good breadth of Prickly Spinach for standing the winter. Parsley may yet be sown for late spring picking; it will not run to seed quite so soon as that sown earlier. Make a good sowing of Endive, of both the green-curled and Batavian varieties, for winter. The earliest sown crop will now be full grown, and portions of it should be tied up and blanched in succession. The blanching may easily be effected at this season by covering each plant with an inverted flower-pot, with a bit of Moss twisted into the hole to keep out wet, air, and light. Plants from the successional sowings should be planted out on well prepared land, 1 ft. apart, at intervals of two or three weeks.

A Pretty Town Garden.—With a little trouble and taste the small but valuable spaces to be found in front of town houses might be converted into charming little gardens. One of these, which I noticed the other day in the neighbourhood of London, might be advantageously taken as an example. It is about 25 ft. square and fenced round, but the fences are completely hidden by a white Jasmine literally covered with blossoms. Two plants of this Jasmine are also trained on each side of the windows, which themselves, as well as a small balcony, are gracefully draped with a mixture of Virginian Creeper, scarlet Nasturtiums, Blue Convolvuluses, Creepy Jenny, and Tropæolum canariense, all easily grown plants and admirably adapted for such purposes. On the shady side of the Jasmine hedges are planted Ferns amongst rough stones, and on the sunny side annuals of various kinds. In the centre (which is Grass) is a fine specimen of Rhus glabra (one of the most valuable of town shrubs), and round its base is a mass of blue Lobelias. The effect of this arrangement was charming. Where more variety is desired it may easily be had, as there are numbers of other plants which thrive equally well in most of our small suburban gardens.—S. E.

GLASSHOUSES AND FRAMES.

LOBELIAS AND HOW TO GROW THEM.

In the open air and in pots the Lobelia is one of the most important of plants; hardly any flower garden is now considered complete without one or more beds or borders being plentifully supplied with the beautiful Lobelia speciosa or some of its many varieties, such as Lustrous, Blue Stone, Blue King, and the lovely Paxtoniana, a white variety margined with blue. There are also one or two pure white Lobelias of the speciosa section with flowers nearly as large as the species. Of the smaller or pumila section of L. speciosa, magnifica, grandiflora, and Mrs. Murphy (pure white) are perhaps among the best. The double variety is also magnificent where it succeeds well, but it is very erratic, and hardly to be depended upon in beds or borders, sometimes forming a complete sheet of bloom, and at others the shoots running up through it, as it were, overpowering and preventing it from blooming, presenting the appearance of tufts of Grass. It seems difficult, perhaps impossible, to guard against this peculiarity, inasmuch as where the plant is perfect in form and flowering one season it becomes weedy-looking the next. This double blue is, however, a grand subject for culture, and under the superior climatal conditions that glass affords it comes with greater certainty, and hardly any plant can equal the richness and beauty of this double Lobelia crowned as thickly as possible with its lovely balls of beautiful blue.

The chief points to start with in the successful culture of the Lobelia are good soil and well-grown established plants. The soil should be light and rich, and rest on a dry and perfectly drained bottom. The Lobelia enjoys abundance of water when in robust and free growth, but nothing is more fatal to its well-doing than stagnant water at the roots—if on a porous bottom it may be plentifully watered during a dry time in summer without fear of injuring the roots, neither can the roots of Lobelia make way nor the plants thrive in a strong adhesive soil composed of clay or heavy loam, or if the compost be heavy, it must be lightened by a plentiful addition of leaf-mould, sand, or peat. The Lobelia thrives admirably in equal parts of rather sandy loam and leaf-mould with a fair admixture of sand to keep it open. Charcoal-dust and peat also form capital additions to loam for their successful culture; likewise spent manure from Mushroom beds. A slight mulching of one-year-old sifted hotbed manure will be found a capital addition to beds or borders for keeping out the drought from and nourishing the roots of Lobelias through a dry season. One of the greatest difficulties, however, in carrying Lobelias in full beauty through the season is the freedom with which they produce seed and the tentative mode in which it is ripened—a pod at a time almost is the order of ripening. But where flowers are the object, this stage of maturity should never be reached. The moment the flowers fade they should be picked off, and so on persistently every week or ten days throughout the season. Of course the labour is great, but so is the reward. Few features in the flower beds or borders are more thoroughly enjoyable and satisfactory than a perfect band or small bed of any of the varieties of Lobelia speciosa from the middle of June till the frost clears the garden of its autumnal beauty. Of course this mode of culture prevents the saving of seeds, but this is of little moment, as it is better to purchase them than save them. If, however, any plants of unusual merit, distinctness, or improvement in size, colour, or substance of flower, appear, it is easy to perpetuate such, either by means of cuttings, rooted branches, or by lifting the plant, potting it, and placing it in a gentle bottom-heat until established; after that, set it on a light, airy greenhouse or forcing-house shelf, when it may be increased by cuttings and root division to any extent in the spring, planting a stock on a piece of reserve ground for seed. This increase by cuttings, rooted side-shoots, or conservation of the old plants by potting a few of them in the autumn, is also the best method of preserving and increasing the stock of special varieties. The seeds of even the truest types vary considerably from each other, and also from the original, and to this inherent variability we owe the many kinds of Lobelia speciosa that add so largely to the enrichment of our flower gardens. It is, nevertheless, mortifying when white or semi-white flowers break forth among the truest strains of Blue King, or tall speciosas revert from the most carefully selected stock of L. pumila grandiflora. To avoid the risk of all this strike cuttings, plant rooted layers during the summer, or pot sufficient old plants for stock in the autumn.

The Lobelia strikes roots freely in a brisk heat in a moist propagating pit or frame in spring. These cuttings should be potted or boxed off, and got into bulk by the end of May in exactly the same way as seedlings sown in heat in September, October, or February. Those who want early Lobelias from seed should sow in the autumn, and prick the seedlings off in boxes or pans, or shift them into 2½-in. pots before winter. Store them on shelves near the light exposed to abundance of air, give another shift into small 6-in. pots in March into equal parts of leaf-mould and loam, and such plants will be perfect for planting by the end of May. Spring-sown seedlings may go into smaller-sized pots and be planted rather more closely, but will not flower so early or so well. On the whole, therefore, autumnal propagation, either by means of cuttings or seeds, is preferable to the sowing of the seeds in spring. For pot culture these autumn-sown plants are best. They are merely pushed on a little farther till they are large enough to fill a 6-in. or 8-in. pot; the first size is the best, the second as large as any pot should be for a single Lobelia speciosa. The taller-growing sections may be stopped a few times during the earlier stages of growth, to cause them to grow horizontally. At the final shift the plants should be kept well up in the pots, so as to allow the shoots to fall over the sides and cover them as they grow and flower. In the case of well-grown plants belonging to the taller sections, such as Paxtoniana, one of the chief merits of pot plants is that of drooping over and wholly hiding the pots. In the pumila section the plants are too dwarf to do this, but the rim may be entirely covered by a carpet of blue. The double blue is also of this dense habit, and is inimitable for the decoration of light-coloured marble, glass, or silver vases, or flat baskets. Some of the taller ones are also admirable for the furnishing of small hanging baskets or raised stands. The soil for Lobelias in pots should be equal parts of leaf-mould and loam, mixed freely with silver sand or charcoal dust. The drainage should be clean and ample, and over it should be put a layer of small pieces of manure about the size of marbles, and almost as hard, such as that of cows at least two years old, mixed with a little Cocoa-nut fibre refuse, to ensure a thorough and nourishing drainage.

When the plants are in full growth and flower they enjoy manure water at least once a week; that made of a slight admixture of guano and soot suits them admirably. Having such a limited root-run, these plants must never once be allowed to become dry, and if carefully attended to they will continue long in beauty. When done blooming they may be cut down, repotted, and used for flowering again or for stock. With about three lots of Lobelias in pots to be brought on in succession, the conservatory, window garden, or sitting-room need seldom be without the enlivening and enriching presence of these lovely plants from April to November. T. F.

Tuberous Begonias from Seed.—The experiences of various persons in regard to raising tuberous Begonias from seed seem to differ considerably. In February last, seeing in this paper an assertion that it could be raised without heat, I resolved to try, as I had not yet attempted Begonia raising. I procured a 1s. packet and sowed it as instructed, placing the pan in the greenhouse; after waiting three weeks no plants began to appear, and therefore I thought it best not to rely on that batch, even if any came, so I got another packet, sowed it in the same manner, and placed the pan this time in a hotbed, with a bottom-heat of about 70°, removing the first pan to the same place. In about a week some of the first sown began to appear, and next week the second batch came up well, and soon out-grew the first, which in about a month perished altogether, but the second lot came on admirably, and I have now ninety-four nice healthy little plants in separate pots, and I firmly believe that had not the soil began to turn green before the last of them were fit to move, I should have got quite forty more. I removed them to the greenhouse as soon as pricked out. Your correspondent "J. C. B." says, "cover the seed with ¼ in. of compost." This must be a mistake, for such minute seed, as small as dust, could not possibly get through this. If "C.'s (Byfleet)" instructions be carried out, satisfactory results will follow.—Floropihlus.

Cyclamens.—A sowing of seed of these beautiful spring-flowering plants should be made without delay. There is nothing like shallow pans in which to sow the seed, and the soil should be a fine, free, sandy one. The pans require to be placed in a brisk, moist bottom-heat, with a piece of glass over the pans. The seed, if full and well ripened, soon germinates, and when the plants are large enough to have put forth three leaves they should be pricked off into 5-in. pots in a rich, light soil; the pots should be well drained. The growers of Cyclamens in quantity are now busily engaged in getting their seed sown, and their practice is the one just set forth. Seedlings raised from seed sown in August make good plants to flower fifteen months afterwards if they be grown on as fast and as liberally as possible.

Winter Mignonette.—Seed of this should now be sown to flower in the winter. For this drain some 6-in. pots; use ordinary loam, to which add one-fifth of leaf-mould and rotten manure, as also some sand; with this fill up the pots to within an inch of the rim, smooth the surface, putting a dozen seeds in each, cover lightly, and keep slightly moist. The seeds will germinate in a week or two, when they must have plenty of light and air. An ordinary garden frame, with the lights off, except in very wet weather, is the most suitable place for them during the next six or eight weeks. There is nothing more acceptable either for cutting, greenhouse, or room decoration through the winter or early spring than Mignonette, and it is very suitable for amateurs to cultivate; the principal point to be observed is to give plenty of air and light in the early stages, so as to keep the plants dwarf and stout; if ever they get weak and drawn up, they are worthless.

Profits from Small Greenhouses.—In looking over the volume of Gardening Illustrated, I read the troubles of "Lancashire Working Man," and his appeal for advice to turn his valuable property to account seems deserving of answer. The writer remembers a man who got a golden return from some greenhouses, and this plan might be followed by many who possess small greenhouses and find them rather like white elephants on their hands; but with Cucumber culture, aided by Kidney Beans and spring salad, the houses may be made as profitable as any one could wish. Take for stock the Marquis of Lorne Cucumber (Hamilton), a shy seeder with solid and firm flesh, and the Telegraph Cucumber, excellent either for summer or winter crop. These must be grown in the greenhouse, and with the French Beans in pots, ripened in April and early in May, and in a frame a number of cuttings of Geranium should be ready to come into the house, and Musk grown in the border may be potted off and forced in the frame by the aid of a lamp stove. All these things meet a ready sale in large cities, which we may conclude the "Lancashire Working Man" lives near, and a number of easily grown plants may be flowered in the houses and sold for window decoration as follows:—Hire a low cart and donkey, and fix withies across the cart, covering over with white canvas, and fastening the front and sides firmly down with bast matting or nails, leaving the tail end open; now fill the cart with plants in full bloom, a few late Cucumbers, and some Musk in pots. The woman or boy who acts as vendor should receive 2d. in the 1s. These plants, &c., sold at market prices thus would soon repay the possessor of what too often proves a plague to those who aim at too ambitious results.—Cantab.

Lapagerias.—These are the easiest-grown climbers with which we are acquainted. They require a cool, moist soil and a perfectly cold house, in which the shoots should be trained close to the glass, where they will flower their whole length. The best plan is to stretch wires 4 in. or 5 in. apart for it in the direction in which the shoots are to be led, and they should be allowed to follow the wires themselves, which they will do—twisting along as neatly as possible—without the least assistance, except that when more than one shoot is allowed to a wire care must be taken to prevent the leaves being caught in the twists. To attempt training the shoots by ties is troublesome, and not a successful plan. Stopping the shoots occasionally induces flowers to come sooner than they otherwise would, and produces little spurs, each of which furnishes several flowers. The beautiful white variety is a great favourite for various purposes, and we would recommend those who have it to plant it out at once, however small their plants may be, in a compost of peat, loam, and plenty of sand, with a little rotten manure, and to give it room and light, keeping the soil about the roots rather wet than dry. Our large plant which grows so rampantly every year, though it does not flower so freely, owing to the shade over it, has never been otherwise than wet at the root for three years, on account of the drip from the other pots, and yet it is in fine

Spray of Lapageria.

health and still growing rapidly. The Lapageria makes a disproportionate quantity of large thick roots considering its habit and growth, though the shoots of established plants are sometimes as thick as small pot Vines. The corridor in Messrs. Veitch's nursery is in autumn remarkably gay with white and rose-coloured flowers of L. alba and L. rosea. Instead of the shoots being formally trained to the trellis-work under the roof—a method too frequently practised—they are allowed to droop loosely, by which means, when thickly laden with bell-shaped, waxy flowers, a much better effect is produced. In sunless places in cool houses even in London these plants succeed perfectly, and can therefore scarcely be too highly valued. In Covent Garden Market blooms of these Lapagerias are fixed by means of wire to long shoots of Ficus repens in order to form festoons, wreaths, &c.; this obviates the necessity of mutilating the plants, and, associated with the round, green and bronze leaves of the Ficus, the waxy, bell-shaped flowers of the Lapagerias are equally effective, and shoots of the Ficus can always be had in abundance.—C.

Rhynchospermum jasminoides.—Beautiful as this is when shown as a specimen plant, it cannot compare with plants of it grown on pillars in conservatories. We have at present a pair covering pillars and ornamental girders 20 ft. high, and quite masses of pure white blossoms that emit a delightful fragrance. They thrive amazingly in the intermediate temperature of a conservatory, and the blossoms are invaluable for button-hole and other bouquets.—J. G. L.

SCREENS FOR FIRE-PLACES IN SUMMER.

THE illustration on the next page represents a fire-place jardinière invented by Messrs. Barnard, Bishop, & Barnard. It consists of an ornamental cast-iron box provided with hooks suitable for attaching it to the slow-combustion stoves made by that firm. As, however, few of our readers probably possess such stoves, we may mention an excellent method of forming a screen for any ordinary fire-place in summer, and now is a good time to commence operations. Procure a stout box the length of the fire-place, 12 in. to 15 in. wide, or more if desirable, and 8 in. or 9 in. deep. The front and ends may be painted or varnished according to taste. Perforate the bottom by means of an augur to afford drainage. Then procure sufficient turfy loam to fill the box, and mix with it a liberal quantity of well-decomposed manure and some road sand. After draining the box by placing a large crock over each hole, and putting on these crocks ¼ in. or so of clean gravel, put some of the rough pieces of soil in, then procure from some good nursery two or three good plants of the Irish or other kind of Ivy in pots, well water them, and when they have drained a little turn them out and plant them in the box close to the back. In front and round the ends plant a row of young plants of Creeping Jenny, and fill the middle up with hardy Ferns, which may be procured in pots at a nursery, or in the form of roots in the market. Those in pots will be best. A few pieces of stone may be placed between the Ferns, if desired, to give it a less formal appearance. In each corner at the back of the box must be fastened a stout lath of the height of the fire-place, and to these should be fastened a piece of wire netting to which to train the Ivy, or a wooden lattice would answer as well. Place the box in a partially shaded position out-of-doors. Keep the shoots of the Ivy tied in as they grow, and stop them when they reach the top. Give plenty of water, and in winter the box would be better surrounded with ashes or sand to keep the frost from the roots. In spring cut the Creeping Jenny down close to the soil, and by June a beautiful screen will be formed. A few cut flowers placed in among the Ferns will give a good effect. We must add that the box would be better if provided with a handle at each end, in order that it may be taken out of the room once a week, and the leaves of the Ivy and Ferns receive a thorough washing with the syringe, and the soil receive a good soaking with water.

Staking Tall-growing Potatoes.—Reserve the old Pea-sticks, and stick and tie the tall Potatoes. This will let the sun to the roots, and wonderfully improve the appearance of the plants in small gardens.—W. W., *Belper*.

ANSWERS TO QUERIES.

2576.—**Copying Machine.**—As I have made several of these from various receipts I think I can enlighten "C. H. A." as to "Subscriber's" intended meaning. 2½ oz. of gelatine glue should be steeped for twelve hours in 5 oz. of water (in a jam jar); then place the jar in a saucepan half-full of water, and set on the fire till it is perfectly melted. Stir in the glycerine and the ten drops of carbolic acid, and when the whole is thoroughly mixed, pour it out into the case which is to form your copying machine. It is a good plan while on the fire to stir in ½ oz. of precipitated chalk, as this prevents the ink from adhering too firmly to the compo, and also renders the writing more visible. It should be left a day to settle before using.—FLOROPHILUS.

—— From a receipt which appeared in a previous number I have made a copying machine. First I got made a tin case 18 in. long, 12 in. wide, and 1½ in. deep; then I procured 7½ oz. of Russian glue, 13½ oz. of glycerine, and fifteen to twenty drops of carbolic acid. I then put the glue into a jar with 12 oz. to 14 oz. of water; then placed the jar in a saucepan containing water, and put it near the fire and left till it was quite dissolved. Next I mixed the glycerine and carbolic acid with the glue, and after stirring it well for a few seconds I strained it through a piece of muslin into the pan or case, and left it in a level position for eight or ten hours, and after washing the surface with sponge and cold water it was ready for use, and it has answered admirably. To erase the copies from the mixture it must be washed with the sponge till it has disappeared. To make the ink, get three small penny packets of Crawshaw's or Judson's violet dye and put it to 1 oz. of water, and mix with it two teaspoonfuls of moist sugar. Be sure the copy is quite dry before laying it on the mixture, or it will run.—THOMAS GULLIVER GRIFFIN.

2511.—**Aspects for Hardy Flowers.**—Where a garden is surrounded by walls the endeavour should be made to clothe them with climbers of some kind. Where a variety of aspect exists a considerable amount of pleasure may be derived if the plants are selected with a view to their suitability for the position assigned to them. It is often considered unadvisable or impracticable to train climbing plants to low walls. This is, however, a mistake, as by so planting that each specimen is allowed considerable lateral development, excellent results may be obtained. For a north aspect nothing can equal Ivy, the small leaved variegated kinds being especially pleasing, thriving well and preserving their variegation in such situations much better than when planted in unexposed places. The south wall we would devote to Roses; planting such kinds as Gloire de Dijon, Devoniensis, Duchess of Edinburgh, climbing Victor Verdier, and climbing Jules Margottin. On the east and west walls may be planted Clematis montana, flowering so freely and profusely in spring, C. Fortunei, C. Standishi, and any of the lanuginosa type, such as l. candida, all of which flower upon the old wood, and consequently require but little pruning. Cotoneaster microphylla and Pyrus japonica are excellent subjects for the purpose, as are also the golden variegated Honeysuckles, Escallonia macrantha, Euonymus radicans variegata, Jasminum nudiflorum and revolutum, and Chimonanthus fragrans. The north border would be a congenial home for the various members of the Lily family which delight in shade and shelter. The Orange, the Tiger, the old white, and L. longiflorum should be planted in clumps of several bulbs together, in which manner their characteristic beauty is much better realised than when dotted here and there in the form of isolated specimens. The various interesting species of Cyclamens, such as C. hederæfolium, vernum, Coum, and europæum, also find themselves at home in such a place; but they should be planted somewhat raised above the level of the soil, so as to ensure perfect drainage, in mould composed to a great extent of decomposed vegetable matter. The many beautiful kinds of double and single Primrose and Polyanthus prefer a shady situation; and bulbs, such as Scillas, Fritillaries, Aconites, Snowdrops, Narcissi, and Myosotis dissitiflora, thrive admirably when thus placed. They also last much longer in beauty than when more fully exposed. Christmas

Roses, Pinks, Carnations, Roses, Hepaticas, Delphiniums, Arabis, Alyssum, Daisies, and hardy Fuchsias will succeed in any situation except the north. Sweet Williams and show and fancy Pansies prefer an east aspect, where they get relief from the noonday sun, as do also the bedding Violas and Pansies, which flower continuously up to the autumn, although these latter will do very well in full exposure if well watered in hot water. With respect to beds upon the lawn, I would advise that none be made anywhere in the centre of it; by preserving a free, open expanse of Grass the surrounding features will be brought into greater prominence. If anything is planted in the middle of the Grass plot let it be a Conifer of moderate growth, such as Cryptomeria elegans, Biota elegantissima, or Thuja semper-aurea. At each corner of the lawn a neat-habited flowering shrub might be planted, such as Hydrangea paniculata grandiflora, so beautiful in the autumn, Berberis Darwini always fresh and bright of foliage, and carrying a profusion of bright orange-yellow flowers in spring; the Laurustinus, and Viburnum plicatum, or Spiræa ariæfolia. Near to the margin of the lawn and between each shrub a bed might well be formed. One of these might be devoted to the florists' varieties of the Fuchsia, far too little use of which is made for open-air decoration. Plant them out in well-stirred ground, encourage to liberal growth by means of frequent waterings in hot, dry weather, and at the close of the autumn cut them over close to the ground, and cover the roots with 4 in. of ashes, or, better still, good dung, the manurial properties of which will be worked into the soil by the winter rains. These plants when once well established grow with great vigour and give an enormous wealth of bloom. Good varieties for the purpose consist of Rose of Castile, Mrs. Marshall, Wave of Life, Lady Heytesbury, Avalanche, and Madame Cornellissen. Another bed should be planted with Clematis of the Jackmani type, taking such varieties as Jackmani, rubro-violacea, and rubella. In planting work away all the old soil from the ball, and mulch the surface with rotten dung. Cut back the plants each year to within 6 in. of the soil, and train the shoots as they grow to short stakes inserted crosswise in the ground. The other beds we would devote to hardy annuals, which may be sown from March to May at intervals of ten days.—J. Cornhill.

—— A border which gets only the morning sun will suit Auriculas, Primroses, Polyanthuses, Hepaticas, Christmas Roses, and Pansies. The hardy Cyclamens also do well in a shady place. Pinks, Carnations, Phloxes, Sweet Williams, and Delphiniums want all the sun they can get. Roses will not do well in the kind of garden described. Gloire de Dijon and the old Maiden's Blush do well as standards in districts towards which the prevailing winds do not blow so long as not more than three rows of houses are between the garden and the open country. When even another two rows of houses are added they begin to dwindle. A good selection to begin with would be Annie Alexieff, Comtesse de Chabrillan, Coquette de Blanches, Glory of Waltham, Princess Louise Victoria, Jules Margottin, and General Jacqueminot. As dwarfs on the Manetti these would answer in a large bed cut on the turf if the turf was buried 2 ft. deep under the bed, and plenty of manure worked into the soil.—J. D.

2508.—**To Make Putty.**—The following is the way in which I have often made a superior putty which has stood the weather well: First put out a quantity of whitening into an old bowl or clean vessel of any kind; then pour a little boiled linseed oil on it, and rub up together with a putty-knife or spatula, adding more oil as required until the whole has become tolerably well mixed. Then it will be necessary to take it in the hands and knead and work it about for half-an-hour or more (you cannot get it well mixed any other way); the more it is worked the better it will be. If you please you may add about a fourth part of white lead, which must be well worked in. It will be found a somewhat tedious and by no means pleasant process.—Florophilus.

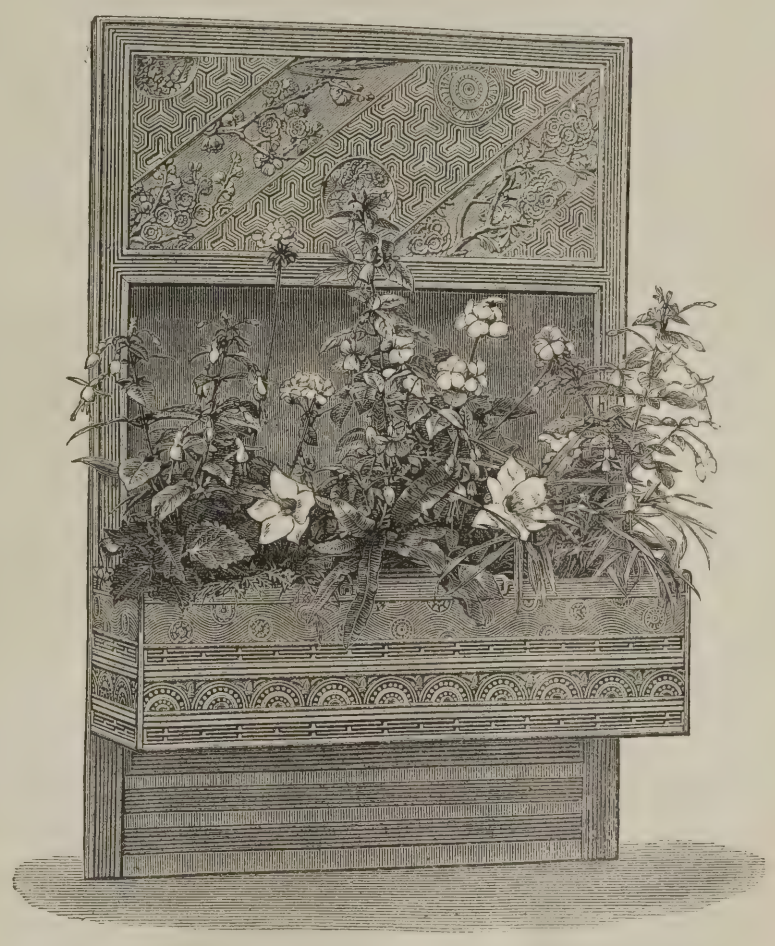
2594.—**Grubs in Carrots.**—The white maggot complained of is at times very troublesome, but yours appears to be an exceptionally bad case. The only remedy likely to be at all effectual is lime water. Give the plantation two thorough soakings at an interval of twelve hours, and then another twenty-four hours afterwards. Lime water is one of the most effectual destroyers of vermin that we possess, and its use is highly beneficial to all growing crops. Another year procure some good strong soot and mix a goodly portion of it with the soil before sowing the seed. A little lime or wood ashes, or both, may also be added thereto. Grubs of all kinds dislike such ingredients, and if a free use is made of them the grubs will give but little trouble. Soot is one of the best manures for Carrots; it gives substance to the root and colour to the foliage, without too much stimulating the latter into rank growth.—J. Cornhill, *Byfleet.*

2590.—**Roses not Blooming.**—Gloire de Dijon is naturally a strong grower, and when fresh planted in congenial soil runs away to wood at a rapid rate. When it has become thoroughly established it will in all probability flower more freely. At the same time you may, if you please, pinch out the points of the strong shoots, which will result in the formation of a crowd of laterals, each one of which should give bloom. By stopping the shoots at intervals of a week a succession of bloom will be maintained until late in the autumn.—B.

2522.—**Book on Painting Flowers in Oil.**—There is no book on painting flowers in oil that would be of any service to an amateur. Painting cannot be learned from books, the processes are too varied and complicated, even the amount of pressure put upon the point of the brush changing the touch produced entirely. The best course is to join the classes at a school of art, a list of which is published in the "Art Directory," which can be had from the Department of Science and Art, South Kensington, for 6d., and postage.—Artist.

2583.—**Apples and Pears for Town Gardens.**—The following do well in the neighbourhood of London: Apples—Hawthornden, a very large cooking Apple, ripens in October, and if gathered at the right time will keep well into December; Keswick Codlin, a profuse bearer, ripens in September; Dumelow's Seedling, very similar to a Ribston, keeps till March; Wellington, rather larger, much the same sort; Blenheim Orange and Blenheim Pippin, useful either for cooking or table. Pears.—Easter Beurré and Hardy Beurré do well in almost any season; the former is a very late Pear.

2488.—**Damage Done to Gardens by Cows.**—In the answer of July 10 to the initials "J. R.," under the above heading, it is stated that a person is not held liable for damages done to his neighbour's garden by his cows if such neighbour's fence is in a bad state. I submit that those persons who have cattle, and not those who have not, must provide protection from such trespassing. This has been decided by a court of law. It seems unreasonable to expect that a person who has not cattle should be obliged to provide a fence to keep out his neighbour's.—J. G. [This may be correct, but you have misunderstood the answer you refer to. What was meant to be conveyed was this: Suppose you plant a hedge round your garden, that hedge belongs to you, and you would not expect your neighbour to keep that hedge in order for you, nor be responsible for his cows coming into your garden through your letting the hedge get into a bad state. If your theory be accepted, it would be necessary to have two hedges round the garden instead of one.—Ed.]



Jardinière for Fire-place in Summer.

2594.—**Wireworms in Carrots.**—Our gardener tried the experiment last June of putting a mixture of one-third salt and two-thirds soot on one end of a bed of Carrots attacked by wireworms. It did not injure the Carrots, which proved sound and healthy, while all the rest of the bed was utterly destroyed by the wireworms.—J. M. L.

2582.—**Unheated Glasshouses.**—A glass roof fixed to a wall is certainly a great aid to the successful culture of the Chrysanthemum and the Rose. Both of these plants suffer much from the inclemency of our Eng-

lish climate—the one in the autumn when expanding its blooms, the other in the spring when making its growth. The slight protection of a glass roof is all that is required in order to enable the grower to derive complete satisfaction from their culture. With such shelter the finer kinds of Tea Roses may be grown with every prospect of success, inasmuch as they will be preserved against the extreme cold and vicissitudes of a severe winter. There will be no absolute need to close the ends unless the situation should be very bleak; indeed, for the Chrysanthemum it will be better to leave them open. Both the Auricula and the Christmas Rose will get the shelter that they need at blooming time, but in the case of the Auricula we think that the situation would be hardly cool enough in the summer; the plants would have to be removed to more airy quarters. The florists' varieties of the Fuchsia would do well in such a place, cutting them down in the winter and covering the stools with several inches of protecting material. —J. C.

2574.—**Removing Moss from Stones.**—The most effectual preparation I have found for this purpose is Sutton's garden path clearer. Its simple manner of use very much recommends it, as well as the complete way it keeps the Moss, &c., from growing again. For cleansing greenhouse floors, stone pavings, gravestones, it is invaluable. Particulars may be obtained from Messrs. Sutton & Co., Chemists, Stowmarket, or Messrs. Cornell, Chemist, Ipswich.—A. C.

2594 & 2597.—**White Worms in Carrots.**—I was troubled with white worms in my Carrot bed, and I tried the simple method of sprinkling salt between the rows of Carrots (about three pennyworth to 24 ft. or 27 ft. square) and in a week they had all disappeared. The salt must not be put on thickly, or it will stop the growth of the Carrots, but if put on thinly it will clear the ground of other grubs which will do almost as much damage to the Carrots as the white grub. Any crop may be sown after the Carrots are gathered, as the ground will be thoroughly cleared.—BEN. W. GREEN.

2515.—**Management of a Room Fernery.**—The reason that you do not succeed with your Fern-case is that you keep it too close and over-water the plants. The case should be opened for an hour twice a week or so, and you must remember that plants in a close case do not need nearly so much water as those grown in a free atmosphere, because the water cannot escape; it floats in the form of vapour in the daytime and condenses at night like dew, thus performing the natural functions of rain without a frequent supply from the watering-can. There should also be efficient drainage at the bottom, so as to prevent water from stagnating. FLOROPHILUS.

2523.—**Insects and Mignonette.**—Mignonette is liable to be thus attacked in some soils. Prepare some lime water and water with it several times. This may destroy the enemy. The better way another time will be to hinder its approach, which may be done by mixing a goodly portion of soot with the soil, which will have the effect of imparting vigour to the Mignonette and keeping off the insects. As soon as the plants are fairly above ground, water once or twice with lime water.—J. C. B.

2595.—**Drosera rotundifolia.**—The Sundew grows naturally where the soil is moist, and where good drainage exists. These natural conditions must therefore be imitated as far as possible. Success, we think, would be best attained by planting in Sphagnum Moss, placing the pot in a pan of water in the summer. Keep the plants in a cold frame in the winter, and maintain the Moss at all times in a moist state. —J. C.

2532.—**Blight on Ferns.**—The green fly may be destroyed by dipping the affected plant in tobacco water or syringing them with the same. We cannot say without seeing it what the white insect is—perhaps mealy bug; in which case as the collection of plants is not a large one, we would advise you to clean them with a blunt-pointed stick. Tobacco water is made by pouring boiling water upon common shag tobacco, straining it through a fine cloth. Use it at the rate of 4 oz. to the gallon.—J. C. B.

2593.—**Lilies Unhealthy.**—We cannot account for the Lilies going off in the manner described. Japanese Lilies are this year, as a rule, growing very strong. We should not suppose green fly to be the cause, but you may easily ascertain if such exists by a close examination of the plants. In some soils this species of Lily will not thrive kindly; try them another year in two-thirds peat and one-third loam well sanded, and plant the bulbs in the open air in pure peat, or you may add to it a little leaf-mould.—J. C. B.

2531.—**Propagating Sweet Briers.**—As soon as the foliage falls take off some shoots of the current season's growth, cut them to three eyes, leaving the leaf to the terminal eye only. Prepare a nice piece of soil in a shady situation, where the sun in April and May does not shine fully upon it, by well stirring it and adding to it a good portion of river or white sand. In this insert the cuttings very firmly quite to the leaf, water if dry, and protect in winter with a little litter. Be sure to keep off the sun in the spring, and water when needful.—J. C.

2515.—**Management of a Room Fernery.**—I keep my case closed for weeks, even months, at a time, and find my Ferns grow well. "Annie's" Fernery is possibly in need of new soil. I seldom find it expedient to "doctor" a Fern case which shows green fly and mouldy plants. Have all the plants taken out and cut off the fronds, wash the inside of the case and refill with fresh earth, which can be supplied by any seedsman. When getting the soil, state it is for a Fern case. Before planting the Ferns give them a good washing, and so remove any lurking green fly. Water well after planting, and close up the case for a few weeks. —R. W.

2296.—**Drying Wild Flowers.**—Having dried many hundreds of these, I would recommend instead of blotting paper the paper specially prepared for the purpose (botanical drying paper). Mine is of a greyish colour, more open in texture, and harder to the feel than blotting paper. It dries the plants better and with half the trouble, requiring to be changed less frequently. When it gets damp have a sufficient supply of dry paper ready into which to transfer the specimens.—PED.

2418.—**Collinsia verna.**—About this annual I find the following in a catalogue: "Height, 1 ft.; colour, sky-blue and white; months of flowering, April and May. Collinsia verna is a charming variety, seeds of which must be sown in August as soon as ripe, or they will not vegetate freely." I would advise the present querist, and indeed every amateur who may not have one, to procure a catalogue from some one or other of the large seed growers.—PED.

2508.—**To Make Putty.**—I should advise the writer who wishes to learn how to make putty to procure some at any oil and colourman's. A short time since I glazed a frame, and the putty cost me 1½d. per lb., which is cheaper than making, as it is most troublesome and takes much time; boiled linseed oil is, I believe, the oil used to mix with whitening.—H. S.

2591.—**Roses and Beetles.**—We know of no other effectual remedy than hand-picking. In some places this beetle is very destructive, especially so where much wood exists, for it is there that it appears to breed. We know of a garden thus situated where it would be impossible to grow a Rose at all were not the appearance of this insect watched for, and means taken to keep it under. —B.

2587.—**Roses for North Aspect.**—Gloire de Dijon, Aimée Vibert, John Hopper, Jules Margottin, La France, and Baron Adolphe de Rothschild. Plant in October as soon as the foliage is off.—B.

2592.—**Climbers for Winter Garden.**—Passiflora edulis and princeps, Stephanotis floribunda, Hoya carnosa, Rhynchospermum jasminoides, and Thunbergia lannifolia.—C.

2530.—**Climbers for Cottages.**—If there is space we would plant Clematis Jackmani and an evergreen climbing Rose, such as Leopoldine d'Orleans or Felicité Perpetuelle. The Clematis should be planted in well prepared, richly manured soil, and should be cut back every year early in spring to within 6 in. of the soil.—C.

2533.—**Keeping Roses Fresh.**—We do not think that there is any means of preserving cut Roses fresh for a length of time. If, however, the ends of the flower-stems are cut off daily and fresh water supplied, they will last longer than they otherwise would.—C.

2525.—**Fern Fronds Withering.**—As the Polypodium phegopteris is a Fern requiring abundance of moisture, the only cause for yours damping off is that the drainage is defective. Although it requires a good deal of moisture, it must be percolating moisture. I should advise you to put it in a more free and open compost, consisting of pure fibrous peat with a little fibrous light loam.—FLOROPHILUS.

Goat Moth.—*G. F. C.*—See GARDENING, No. 14, June 14, 1879.

2633.—**Cost of Keeping up a Garden.**—What should be the annual cost of cultivating six acres of land, laid out as follows, viz.: Two acres as lawn and ornamental garden, two acres as kitchen garden, and two acres as meadow? There are two greenhouses and one forcing house.—HORTUS. [This is a most difficult question to answer, as so much depends upon what you expect from your garden, and in what style you wish it kept. Much also depends upon the conveniences at hand to reduce labour as much as possible. Without knowing some of these particulars it would be impossible to give even an approximate estimate.]

2634.—**Camellias Out-of-doors.**—When is the proper time to plant these? and where could I procure suitable plants? Would an eastern aspect suit them?—A LOVER OF CAMELLIAS. [The best time to plant would be in June, just when the plants commence to make growth, or they might, like other shrubs, be planted in September. You can get suitable plants from any good nursery where hard-wooded plants are grown, but in buying, get well-hardened plants, not such as have been forced in heat all their lives. An eastern aspect would not be so suitable for them as a western aspect, inasmuch as the flowers would be more likely to be cut off by frost in spring.]

2635.—**Strawberry House.**—*Publican.*—We should advise a lean-to house with a stair-like stage at the back, leaving a walk along the front. The stage should be within 2 ft. of the glass. You could grow Tomatoes in pots after the Strawberries were done, also French Beans. That is if you have the house well heated. Procure Shaw's "London Market Gardens."

2336.—**Saving Cucumber Seed.**—How long should I allow a Cucumber that I want for seed to remain on the plant? and also how should I ripen and pick the seeds?—NEMO. [The Cucumber must remain on the plant until it is quite yellow, then cut it open and scoop out the seeds, and lay them thinly on a piece of canvas, or in a hair-sieve to dry. The seeds may then be picked out and put in paper till wanted.]

2637.—**Crassulas not Flowering.**—*F. A.*—Plants of this that were bought in flower last year would be better cut down to within 3 in. or 4 in. of the pot. Place them in a rather shady place till they show signs of breaking into growth, then plunge them out-of-doors in the full sun, and take them indoors at the end of September. They will probably then flower next year.

2638.—**Repotting Orange Trees.**—*Jessica.*—These are best repotted in spring just as they commence to make new growth. Pruning should be done in autumn when necessary.

2639.—**Moving Seakale.**—*Constant Reader, Bristol.*—It would not be wise to move old Seakale plants now. Your better plan would be to lift the roots in winter and plant them nearly close together in a cellar, shed, or a frame kept dark. You will then get some early Seakale. In order to make a new bed the quickest plan would be to purchase a hundred roots or so (they are very cheap); or if you cut off the thong-like roots from the old plants when you lift them into 4-in. lengths, and plant them in good land, they will give you a crop the following year.

2640.—**Planting Bulbs.**—*Bulbous.*—The best time for planting Hyacinths, Tulips, and Narcissi is in October. They will thrive in any good garden mould.

2641.—**Flowers Spotted.**—*J. A. K.*—The reason why your flowers have spots round the edges is probably because they do not get air early enough in the day, and water being on the flowers when the sun strikes them through the glass.

2642.—**Club in Cabbages.**—*C. J. J.*—Take equal parts of soot and fine garden soil and mix with water to the consistency of thin mortar. Into this dip the stems of the plants up to the base of the leaves before planting.

2643.—**Renovating Alstrœmerias.**—*M. T.*—The plants having been for some years in the same position, they have probably exhausted the soil. When the tops have died down in autumn, lift the roots which are tuberous, divide them if necessary, and replant in well-drained sandy soil, in which has been worked a liberal quantity of well-decomposed cow or stable manure. During summer a mulching of half-rotten manure is of great benefit to the plants.

2644.—**Berberis Darwini.**—*M. T.*—The fruit of the common Berberry, B. vulgaris, makes a very refreshing preserve largely used in Rouen, but we have no experience of the fruit of B. Darwini for this purpose. We should say it would be equally good.

2645.—**Improving Heavy Soil.**—I have a small garden the soil of which is very heavy, not clay, but a rich black soil. Will any reader kindly say what I shall apply in order to lighten the same?—F. C. [Road scrapings, river sand, or a good dressing of old lime or burnt clay would greatly improve it; so would leaf-mould. Sifted coal ashes might also be used with advantage. If you cannot get any of these, you might light a fire with wood and rubbish; and when well alight, gradually heap some of the garden soil on it until you get a large heap burnt. This will make excellent material for your purpose.

2646.—**Cucumbers Damping Off.**—*J. R. Pemberton.*—See answer 2648. Grass sods which have been in a heap for some time, Grass side downwards, mixed with well-rotted manure and peat, will make a good compost for Cucumbers.

2647.—**Dividing Pansies.**—*Pansy.*—In order to avoid having long straggling shoots when divided, the best way is to cut the plants down nearly to the ground, and work in amongst them a little finely-sifted sandy soil. They will soon throw up young growths, when the plants may be divided. The shoots cut off may be put in as cuttings in a shady border, under a handlight if required.

2648.—**Cucumbers Turning Yellow.**—I have two Cucumber plants in a greenhouse heated with a flue. They have grown well, made a quantity of wood, put forth plenty of false blossom and fruit, which grows to about 2 in. long and then dies off.—J. W. [Remove all

false blossoms from the plants now, and nip out the growing points of all the shoots, when side-shoots will be put forth. As soon as these latter show for fruit nip out their points, leaving one leaf beyond the fruit, and so keep on through the season. A certain quantity of false blossoms should of course be allowed to expand, as these are the male blossoms.]

2649.—**Mimuluses after Flowering.**—I have a fine Mimulus that has just ceased flowering. In what way shall I treat it now? Can I propagate by means of cuttings?—F. C. [If you cut the plant down to within 3 in. of the pot, and place it in a shady position in a frame or on an outside window-sill, it will throw up young shoots from the bottom, which, when 2 in. or 3 in. long, will root readily in sandy soil in a frame, or even in the window.]

2650.—**Propagating Petunias for Next Year.**—*A Novice.*—Shorten back the shoots of one or two of the plants, and they will produce young shoots, which, if taken off with three pairs of leaves and cut with a sharp knife close under the bottom joint, removing also the two lower leaves, will strike readily under a frame or handlight. Eight or ten cuttings may be put into a 6-in. pot half filled with drainage, using sweet, sandy soil. If these be kept clear of frost and damp during winter they will yield plenty of cuttings in spring.

2651.—**Grapes Failing.**—*Romford.*—The berries are imperfectly set. Those you send are abortive, and only contain three stones instead of four. The small ones will never swell; they may just as well be cut off.

2652.—**Blistered Grapes.**—*J. C.*—The Grapes sent appear to have been blistered through the house having been kept closed early in the morning when the sun was out. Give more air. If you cannot open early in the morning have a little air on all night.

2653.—**Vine Leaves Drying Up.**—*S. K.*—If the Vines have plenty of ventilation and water we cannot understand why the leaves and shoots should wither, especially as the Vines are bearing a crop of Grapes. Have some of the shoots been broken in any way?

2654.—**Treatment of Camellias.**—My Camellia flowered well and made new wood, and about two months afterwards again commenced to grow.—C. M. H. [Place it out-of-doors in a light but sunless situation, placing the pot on a slate or some ashes to keep the worms out.]

2655.—**Canterbury Bells not Flowering.**—*F. A.*—We cannot say why a portion of your plants flower and the others do not; probably they will flower later on. Give them a good soaking with manure water occasionally.

2656.—**Poultry Manure for Flower-beds.**—*F. A.*—This is a good manure for flower-beds, but it is best mixed with soil and a little soot. It may be applied as a top-dressing at once or be dug into the soil in spring.

2657.—**Wild White Strawberry.**—I have a Strawberry which appeared a few years back in a bed on my lawn which has a shrub planted in the centre. It has gradually filled the bed, and has no cultivation besides being kept free from weeds. It is quite white and of a peculiar Musky flavour, but its great attribute is that it continually bears fruit from the end of June till cut off by frost. Would it lose these qualities by being properly cultivated?—J. W. [If you take a few of the young rooted runners now and plant them in well-manured soil they will yield larger fruit than the plants in the old bed, which latter, however, may be improved by giving them a top-dressing of sifted manure in autumn, and during summer an occasional watering with liquid manure.]

2658.—**Pruning Apple Trees.**—*Armiger.*—Trees that have had their summer shoots broken off and have again commenced to grow had better be let alone till winter, when the shoots can be cut back to within two eyes of their base.

2659.—**Corn Salad.**—*F. S.*—Sow in rich soil from August to October. Rake the ground previous to sowing, and afterwards, when fit for use, which it will be in winter and spring according to the time it is sown, cut it off close to the ground and wash it. It is used in mixed salads.

2660.—**Statices Losing their Leaves.**—*Chelmsford.*—If the pots they are in are large enough and full of roots, prick off with a pointed stick a little of the surface soil, and give a top-dressing of Clay's Fertiliser and fresh soil, one part of the former to three parts of the latter, or, better still, give them plenty of liquid manure or clear soot water.

2661.—**Roses to Flower in Autumn.**—*Armiger.*—If you cut back the flowering shoots of standard Roses now, they will produce bloomsin autumn.

Hart's-tongue Fern.—*T. A.*—Red spider has evidently been on the leaves. Keep them well sponged with soap and water.

Begonias Losing their Leaves.—*Extortion.*—Over-watering will do this; so will dryness at the roots. Manure water will also cause it if applied too strong or too frequently.

Fuchsias with Curled Leaves.—*St. E.*—The leaves sent appear to have been attacked with aphides. Cut back the affected points or dip them in Tobacco water.

Lily Leaves Eaten.—*F. A.*—There must be a slug or caterpillar about the plant; look under the pots and well examine the leaves.

Gooseberries Bursting.—*Tyro.*—In wet seasons the skins of Gooseberries often burst when the fruit is ripening.

Book on Roses.—Rivers' "Rose Culture for Amateurs," at our office or through any bookseller.

Flower Pots.—We think there is a place in Great College Street near the canal bridge. You should procure flower-pots at any large pottery shop.

Names of Plants.—*Juvenis.*—1, Campanula muralis; 2, Campanula garganica hirsuta; 3, Campanula garganica; 4, Campanula garganica hirsuta; 5, Campanula garganica; 6 and 7, Campanula garganica pallida.——*Cymro.*—1, Hieracium aurantiacum; 2, Achillea Ptarmica fl.-pl.; 3, Tradescantia virginica.——*C. E. C.*—Campanula Trachelium.——*Bradford.*—We cannot name plants from single leaves; send us good specimens and we will do our best.——*Fred Maude.*—The numbers were all obliterated, and the names without numbers we presume will be of no use to you.——*M. E. W.*—1, species of Galium; 2, species of Erica; 3, Erica mediterranea.——*M. S. M.*—Habrothamnus fascicularis.——*A. A., Stafford.*—1, Chrysanthemum Leucanthemum; 2, Campanula Trachelium; 3, Geranium sanguineum.——*M.*—We cannot name Roses.—*H. J. P.*—We cannot name plants from single leaves.

QUERIES.

2662.—**Calceolarias Diseased.**—Can any reader inform me what is the cause of my Calceolarias flagging and dying off? I have had some beautiful Black Sultans which threw up immense heads of bloom, also some Golden Gems, and small brown ones, and the heads and foliage die down and are useless in a few hours. I have pulled them up, but cannot find anything at the root or on the foliage.—CALCEOLARIA.

2663.—**Vegetable Marrows Dying off.**—Will any one kindly inform me how to treat Vegetable Marrows? I have two healthy looking plants just fruiting, but the blight seems to take every blossom as it comes out, and now the foliage appears to suffer. Is there anything to use as a preventive? and is it well to remove all false blossoms?—M. J.

2664. **Improving Lawns.**—Can any one tell me how to improve a lawn? It was laid last autumn; the Grass is very healthy, and grows so fast it is almost impossible to keep it down, but it is meadow Grass, and not that beautiful fine lawn Grass that looks so exquisite. Perhaps there may be some means of improving it.—H. E. P.

2665.—**Rhododendrons not Flowering.**—I have some Rhododendrons which are very weak and wiry, and have not flowered this year. The soil is sandy, and the situation open and exposed to the sea winds. How can I invigorate the trees? Lime trees here are of slow growth; is the soil unsuited to them? and how can they be improved?—W. H. C.

2666.—**Hardy Perennials.**—What kinds of hardy perennials are best to sow now?—W. H. C.

2667.—**Sowing Potato Seed.**—How can I save and plant seed of the Potato?—L. L. D.

2668.—**Uses of Frames.**—To what uses can I put two frames during the winter, in which I have at present Cucumbers growing?—L. L. D.

2669.—**Onion Maggot.**—Can anybody tell me the best method of preventing or destroying this pest? I have tried a mixture of one part soda to three parts salt, but without effect this season, and the Onions are going fast by their ravages.—B. R.

2670.—**Cypripedium barbatum nigrum.**—How should I treat a plant of this that finished blooming about two months back?—L. S.

2671.—**Heating Greenhouses.**—Will any reader kindly tell me the best and cheapest arrangement for heating a small greenhouse (10 ft. by 4 ft. by 6 ft.)? It is placed in the front of the kitchen window, and inside of the window is a cupboard. Could this not be used to contain the apparatus? There is also a gas-pipe close by; could it be used without causing a smell?—LIVERPOOL.

2672.—**Plants on Graves.**—I should be glad for some suggestion as to the proper way of planting. There is a railing on a marble plinth, and a white marble cross at the head. Is Ivy pegged down, or Stonecrop, or any plant of that kind a good and lasting ornament over a grave? All flowering plants can be put in in pots, but I want something that will last through the winter, as if one were not able or present to attend to the grave one's self.—W. R. CROFT.

2673.—**Exhibiting Dahlias and Asters.**—Will someone tell me the best way to exhibit cut blooms of Dahlias and Asters? Would the latter look well in Moss?—ARTHUR.

2674.—**Tulips for Show in April.**—When should Tulips be potted and started for exhibition early in the month of April next year?—ARTHUR.

2675.—**Climbers for Scotland.**—Will some one name the most suitable climbers for covering the front of a house situated in an exposed situation facing south-east in the north of Scotland?—W. S.

2676.—**Drooping Fuchsias.**—Will any reader kindly give me the name of one of the best drooping Fuchsias for a hanging basket for a cottage window?—W. S.

2677.—**Fever Gum Tree** (Eucalyptus).—Can any one inform me how to keep this plant? I had last autumn nineteen fine plants, and only one lived; I find them so very troublesome to put into larger pots. I have had this year six die from moving.—GILBERT.

2678.—**Law Respecting Greenhouses.**—Being a tenant, I got permission from my landlord to put up a greenhouse. I told him I was not going to make it a fixture. I employed a man and had it made, being away from home myself when it was put up. The man I engaged built a wall 18 in. high, and set the house upon this. The framework is fastened together with bolts and screws; it is not fastened in any way to the brickwork. Will some one please say if I was to remove could I take the house with me, or, having built the wall and set the house upon it, it becomes a fixture? Also if I remain would I be allowed to take the house I have built down and put one up of less value?—AN ANXIOUS ONE.

2679.—**Hydrangeas not Flowering.**—Will any reader inform me how to bloom Hydrangeas? I have tried two years and failed. I have been told to grow them as strong and quick as possible, and that would bring them into bloom. I find they make enough leaf, but no bloom. I have several plants now in different stages of growth, and am ready, in fact, to follow any instructions which are likely to lead to any successful results?—J. A. K.

2680.—**Plants to Flower in Winter.**—What plants can I grow to make a good show in my greenhouse in winter? The frost is only just kept out.—C. M. H.

2681.—**Strawberries Placed in Heaps by some Invisible Agency.**—I find in several places in my garden, principally under the shade of Pears and Gooseberry bushes, heaps of a dozen or twenty or more Strawberries with stems attached. The fruit is intact. Can any one suggest what is likely to have conveyed them there?

2682.—**Petroleum Stoves.**—Will any correspondent kindly inform me if it is possible to heat a small lean-to greenhouse, 15 ft. by 9 ft., by means of a petroleum heating apparatus and water pipes, so as to keep out the frost in the winter months? and if so, what is the most desirable apparatus? Also if the stove can burn in the house without injuring the plants? Perhaps some correspondent will kindly give his experience of petroleum stoves.—G. P.

2683.—**Roses on Trees.**—Can any one recommend a good climbing Rose suitable for climbing over the branches of a large Wellingtonia which is dead?—ARMIGER.

2684.—**Eccremocarpus scaber.**—Can any one tell me how to make Eccremocarpus scaber grow rapidly? In the sandy soil of Red Hill the growth is very slow, and by the time the frost comes the plant is only fairly thriving. I made the soil as rich as I could when the seedlings were planted, but that does not seem sufficient; the plants are very healthy, but grow very slowly.—MARCH.

THE HOUSEHOLD.

STRAWBERRIES.

Strawberry Cream.—Pick the stalks from a pint of Strawberries, sprinkle a teacupful of powdered sugar over them, bruise them well with a wooden spoon, and rub them through a fine hair-sieve till all the juice has been taken from them. Dissolve 1½ oz. of isinglass or gelatine in three-quarters of a pint of new milk, add a pint of thick cream and the Strawberry juice, and simmer all gently together over the fire for five minutes. Pour the cream into a damp mould or into glasses, and set it in a cool place till stiff. A few drops of prepared cochineal may be added to improve the colour. If liked, the juice may be drawn from the fruit over the fire or in the oven. When fresh fruit cannot be obtained, half a pint of Strawberry jam dissolved in two tablespoonfuls of water and strained may be used instead. Time, five minutes to simmer the cream.

Strawberry Cream Ice (à la Muscovite).—Pick the Strawberries, bruise them with a wooden spoon, and rub them through a fine hair-sieve. Take one pint of the juice thus obtained, and stir into it until dissolved five ounces of powdered sugar. Dissolve half an ounce of gelatine in very little water, and add this to the juice. Let the basin containing the juice stand upon rough ice, and stir its contents without stopping until they begin to set. Whip a pint of cream, and mix it lightly with the iced Strawberry juice. Put the whole into a hermetically-closing ice-mould. Put a little butter round the opening to keep out the water, and place it in the ice-pail with pounded ice and bay-salt round it at least 3 in. thick. Let it remain until it is thoroughly frozen. When it is to be served, plunge the mould for one instant into a basin of hot water, turn it upside down upon a glass dish, when the ice will in all probability come out in a shape. If, however, it will not come out, dip it quickly into hot water. Time to freeze, about two hours.

Strawberry Jam.—Gather the fruit after two or three days of dry weather when it is fully ripe, but not over-ripe, or it will be flavourless, and may be tainted with bitterness and the elements of decay. Pick the berries, and discard all that are at all unsound. Weigh the Strawberries, and take three quarters of a pound of loaf sugar for each pound of fruit. Put a layer of berries into the preserving pan, then a layer of sugar, and repeat until the pan is a little less than three parts full. Set it at the side of, but not upon, the fire, and keep stirring gently to prevent burning; but be careful not to crush the fruit. Very carefully remove the scum as it rises, and let the jam boil gently until a little put upon a plate will set, or be stiff. Take the pan from the fire, let its contents cool for a few minutes, then pour the jam into jars. Cover in the usual way. The flavou of Strawberry jam depends a great deal upon

the season. When the summer is cold, wet, and sunless, it is difficult to make jam with the real perfume of the fruit, although it may be made to keep by long boiling and an extra allowance of sugar. Time to boil, three quarters of an hour or more. Probable cost, Strawberries, 4d. to 8d. per pound. The fruit can generally be bought cheaper by the peck.

Strawberry Jam, Superior.—Strawberry jam, although very delicious, is, if anything, *too* luscious. If made according to the following recipe, this fault will be corrected. Take the juice of three pints of ripe white or even Red Currants. Put this into a preserving-pan and throw in four pounds of freshly-gathered ripe Strawberries which have been picked and carefully looked over. Let the fruit boil, remove the scum, and add four pounds of refined loaf sugar. Boil the jam quickly until done enough. Put it into jars, and cover these in the usual manner. Time to boil the jam, from thirty to forty minutes.

Strawberry Jelly.—Take quite fresh fruit which has been gathered in dry weather. Pick the stalks from it, put it into a preserving pan (an enamelled one is the best for the purpose), and place it by the side of a clear fire that the juice may be gently drawn from it. As soon as this flows freely, simmer it until the berries appear to collapse, but on no account allow the juice to remain on the fire till it thickens. Pour the fruit upon a well-scalded but dry sieve, and let the juice drain thoroughly from it: strain it through three or four thicknesses of muslin, and weigh it. Boil quickly for twenty minutes, and stir frequently. Take the pan from the fire, and then add very gradually fourteen ounces of coarsely-pounded loaf sugar for each pound of fruit. Let one portion be dissolved before another is added. When all the sugar is dissolved, put the pan again on the fire, and boil the jelly until a little put upon a plate will stiffen. Pour the jelly into small jars, cover these in the usual way, and store in a cool, dry place. Time to boil the jelly with the sugar, a quarter of an hour or more, according to the quality of the fruit. Probable cost, Strawberries, from 4d. to 8d. per pound; less if bought by the peck.

Strawberry Salad.—Take equal portions of Strawberries and Red and White Currants. Pick them, place them in layers, and pile them on a dish. Sprinkle powdered sugar over them, and pour thick cream upon them. The cream and sugar should not be poured on the fruit till the last moment. If liked, other fruits, such as Gooseberries, Cherries, Raspberries, &c., may introduced into the salad.

Strawberry Solid.—Dissolve three quarters of an ounce of isinglass by boiling it in a quarter of a pint of water. Make a pint of cream very hot, and dissolve in it one pound of Strawberry jelly. Add this to the isinglass, and beat the ingredients till they are thoroughly blended and almost cool. Add a spoonful of powdered sugar if necessary. Pour the solid into a damp earthenware mould, as metal would spoil its colour, and when it is stiff it will be ready for use. If Strawberry jelly is not at hand, jam may be used instead, but it will need to be rubbed through a fine sieve to keep out the seeds. Sufficient for six or eight persons. Time, about an hour to prepare.

Strawberry Vinegar.—This vinegar is excellent for flavouring sweet sauces, also a spoonful or two put into a tumblerful of cold water forms a refreshing summer drink. Gather the fruit in dry weather, when it is fully ripe and finely flavoured. Let it be quite fresh. Pick and weigh it, and put it into stone jars or wide-mouthed glass bottles, and over each pound pour a quart of best white wine vinegar. Cover the jars closely, and let the Strawberries infuse in the vinegar for three days. Drain it off, and put it upon fresh fruit. Let this stand three days, and repeat the operation a third time. Drain off the liquor closely, and let it run through a canvas bag dipped in vinegar. Measure it, and stir into it until almost dissolved a pound of sugar broken up small for each pint of vinegar. Put it over a clear fire in an enamelled (not a metal) saucepan, and let it boil gently for five minutes. Pour it out, let it stand twelve minutes, skim it thoroughly, and bottle for use. Time, ten days. Probable cost, 1s. 6d. per pint.

Strawberry Water (a refreshing summer drink).—Take half a pound of finely-flavoured Strawberries, bruise them well in a basin with a wooden spoon, and mix with them four tablespoonfuls of finely-powdered sugar and a quarter of a pint of cold water. Rub them through a fine sieve, and filter what passes through the sieve till it is clear and bright. Wash the dregs in the sieve with a little cold water to prevent waste. Add the strained juice of half a Lemon and a pint of cold water to the liquor, and put it in ice or in a cool place till wanted. Time, about an hour to prepare. Sufficient for about a quart of water.

Strawberry Wine.—A simple method of making Strawberry wine is to add a little Strawberry juice to good flavourless Currant wine. To make it from fresh fruit, bruise three gallons of Strawberries, and pour upon them three gallons of water. Let them infuse twenty-four hours. Strain the liquor through a canvas bag, and add eight pounds of lump sugar, two gallons of cider, one ounce of powdered red tartar, and the thin rind of a fresh Lemon. When putting the wine into the cask a little brandy may be added if liked.

POULTRY.

The Hydro-Incubator.—We have received from Messrs. Christy and Co., 155, Fenchurch Street, a one hundred page book entitled "Hydro-Incubation in Theory and Practice," by Thomas Christy, F.L.S. The book explains all that is known respecting the artificial hatching of chickens, and is compiled by a man who has had much experience on the subject. Every page is full of interest to the poultry farmer, and illustrations and diagrams are introduced where necessary.

Cramp in Chickens.—I always find a cure for this in placing the chicks in new hay put in a box at night, covering the box over with netting or strips of wood, and letting them have dry ashes to run on in the day time.—A. M. T.

Brahmas and Cochins.—I had an expensive sitting of Brahma eggs. Some of the chickens turn out the colour of Cochins. Is this a variety of Brahma or a "take in?" and what is the reason of variation in colour of Brahma eggs? mine are sometimes lighter coloured than usual.—BRAHMA.

Eggs Without Shells.—What is the reason of my fowls laying shell-less eggs? They have plenty of oyster-shells and bones broken up fine.—V. P. B.

Artificial Hatching.—Is it possible to hatch fowls' eggs in a Vinery with a mean temperature of 70°?—NORMANTON. [We should say decidedly not.]

Brahma Fowls.—There are two varieties of the Brahma, the light being white except the hackle and tail feathers, and the dark of dark grey colour.

BEES.

Losing Bees.—Although feeling all-becoming sympathy with your correspondent "Novice" at the loss of a beautiful stock of bees, I could but smile, when, after treating or rather using his bees (by mistake) most cruelly, he pathetically asks: Is this a fair sample of the humane system? I answer most assuredly not. But, first, I cannot conceive upon what pretence he could be stupifying or smothering a stock of bees just on the point of swarming. If "Novice" would derive both pleasure and profit from bees I would advise him, first, to use none but bar frame hives, for I rather expect his stock that he treated so badly was in a straw skep. The box hives are very easily made, particularly if one of the cheap ones are bought as a pattern. There are many variations of the same principle of Woodbury hives, none better, I think, than Abbott's Combination Hive; with such hives the combs may be taken out and examined, honey extracted, a surplus queen brood taken out, for a queenless hive, or any other manipulation required. Next, in order to understand the proper management, I would recommend him to send to Messrs. Abbott, Southall, Middlesex, for a set of their leaflets on bee management, ten or twelve in number. If he gets them, and follows their directions, I think he would escape other disasters with his bees. By the way, his letter is not a bad sequel to the one preceding it by "A.D.," whose advice must lead to the same results (I mean with respect to the fume of the fungus), but "A. D.'s" advice goes farther. As if doubly to ensure similar disasters, he recommends closing the hive when all the bees are inside, and when they are wanted to be got out of the way, and thereby causing the utmost excitement and confusion amongst them; and then alarms them to the utmost by the smoke, causing them to cluster between the combs and thrust themselves into the comb cells, making it almost impossible to throw them out on to a sheet; this "Novice" found to his cost to be the case. But to get the bees out of a skep by this or any other means is, if not impossible, yet very improbable and deceptive if intended to settle the question if there is a queen or not. I can hardly think that "A. D." has ever performed such an operation successfully.—THOMAS LETCHFORD.

Gravel for Aquariums.—Fine gravel and silver sand will do very well for the bottom; put the plants into it. The top will do left open.—W. C. J.

GARDEN BRIDGES.

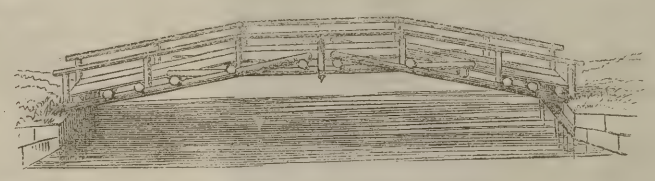
A BRIDGE in the garden is sometimes necessary, especially in connection with ornamental water. Perhaps the best position for a bridge would be at some narrow part of the lake, as remote as convenient, so as to show the principal body of water between the bridge and the place from whence it is viewed, and that, whilst crossing the bridge, the boundary of the water should be completely lost to the eye in various parts, as well by its position as by judicious planting. Thus the extent of a moderate sheet of water might be concealed even from the stroller crossing the bridge. We have frequently seen a bridge placed across the neck of a lake so near to its extremity, as to suggest to the spectator whether it could have been formed for any utility at all, thus destroying the interest which might have been created had its utility been more apparent. Of whatever a bridge may be composed, whether of wood, iron, or stone, or whatever extent it may be, it should be generally horizontal or level across. The effect is inharmonius when it falls each way from the centre. The kind of bridge most suitable for a walk interrupted by a rivulet or brook in a wood or other rural or uncultivated scenery is one simply formed of rude woodwork. When a walk can be carried across a rivulet in front of a cascade or fall, about 10 or 20 yards distant from it, a bridge will add interest to the scenery, and afford convenience to the spectator in viewing the fall. A bridge crossing a rill in a flower garden or other dressed parts of the pleasure grounds may be of iron; but one constructed of Larch rods and poles stripped of their bark, and stained—not painted—though less characteristic, would be generally pleasing. Wood bridges should be made of peeled poles and rods, stained Oak colour, or something similar. Iron bridges should be painted (perhaps bronzed) green or iron colour; never light green. The ends of all bridges must be finished off with trees or bushes. Those upon a large scale should have noble round-headed trees for their decorations, such as the Wych and English Elm, Weeping Willow, Lime, Oak, and Alder; but the best of all is the Wych Elm. All should be more or less associated with loose growing bushes. For smaller bridges in kept grounds the Hemlock Spruce, deciduous Cypress, Tamarisk, Robinia microphylla, Sea Buckthorn, Rosemary-leaved Willow, English Juniper, &c. For small bridges in wild scenery:—Alders, Willows, Thorns, Hollies, Honeysuckles, rambling Roses, Brooms, and Whins are suitable. The annexed illustration, from Mr. Smee's book "My Garden," shows a rustic bridge partly hidden in healthy vegetation springing from the water below, which is far better than having a mere wooden bridge polished and varnished with nothing to relieve its ugliness, as we too often see in gardens. The illustration on next page shows a rustic bridge made without nails. It was exhibited at the International Horticultural Exhibition, St. Petersburg, in 1869. In addition to its rustic and picturesque appearance, it possesses the singularity of being put together without a single nail, bolt or mortice, the whole structure being supported by the beams being made to cross each other in a peculiar manner. It is needless to explain this arrangement, as a glance at the accompanying illustration will be sufficient to show how it is effected. When composed of rustic woodwork bridges might be made less incongruous than they generally are by being covered with climbers. Ivy, for example, would, if well planted in good soil at the foot of the bridge, soon cover the woodwork, and, if kept properly clipped or pruned, form a pleasing feature. The Virginian Creeper, too, might be used with advantage; although its being bare in winter might be a drawback, yet this would be amply compensated for in summer and autumn by its wealth of green and gold-tinted foliage. Honeysuckles, Jessamines, scrambling Roses

RUSTIC BRIDGE IN GARDEN LANDSCAPE.

Some of the Roses, too, are available for such purposes, and by their use rustic bridges, as well as being a necessity, become really an ornament to the garden.

VEGETABLES.

Successful Potato Growing.—Although much has been written on this subject, I venture to send a few remarks which doubtless will interest some of your readers. I must certainly (as one who has had many years' practical experience) dissent from all schemes which assume such voluminous proportions for this one reason, that to grow the Potato well the conditions are such that no professional knowledge is required beyond simple observance of two or three points. First, let the soil be turned up late in autumn, and receive the valuable help afforded by the winter frosts. Second, let this be followed by laying on a good supply of well-rotted manure at the rate of two loads to each pole of ground, say the first week in March. After the manure has been thoroughly incorporated with the soil, proceed to plant the first week in April, and in doing so let every tuber, if practicable, have a healthy sprout of 1 in. Each tuber should weigh about 2 oz. Third, the best sorts for general cultivation are Early Ashleaf, Early Rose, Scotch Champion, and Magnum Bonum. In no case resort to division of tubers, as they are infinitely better for every purpose planted whole. Fourth, when planting, to every 20 poles of ground use 1 cwt. of Potato manure, scattering in the ridges, or laying below and above the Potatoes if a dibber is used. Nothing remains to be done but to await hoeing, and finally lifting the crop. Now this plan is not dubious in its results. I planted April 4 Early Rose and



Garden Bridge built without nails.

Ashleaf, and of the former have already lifted 2 bushels per pole of land, some tubers weighing from 7 oz. to 12 oz.; date of lifting, July 2. The ravages of disease may easily be avoided by the selection of such varieties as come off very early, and the planting of disease-proof main crop kinds such as Magnum Bonum, and particularly Scotch Champion. Considering the importance of the subject, I shall probably again refer to it in the matter of "Choice of Seed Potatoes."—Scrutator.

Potatoes Showing Signs of Disease.—The Potato blight is setting in very fast. I shall adopt the plan I tried last year. As soon as they are touched with the blight cut the tops off and rake them away. I did not have 1 gallon of bad Potatoes out of 40 bushels of American Whites; this year mine are the Snowflake; they are spotted with blight now, and I am cutting away all the tops.—Edward Stone.

Growing Mushrooms.—Any one having the command of a cellar or outhouse may grow Mushrooms to perfection. Get a box about 1 ft. deep, and half fill it with well-rotted manure, completing it with some good compost. Put the spawn about ½ in. deep, well covering with any litter that may be conveniently handy. The Mushrooms will be up in about five or six weeks, and will continue prolific until Christmas.—J. C.

Early Cabbage.—For stiff, loamy soils I have found no Cabbage to equal Excelsior. I sowed the seed the last week in July, and planted out the most forward plants in September, the smaller ones being pricked out for succession in spring. The September plants were a grand crop, and ready for cutting the first week in April, and by cross-cutting the stems there are now from four to six compact heads on each. The flavour is simply delicious, and equal to the most tender Brussels Sprouts. I should mention that the ground was manured with thoroughly decomposed seaweed, which I find most effective with all crops on stiff soils.—W. W., *County Antrim*.

Late Gathering of Rhubarb.—Rhubarb should only be gathered sparingly after this date. I have known plantations seriously injured by clearing off the late crop for wine making. A moment's consideration will assuredly convince any one that a certain amount of foliage is necessary for the healthy development of the buds or eyes for next year's supply.—H.

Sowing Winter Onions.—The first or second week in August is the best period for sowing Winter Onions. A well-drained, well-cultivated plot should be selected, but if in good heart it need not be freshly manured. In addition to the Tripoli varieties, sow a good breadth of Spanish, Globe, and James' Keeping for transplanting early in spring. This is the only plan in difficult situations and seasons to ensure a good crop of large bulbs. South of London the sowing of the three latter kinds I have named may be delayed till towards the end of the month. The Silver-skinned is a good kind also for autumn sowing, as it turns in quickly in spring.—E.

Sowing Winter Spinach.—It is well to make two or three sowings of Winter Spinach at intervals of ten days or so, commencing at the present time. Where the soil is of a heavy retentive character, at least one of the sowings should be made on the driest and warmest spot available, as it not unfrequently happens during a wet or cold winter (unless some such precaution be taken) that a great number of the plants will perish. Ground that has not been deeply dug just previous to sowing is usually less retentive of moisture, and consequently warmer in winter than if freshly and deeply stirred. I am speaking of heavy land only.—E.

Autumn-sown Onions.—In Suffolk these have almost superseded the spring-sown crop, which during the past few years has suffered dreadfully from the ravages of the Onion fly, whilst the autumn-sown crops have escaped with little or no injury from that pest. The ordinary routine of culture is to sow the seed during the month of August, according to locality and situation, usually in beds 5 ft. or 6 ft. wide, and in drills 10 in. or 12 in. apart. If the soil be dry, the seed-bed must be kept moist by watering until the young plants are up, when the only attention required is keeping the surface clean by frequent hoeings until March, when beds of deeply-cultivated and well-enriched soil must be prepared for the reception of the seedlings. We usually spread a good dressing of soot or wood ashes on the surface of the ground, working it in with a rake, and finely breaking the soil; the beds are then marked off and the plants inserted in rows 1 ft. apart, varying the distance in the row according to the size which the variety usually attains. The Giant Rocca and similar sorts may be 1 ft. apart each way, as they grow to a large size. As regards culture, the principal points are frequent surface stirrings and dressings with any rich material, such as fowls' or pigeons' manure, guano, or wood ashes. Any that show signs of running to seed or becoming thick-necked are pulled up for use, and the bulk of the bulbs will be fit for harvesting about the first week in August, for if left in the ground too long, they are liable to start rooting and growing afresh, whereby the keeping qualities of the crop are considerably diminished.—G.

Autumn *v.* Spring Planting of Potatoes.—I think "G. B.'s (Shropshire)" remarks on the autumn planting of Potatoes in Gardening of July 17 liable to cause disappointment to amateurs. From my experience nothing is gained by the practice; even when they prove a good crop (which is an exception) they will not produce more than spring planted (or prove earlier) if spring planting is carefully carried out. In the autumn I thoroughly ripen my Potatoes (greening them), always selecting medium-sized tubers. In February I get a number of shallow boxes about 4 in. to 5 in. in depth; dry soap boxes from grocers will answer the purpose. I then nail a strip in each inside corner of the boxes to stand about 6 in. or 8 in. above the sides of the boxes, so that they can be packed one above the other, and so save space. I then fill them with the Kidneys, carefully placed end upwards, and scatter fine good soil amongst them, leaving each Potato a little room to form roots, and about the middle or end of February I place them in the greenhouse under the stages or anywhere possible. The fire-heat soon starts them into growth, and when about 2 in. high I remove the boxes to a cool place with plenty of light and free from frost, where they get a strong green colour and make plenty of roots, and fit for planting out at any time. Here in Lancashire the second week in March is quite soon enough. I choose a warm south border, give abundance of manure, and plant about 5 in. to 6 in. deep, being careful to do as little damage to the sprits or roots as possible, cutting them out of the boxes in squares, leaving the earth attached, and I get fine crops of good large Potatoes before the end of June, quite as early as the autumn-planted Potatoes, and a better crop, and one that can be depended upon without the risk to be run with autumn planted.—Walter B., *Lancashire*.

BONES FOR THE GARDEN.

In Gardening Illustrated of July 24, Mr. John Hughes asks "how it is that special chemical manures are not more largely employed in our gardens." As the owner of a town garden I reply that it is entirely owing to the exorbitant prices demanded for them. Matters are not quite so bad as they were a few years back, when 1s. tins were generally charged at a rate equal to about £100 sterling per ton for constituents of actual manurial value; still, matters are bad enough for the town gardener even now when he is asked to pay at the rate of about £56 per ton for a special manure if he buy ½ cwt., but even in this case if he require merely one pound then at the rate of £112 per ton, or 1s. per pound. What is needed by town gardeners is a good general manure fit for plant food immediately at a reasonable price.

A town garden has a very short season, ranging from May until October, and, as a rule, manures are needed which will give their full value in that time. Residual values are of little interest to the general run of owners of town gardens who garden for amusement, and who like to reap some reward in a moderate time. Again, they cannot weary themselves with separate manures for separate plants or crops, and it is imperative for them to have a general plant food with the nitrogen combined in a scientific manner. Tins are cheap enough, unskilled labour is not exorbitantly dear, neither are the constituents (magnesia, potash, and phosphate of lime), and the requisite nitrogen can be obtained at a reasonable, although of course a higher, rate; it is therefore a subject of wonder as well as of disappointment to the town gardener that he cannot obtain small quantities of plant food at a reasonable commercial rate.

If Mr. John Hughes can guide them to obtain their needs at a fair market price, he will confer a benefit on all owners of town gardens.

Colvile Browne.

Plant Protectors.—A most useful and inexpensive shade in summer, or protector in winter, I make as follows:—At the grocer's I procure for firewood empty sugar casks, at 3d. each, which prove most useful for several years before breaking up. I first split the tops on firmly to every chine, then saw them all through down one side. At one of the joints, and at the joint exactly opposite, I serve them the same, making two half casks. To prevent their springing open, I stretch a wire across at each

end, making holes with a bradawl for the wire, and just bending the ends to secure it. For a handle I make two holes with the awl about 6 in. apart on the top of the arch, and put a bit of wire through and bend the ends on the under side. They proved most useful last winter; each night and many of the severest days I kept Parsley and other things covered. They are also very useful in shading seedlings after pricking out from the seed bed. I use them cut through the other way for putting over Rhubarb, making the top and bottom serve as lids.—H. S.

ROSES.

Striking Rose Cuttings.—When the buds in the axils of the leaves are fine and plump cut off the shoots you want; take off the leaves and put the shoot into the ground, so that the lowest bud (which should be a nice plump one) is covered with the soil. June and July are the best months, as the buds are then at their best. At the end of some ten days if, as an experiment, you pull up a shoot you will find that the underground stem is swollen, forming a callus, and from this in a few days the roots would have shot out if the cutting had been left in the ground. In from a fortnight to three weeks after first planting the roots are well formed. Marie Baumann, Lamarque, Gloire de Dijon, &c., I have struck in this way by the dozen. Honeysuckles, Fuchsias, Myrtles, Pinks, Virginian Creeper, anything, in fact, that I want cuttings of I rear thus; whenever I pull one cutting out I push another into its place. All, with the exception of the Roses, thrive perfectly well merely transplanted into the open garden or put in plant pots for the sitting-room windows. But the Roses are a very different matter. Some few live and thrive, but only some few, and I shall be very glad to be told how to manage these Rose cuttings through the winter and following spring; the spring appears to be the most critical time.—Mark.

Budding Roses.—Those who have Briers or Stocks should "work" them before the bark gets set. Before operating give the Stocks a good soaking with water, which will cause the sap to flow more freely than it otherwise would do, and use cotton for tying, so as to protect the bud from getting dried up too soon. Roses that have been budded should be well attended to with water, and an occasional sprinkle with the syringe overhead will be of benefit to them.

Watering and Mulching Roses.—These will require plenty of water, and where well mulched the second display of flower will be well advanced by this time, and in some places a good supply of blooms for cutting will be kept up till frost clears all off. Early-started buds should be secured, so as to keep them from getting damaged by high winds and rains. Keep down mildew by means of sulphur, as mildew retards growth very much, and young fresh buds suffer greatly from it. If sulphur be used, it will be required to be syringed off as soon as the mildew is stopped. Tea Rose Duchess of Edinburgh is a valuable addition to our collections; it is a free grower and a wonderfully free-flowering variety. In habit it is similar to Souvenir d'un Ami, growing and flowering quite as freely, and its dark colour will make it much more valuable than that kind for winter forcing. I have forced it and have found it to be most useful for that purpose.—H. G.

Climbing Roses.—When climbing Roses are planted as solitary objects on a lawn they, of course, want something to support them at first; and for this purpose nothing is better or more convenient than four or five thin flat iron rods bent over each other at right angles, with their ends in the ground, so as to form a circular mound about 4 ft. high and 6 ft. through. The Rose tree is planted under the hoops, in the centre of the circle, and as it grows a limb is trained each way to form the foundation of the future plant, and after the first or second year it is left entirely to itself. The supports are soon covered, and a large and natural-looking mound of Roses is the result. We have seen specimens of this kind twenty years old in which the wood had accumulated about 2 ft. or more deep all over the trellis, and yet nowhere was there any dead wood to be seen, owing to the plants throwing out fresh limbs annually, which covered the old ones. The plants, in fact, grow exactly in the same manner as the wild Brier, which, as everybody knows, keeps sending up long shoots from the centre of the plant, increasing its size every year. Those who desire very large mounds may have them just as easily as small ones, and in about as little time, by increasing the size of the iron framework and planting the Roses—as many as they choose—round the sides. This would leave the space inside vacant, and, by keeping the internal surface clipped with a pair of shears, they would have a veritable bower of Roses. This is one way of utilising climbing Roses, and it is a plan by which they can be got to show themselves off to advantage, which they cannot do so well on rockeries and fences, &c., where they are usually trimmed annually to keep them within bounds, and the trimming impairs their appearance. Except against walls and in similar situations, there is no occasion to prune climbing Roses. Left to themselves, they make by far the grandest display; and to insure this, it is only necessary to provide them with a good, deep, strong soil at the beginning, and to let them have a fair amount of light on all sides. Whether planting be carried out with the object above described, or for the purpose of covering naked tree stumps or limbs, or for draping any unsightly object whatever, liberal treatment in the first instance is the main thing. A good soil makes all the difference in time and in the permanent vigour of the tree; and were we desirous of having a great Rose tree (whether it be a common Ayrshire or a Gloire de Dijon, that we expected to produce thousands of blooms in a few years), we should, if the soil were not naturally strong and deep, provide a well-drained pit and fill it with two or three good cartloads of sound loam and manure; thus treated, the result is certain, provided an unrestricted growth be permitted.

House and Window Gardening.

WINDOW GARDENING.

Seeing so much on the above subject, I am glad to give my experience in the management of my window garden, which is admired by all who see it. I have one advantage, viz., I get the sun on my window from eight o'clock in the morning until three in the afternoon. I have four shelves, the bottom one nearest the window (but no fire in the room), and the others stand a little farther away from the window. I have a large frame in the back yard, which gets the sun from eleven o'clock in the morning and remainder of the day. I use no means to heat it, and I have very successfully grown Fuchsias, Pelargoniums, Petunias, Heliotropes, Lilium auratum, Phlox Drummondi, Balsams, Stocks, Asters, Lily of the Valley, Hyacinths, Crocuses, Snowdrops, Tulips, and Wallflowers all as pot plants, and they have given me great satisfaction, as they grow so nice and bushy in the frame, and I do not let them stay in the window long together, or they would soon draw all to the front, and I believe that is the reason one does not see so much window gardening as might be done. Any one could make a turf frame, or even a wooden one would do; an old window would do for the light, allowing it a good fall for the rain to get off, and carefully cutting about 2 in. of the cross ribs off close to the glass at each corner, giving plenty of air on fine days, and well watering and shutting the frame close about five o'clock. In dull weather I only give water to the plants when really necessary. I hope this little information will be of service to some reader. I take a great interest in window gardening, and would like others to give their experience and also the names of plants that can be grown without heat.

John Thompson.

Bolton.

FORGET-ME-NOTS AS WINDOW PLANTS.

Everyone is fond of the Forget-me-not in all its forms, and yet how seldom does one meet with it in small gardens! Many who think Forget-me-nots beautiful in a wild or semi-wild state imagine that they cannot be kept alive in gardens, especially in the neighbourhood of towns; true, they often fail, but the fault lies with the cultivator. People take the common Forget-me-not out of a ditch or a swamp and set it in or on a bed or border of dry earth, and of course it withers up. Other varieties of the Forget-me-nots are also often planted in most ungenial places, as, for instance, right in the eye of the sun, and in soils only fit for making bricks. The roots fail to get a good hold or suitable food, and their tops soon get burnt up. All these causes of failure are easily avoided by growing Forget-me-nots in pots, and by thus rendering them portable a choice or a change of site and of soil may be commanded at any time.

All the Forget-me-nots do well in pots, and some of the prettiest plants for windows may be found in the common Forget-me-not of our ditches. As a bracket plant, or suspended in small vases or bottles of water, too, it is alike interesting and beautiful. All that is needed to get a fine mass of it is to take off a few cuttings, root them in damp soil or in water, and fill a vase, pot, or hanging basket with the young plants as they show flower. A glass basket makes a charming receptacle for the Forget-me-not; it will almost fill it with roots, and profusely cover it with flowering shoots and branchlets. If grown in pots or vases in soil, a mixture of equal parts leaf-mould and loam, or any rough vegetable matter kept sufficiently moist, will answer. As soon as the plants show signs of fading fresh cuttings should be made and started afresh; or the plants may merely be pulled to pieces, the old, exhausted roots thrown away, and the branches already covered with roots formed into new plants by inserting any number of these cuttings, from six to a dozen or a score, into a fresh pot, vase, or basket.

A shady situation, such as a north window, is the best situation for this Forget-me-not during the warm summer months, though earlier and later in the season it will thrive well in a southern or western window. One of the prettiest masses ever seen was suspended from the centre of an east window in a Hyacinth glass, which it filled to overflowing with beauty. I have been thus particular about the culture of the common Forget-me-not, because it is within reach of all, and, being half-aquatic, needs special treatment in regard to water. It must not, however, be thought that water is essential to success in its cultivation; it grows well in damp soil in a shady situation, and is an admirable plant to associate with Musk for clothing and sweetening outlying damp nooks and corners.

It must not be assumed that the other Forget-me-nots are also semi-aquatic. Such fine Forget-me-nots as Myosotis Impératrice Elizabeth, M. azorica cœlestina, M. semperflorens, M. sylvatica, M. alpestris nana cœrulea, M. a. nana alba, and last, but not least, M. dissitiflora, thrive best in soil, and succeed under treatment similar to that given to other plants. For pot culture, M. dissitiflora is perhaps the best of all the Forget-me-nots. The colour, when the blossoms are fully expanded, is a most exquisite blue, and the plant is good in habit. It grows to a height of about 6 in., and spreads out freely, soon furnishing a 4-in. or 6-in. pot. The flowers open in succession from the base of the stem upwards, something like those of the Lily of the Valley; it therefore remains long in bloom. M. azorica cœlestina, an improved variety of a well-known rich dark blue Forget-me-not, is also a plant of great beauty. M. semperflorens is a hardy variety that continues flowering with little trouble from spring to autumn. The white and blue dwarf Forget-me-nots (M. alpestris nana) only grow about 4 in. in. height, and are little gems for pot culture. These might be kept in small pots or even in saucers, as they require but little soil.

The whole of the Forget-me-nots are easily raised from seed or increased by cuttings, but seeds are the only practical mode of acquiring a stock of most of them. They may be sown as soon as they are ripe in spring or summer, or kept till next spring and sown in March or April. If sown at once, the plants will flower the next summer; and, of course, if not sown till next spring, they will not flower till late in the autumn or winter. They may be sown in the open air or in pans or pots, and, being remarkably small, they can hardly be covered too lightly. They should also be sown rather thinly, for if sown too thickly the plants are apt to damp off as soon as they are out of the ground. As soon as the young plants are large enough to handle, they should be pricked off or

potted singly in the smallest thumb pot. If placed under a handlight or cold frame for a time they will make rapid progress, and speedily form useful little plants. Shift as they require it into 2-in. and then into 3-in. pots, in which some of the smaller varieties, such as Myosotis alpestris and M. nana cœrulea, may be flowered, and almost any of the Forget-me-nots grow into excellent window or room plants in 4-in. or 6-in. pots.

The best place in which to grow all these Forget-me-nots, when once they are established, and until they reach the flowering stage, is a partially-shaded, sheltered situation out-of-doors. They grow well in a mixture of rotten leaf-mould with about a fourth part of sand. The drainage should be ample, as most of these Forget-me-nots are semi-alpine plants, and cannot endure stagnant water at the roots, though during both the growing and flowering periods they must not be allowed to become dry. They must not be treated to water so freely as the Myosotis palustris, or they will become unhealthy, and ultimately die. With M. dissitiflora, any garden and house might be enriched with Forget-me-nots the whole year round. Sow a few seeds in July, again in March and May, and a succession of flowering plants would be always available; or, perhaps better still, put in a few cuttings, either in pits or in the open air, from four to half-a-dozen times a year, and this Forget-me-not would be always in flower in the window, greenhouse, or open air.

No plant pays better for a little extra shelter and cultivation than this lovely Forget-me-not. Plants of it potted from the open ground in October or November, and placed in moderate heat —a temperature of 50° or 55°—would be in flower at Christmas. It may easily be had in bloom by little stimulants of this kind indoors till March, at which season it bursts into full beauty in the open air. Its continuance in beauty throughout the summer depends on two things — good feeding and frequent renewal of plants by cuttings or from seeds. By the first only the old plants can be induced to bloom throughout the summer; but, as a rule, younger plants flower more freely. T. F.

Standard Fuchsia with supports covered with German Ivy.

Climbers on Supports.—The Germans have a way of using trailing plants of various kinds which, though not always happily illustrated, is still desirable in some cases. Wherever supports are used for any purpose in the garden, or wire ropes or props, these are wreathed with quick-growing summer climbers, such as the German Ivy, Lophospermum, or Tropæolum canariense. Even the common wild Bryony of our hedges is used gracefully in this fashion to run up strings, or trained round the pedestal of a vase, and so on. In this standard Fuchsia, for example, it was desirable to support the head from all danger from wind; and up the supports accordingly the German Ivy is trained.

Staking Dahlias.—These should always be well secured with stakes to prevent them being blown about and broken by the wind; in giving them this support do not tie them up in the shape of a broom by drawing all the shoots tight to a single stake, for this mode gives them an unnatural ugly appearance, and when strong winds prevail the whole are frequently blown down together. It is a much more effectual and better-looking plan to use four or five moderate-sized sticks for each plant, to which tie the branches out; this has the double advantage of improving their appearance and letting light and air through the plants, which keeps them dwarf and strong. Even for ordinary decorative purposes it is worth while to thin out the branches of Dahlias, for the blooms are developed much finer where this is practised, and the plants necessarily do not get exhausted so soon in the autumn. Water must be given liberally when the ground is at all dry, or they will receive a very severe check; if grown in beds by themselves the whole surface should be mulched over with 3 in. of rotten manure; if in borders amongst other plants, a space ought to be mulched round each Dahlia, as far as the roots extend.

Forget-me-nots for Spring.—Now is the time to make a sowing of these beautiful flowers for spring decoration. Myosotis dissitiflora should be used for early work, and the white and blue varieties of M. sylvatica for later flowering. Though M. dissitiflora is a true perennial, it is much better grown from seed each year than trusting to divided plants. The latter will sometimes stand remarkably well; they did so in a cold, wet, clayey soil in West Middlesex during the past winter, but they cannot always be depended upon; seedlings are more trustworthy. Then there is a very useful summer-flowering Forget-me-not, known as M. semperflorens, which has a particularly durable habit, and which stands well in hot weather; I recently saw this in the neighbourhood of Manchester flowering quite freely in a full sunny exposure. The varieties of M. azorica, and especially that known as Impératrice Elizabeth, make capital summer-flowering plants in pots; and that dwarf but exceedingly beautiful form, M. rupicola, which has the richest blue among all the Forget-me-nots, is a lovely gem for pot-work, but requires some care to have it in all its beauty.—D.

Fine Fuchsias.—There are some Fuchsias which possess an individuality of character both in leaf and flower that renders them valuable as outdoor plants. The fine old F. fulgens may appropriately head the list, with its long orange-red and brilliant carmine flowers; it is a very free-flowering plant, and one which lasts long in perfection. A variety called F. rubra splendens has the same flowers in every respect, but the leaves are smaller and blotched with claret. Then there are the fine old Fuchsia corymbiflora and its light variety, F. virginalis, of which I have a fine plant in full bloom, and very charming it is. In addition I have F. microphylla, the most minute of all Fuchsias, pumila, globosa, Riccartoni, Dominiana, and spectabilis, all as varied in character as they are interesting. They are all the more attractive when mingled with some of the leading modern varieties, and of those I can confidently recommend Sedan, Germania, albo-coccinea, Noblesse, Lustre, and marginata; and for their handsome foliage, Avalanche and Wave of Life. Some of these are so distinct from ordinary Fuchsias as to be doubly valuable on that account. F. Riccartoni is now flowering freely on a west wall in a somewhat cool and shady place in the open air, where it has had no protection for the past three years. —A.

Godetia Lady Albemarle.—This fine crimson Godetia deserves a place in all gardens where a bold, showy flower is desired. It is compact in habit and free-flowering, commencing when it is about 6 in. high, and continuing on in bloom until it is nearly 2 ft. in height. The flowers, which are bell-shaped, are deep crimson with white centres; with me it has been in bloom for six weeks, and promises to keep on flowering for some time to come. It makes an excellent plant for pots on window-sills, provided it gets plenty of sun and water.—R. G.

Hardy Ferns.—I was greatly struck the other day, while passing through a small village a few miles from Penrith, Cumberland, to see such a splendid collection of hardy Ferns on a small rockery situated underneath a drawing-room window. It contained the following sorts: —Adiantum Capillus Veneris, Allosorus crispus, Asplenium Kuta-muraria, Cystopteris fragilis, two or three varieties of Polystichum, Scolopendrium vulgare, and S. vulg. projectum; also Osmunda regalis, the flowering Fern, which makes a splendid addition to a small collection of Ferns; in fact, any one possessing a few should not be without this Fern.—E. Lodge, *Penrith.*

Dwarf Balsams Out-of-doors.—At Bedfont, where Balsams are grown out-of-doors for seed, I noticed lately a very dwarf and compact strain, which looked as if it might prove useful for culture in small pots in windows and greenhouses. As grown in the open ground these Balsams attain a height of about 9 in., and measure about the same in diameter, and are covered with bloom and foliage, and promise to make pretty edging plants for taller-growing kinds. These handsome plants can be produced in 5-in. pots. There are four distinct colours or markings in the flowers—scarlet self, purple self, white-flaked scarlet, and white-flaked purple. The taller-growing, large-flowered kinds bloom most profusely in the open ground, in which they are very beautiful. The colours range through pure white, creamy-white, rosy-white, pink, carmine, scarlet, peach, mauve, purple, crimson, and several blotched and flaked forms, forming about twenty varieties. The culture is of the simplest kind; the young plants are dibbled out into well-prepared ground at the end of May in rows 15 in. apart.—S.

Hardy Plants for Profit.—The great point to be observed is to grow only the very best varieties, so that the seedlings may be recommended as of superior quality. Bedding Violets are in great request, and are of easy propagation. Spiræa japonica and Lily of the Valley are favourite plants for forcing, and if grown liberally will increase rapidly. I would, however, advise as a speciality the culture of the many beautiful forms of Primrose. Those who can get a stock of them will find no difficulty in disposing of them. A large nurseryman lately informed me that he found it impossible to procure enough of the better kinds. The finest varieties being kept true to name and propagated by division, the seed may be saved, and a quantity of young plants raised which would find a ready sale. In the neighbourhood of a market town the bright-flowered, free-growing kinds of Polyanthus would be easily disposed of, as would also nice little tufts of Myosotis dissitiflora, Aubrietia purpurea, Daisies of kinds, Campanulas carpatica, turbinata, and garganica, Gentiana acaulis, &c. Anemone japonica and its white varieties should also be included in the list which may be disposed of in the trade. There are other good things besides those enumerated, but none better or more likely to command a sale.—J.

Trellises above Walls.—The use of walls is so frequent in our gardens that any means of softening their appearance or adding

to their advantage is desirable. In many cases a light trellising above the wall would have great charms; if the wall is low, for example, it may be desirable to raise the surface for climbing plants, as many walls are made too low for the full development of climbers. A light trellis strained above the wall to any desired height allows the climbers to pass up from the wall and to form light wreaths and masses of flowers above it. The hardness and the stiffness of the wall is thus got rid of. The effect of the foliage and flowers is much more light and graceful than on a wall. The plants or flowers can be seen on both sides, which in many cases might be an advantage, and the addition of height is obtained with much less expense than in the case of wall building. The beauty of many suburban gardens would be greatly enhanced if elegantly-clothed trellises were more common. The low walls that are usual necessitate mutilation of the climbers. A greater degree of light for the plants should be added to the advantages mentioned above. We have lately seen a wall in Mr. J. B. Brown's garden at Bromley crested by a wire and netting trellis, and wreathed with large-flowered and sweet-scented Clematis and Roses in a way that produced a beautiful and very natural effect.

GLASSHOUSES & FRAMES.

Nertera depressa.—As regards the raising of this plant the difficulty I experienced was for some time to cause the seeds to germinate, as I used to plant the berries entire, but a friendly gardener advised me to break the skin of the berries, and in each one I found two seeds. The next process is as simple: fill your flower-pots of any size that is convenient with peat and silver sand, and place the seeds on the surface, say 1 in. apart, and keep them well watered. I think it is a mistake to give them too much heat; some of my plants were in a cold box frame the entire winter, and look just as well as those that were in my greenhouse. I should say that every seed must have germinated. The seeds were sown on the 31st of August, 1878, and are now beautifully in fruit.—J. E. D., *Epsom.*

Coleuses in Small Pots.—As an example of what size a Coleus may be grown in a small pot, I would just say that I have at the present time in my nursery a plant in a 4-in. pot struck from a cutting early in April, which measures 6 ft. 4 in. high, has side shoots 19 in. long, and leaves measuring 8 in. long by 5 in. across.—John Green, *Norwich.*

Zebra-leaved Dragon-tree (Dracæna Goldieana).—This is one of the most distinct plants in the whole family of Dracænas. As yet it is comparatively scarce and expensive on account of the difficulty experienced in propagating it quickly. It is, however, an excellent plant of easy structure when established, its tesselated leaves rendering it entirely distinct from any other plant grown in the stove or greenhouse. It will grow well in peat and loam mixed or separate, and requires a temperature slightly higher than that of any ordinary greenhouse. Most nurserymen now have plants of it, but the largest stocks of it we believe are to be found in Mr. Bull's nursery at Chelsea and Mr. Wills' nursery at Anerley.

Hydrangeas after Flowering.—As these go out of bloom they should at once be pruned into shape by shortening the long straggling shoots, after which plunge the plants in an open, sunny situation, that the growth they make may be compact and short-jointed. So managed they will form large globular, symmetrical heads, which, from the thorough ripening the young growth is sure to receive from exposure during the remainder of the summer, will be laden with massive trusses of flowers that are always such an ornament during the early spring months. Any one visiting Covent Garden at that season cannot fail to have been struck with the dwarf well-managed plants of those growing in 6-in. or 8-in. pots, each of which carries an enormous head of bloom, varying from 10 in. to 15 in. through. Those who wish to have plants of a similar size and description should set about their propagation as soon as strong cuttings can be obtained, having the flower-buds already formed and visible at the ends of the young shoots to be severed. Such cuttings can generally be obtained from established plants growing in an open, sunny situation, where, in order to assist them to produce a suitable growth, they should be afforded an occasional soaking with liquid manure, or have the surface soil mulched over by applying it in a solid state. The cuttings should be taken off, so as to preserve about three or four pairs of leaves after the necessary trimming has taken place, which will involve the removal of those from the lower joint to admit of inserting them firmly in the soil in which they are to form root. Single pots of small size are the best in which to strike them, as then they can be shifted on into others without any further check to the leaves or newly-formed roots. In preparing the pots place only a single crock over the hole, and on this a few small pieces of dry crusty manure, afterwards filling up the pots with good fibrous loam in which to insert the cuttings. The pots containing them should then be plunged in slight bottom-heat, under the protection of hand-lights or a glazed frame, in which they should have plenty of air after the first few days to keep the tops cool and prevent the buds from starting, which a close moist heat would induce them to do. In order to keep the leaves fresh and prevent them from flagging, they should be frequently syringed and kept well shaded from the sun till the roots are formed, after which the shading should be gradually dispensed with, and the plants receive their final shift into 6-in. pots. The variegated varieties of Hydrangea are well deserving cultivation for the beauty of their foliage, independent of the fine heads of bloom they produce, almost equalling in that respect any of the green-leaved kinds. When forced early they show much more delicacy of colouring than if grown naturally, and are therefore doubly valuable on that account. Where ornamental-foliaged plants are in request for decorative purposes during the early spring, no better subjects can be had than the two fine forms of the above known as H. aurea variegata and H. argentea variegata. These may be propagated at any time when cuttings can be obtained, and as they are most useful for the ornamental appearance of their foliage, the object should be to get them to a good size as quickly as possible, which may be accomplished by potting them in rich soil, and growing them under glass in a moist atmosphere, where they can get the benefit of a little shade.

Zebra-leaved Dragon Tree Dracæna Goldieana).

Pelargoniums as Basket Plants in Winter.—Hanging baskets in conservatories considerably enhance their attraction. One condition of success in growing basket plants is the careful selection of plants that will really flourish in the strong light and dry atmosphere of such a situation. After trying several experiments, I must give the pre-eminence to the several varieties of Pelargoniums, both for the length of their period of flowering and for the great variety of colour, both in leaf and flower, which they exhibit. About the middle of August last we filled several large baskets with the Pelargonium family. The bottom of each basket was lined with fresh green Moss, and large plants of the Ivy-leaved varieties, such as L'Elégant and Willsi roseum, were planted at the edge, and pegged over the outside of each. The centres were then filled with free-flowering zonals, scarlet, pink, and white, and a few plants of tricolor and scented-leaved varieties. They were hung up out-of-doors under the partial shade of trees for a month until well established, when they were removed to their light, airy, winter quarters, at the top of a large conservatory, where all the autumn and winter they were continually glowing with splendid trusses of bloom. The many beautiful varieties of Ivy-leaved Pelargoniums now in cultivation show to greater advantage in this way than under almost any other circumstances. As soon as the under part of the basket is covered the shoots should be allowed to depend naturally, when their graceful habit will greatly add to the beauty of their showy, but stiff-habited, zonal brethren. The good or bad effects of baskets depend greatly on the graceful and natural manner in which the plants are arranged. Great care must be paid to the watering of all basket plants; they are much exposed to drying currents of air, and therefore suffer sooner from lack of moisture than plants on the floor or stages of the house.—G.

Zonal Pelargoniums.—What plants are really better than the zonal Pelargoniums for the greenhouse? Now that there is such a variety to choose from, there is no difficulty in making a selection of good ones. Throughout the whole summer and autumn you may keep

the greenhouse bright and gay with these useful flowers; and there is nothing better for a bouquet or vase than some fine Pelargonium blooms. It is a good plan to put out the plants for the summer, and then they form good strong specimens before being lifted for the winter. The following are six really splendid ones both for size and colour:—Sophia Berkin, Portia, Titania, Gnome, Mrs. Ward, Mrs. Wright.—W. A. G.

Annuals for Greenhouse in Spring.—There are some few annuals that are very useful as spring bloomers when sown during the months of August and September. The best of these are Schizanthus retusus and its varieties Grahami and Grahami albus. The intermediate Stock is another useful plant in early spring. The little Nemophila insignis makes one of the prettiest basket plants imaginable when grown through the winter under glass. Any one wanting a really fine basket plant will find it in Venidium calendulaceum; this is a very fine annual, and one much too little known. It should be sown in spring, and be planted in a large basket early in the summer, when a grand display of pendent shoots and blossoms will be the result in autumn. Browallia elata and Browallia elata grandiflora are two useful plants for pot culture, and are equally effective at all seasons of the year. By making successional sowings these may be had in flower all the year round. A sowing made about the middle of February in a little warmth will make good flowering plants during May and June, and will help to produce variety at a season when there is not much in flowering except Pelargoniums. Another large sowing should be made about the middle or end of June in a cold frame. These, if grown on without check, will prove very valuable for cutting purposes during the autumn months, and will last a considerable time in bloom, and give a colour that is very scarce at that season of the year. The different varieties of Candytufts—white, purple, crimson, and flesh-coloured—are all useful in autumn. The treatment given to Browallias will suit these, with the exception that more liberal drainage must be given them, otherwise they are liable to damp off during the dull days of autumn.

A FERN-LEAVED HOTHOUSE PLANT.

Paulinia thalictrifolia is one of the most beautiful of plants, and one that cannot fail to become a favourite. It is a native of the southern Brazils, from whence it was introduced to the nurseries of Messrs. Veitch and Sons, of Chelsea. In general appearance it is not unlike a minutely cut-leaved Maiden-hair Fern, and, indeed, so much does it resemble a Fern, that it might easily be mistaken for one. The leaves are of a rich shade of green, and, as the specific name implies, they closely resemble in shape those of some species of dwarf Meadow Rue (Thalictrum). The young branches are clothed with a velvety down of a greenish-chocolate colour, and the woody stems are also tinged with brown. The graceful appearance which the plants have when in a young state is admirably represented in the accompanying illustration. If only required for decorative purposes there should be no inclination to make the plants produce flowers, which are inconspicuous; therefore the main object should be to have plenty of healthy foliage. To secure this, the plant should be grown in a temperature of from 65° to 70°, and if one part of the greenhouse is more adapted to its growth than another, it is the dampest part. After this plant came into the possession of Messrs. Veitch, and before its true value became known, some plants of it were placed in a corner of an old, very damp, warm pit, in which position they grew wonderfully strong, and quite surpassed in vigour and beauty those that were, as was then supposed, placed under more advantageous circumstances, *i.e.*, in drier and lighter parts of other houses. Care is therefore now taken to keep them where abundant atmospheric moisture can be supplied. This plant may be grown to train on a small trellis or to affix to short rafters, but the best mode is to grow it so as to form little well-foliaged specimens. A compost consisting of two parts good substantial peat and one of loam, together with some silver sand, suits it admirably. W.

Honeydew.—In Gardening of June 19 (Query 2354) I quoted two authorities on this subject, one declaring that honeydew is an exudation of the aphis, and the other that it is emitted from the leaves of the plant on which it is found. On the 3rd July two of your correspondents replied, both supporting the insect theory. My own observation convinces me that it does not emanate from the insect, although undoubtedly occasioned by its attacks. I have frequently observed leaves covered with honeydew quite free from and beyond the range of any insects, and therefore physically impossible to be their exudations, although, of course, other parts of the plant were infested by them. Hops, as everybody knows, frequently "go black" from the attacks of aphis and its attendant honeydew, the latter being popularly alluded to as the "sweat" (or natural secretion) of the plant which, in my judgment, is exactly what it is. If so, the sooner Sir J. Lubbock and other writers correct their erroneous impressions the better it will be for science. It is not creditable to the latter that at this time of day there should be any doubt on such a simple matter.—H. D.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

August 9.—Sowing Atkin's Matchless, Shilling's Queen, Dwarf Early York, Cattell's Reliance, Enfield Market, Little Pixie, Early Burn's Cabbage, and Red Cabbage; Walcheren, Early London, and Frogmore Forcing Cauliflower; Tripoli Onion; Stone and other Turnips; Radishes. Potting Cinerarias and Wigandias; finished potting President Strawberries. Planting Endive and Lettuce, latest sown, the latter in trenches; planting Autumn Giant Cauliflower and Cooling's Broccoli; also some broad-leaved Endive. Layering Strawberry runners for planting. Pricking out Wallflowers. Preparing ground for pricking out Stocks. Syringing Azaleas with Gishurst for thrips. Watering Celery every three days. Putting Tripoli Onions in loft. Getting Shallots and Garlic under cover. Looking over wall trees and espaliers and flower beds. Picking off seed-bearing stems from Pelargoniums

Aug. 10.—Sowing Prickly Spinach, Tom Thumb, Bath Cos, All the Year Round, and Victoria Lettuce. Putting in cuttings of scented Geraniums. Layering runners for a new Strawberry bed. Finishing potting Strawberry plants. Shifting Victoria Stocks into 5-in. pots. Left off syringing orchard house, and put plenty of air on all day. Cutting superfluous shoots from Vines. Thinning last-sown Turnips.

Aug. 11.—Sowing Mustard and Cress, Radishes, and Prickly Spinach. Potting Calceolarias and latest Balsams. Cuttings of Pelargoniums; also of Coleus and Pansies. Planting Endive, in deep drills, sown July 11. Planting Lettuce under wall sown July 11; also some Cabbage sown July 1. In the event of failure in the case of July-sown Cabbage, planting some small plants of April-sown Little Pixie, Hill's Incomparable, and Fearnought. Planting some Lettuce sown June 24, and thinning the bed. Tying Dahlias and Peach trees. Staking Chrysanthemums. Nailing Tomatoes. Shifting scented Pelargonium cuttings in 5-in. pots.

Aug. 12.—Potting May-sown Cockscombs in 5-in. pots. Gather Chilies, Gherkins, and French Beans for pickling. Earthing up winter Greens. Cleaning scale off Stephanotis. Fumigating greenhouse for thrips. Stopping Vines. Cleaning up, sanding, and salting walks. Clipping Box edgings. Cutting Laurels. Giving Parsley lime, soot, and guano. Top-dressing Roses in pots. Plunging tree Mignonette. Making border ready for Cabbage, Cauliflower, and Lettuce seeds. Drying herbs. Giving Scarlet Runners guano water.

Aug. 13.—Putting in cuttings of Arabis albida variegata, Pansy (under hand-glass), scented Verbenas, and Pelargoniums. Planting Endive and Parsley. Tying Salvia splendens. Tying up Lettuce. Nailing Tomatoes in orchard house. Netting Jargonelle Pears and late Gooseberries. Repotting intermediate Stocks and Carnations. Removing breastwood from Apple and Pear trees. Cutting down Pelargoniums. Rolling all walks after rain, having first cleared them of weeds. Putting wharf sand on walks. Finishing layering Strawberry runners for planting. Digging land for latest Turnips. Making ground ready for Leeks. Drying Basil, Mint, Thyme, Sage, Hyssop, and Penny Royal.

Aug. 14.—Sowing Syon House Cucumber and Mignonette in pots; also Phlox, Nemophila, Clintonia, Lobelia, and Rhodanthe. Potting Violets; also summer-struck Pelargoniums into 5-in. pots. Planting Rockets. Shifting spring-struck scented Verbenas. Cutting Lavender. Digging first Celery. Gathering Pears, viz., Citron des Carmes and Doyenné d'Eté; and Transparent Apple and Morello Cherries. Plunging Tree Carnations and Cloves. Cutting Portugal Laurels. Making drills ready for Spinach. Keeping Melons from 70° to 75° at night, and from 75° to 80° by day.

Flower Garden.

Herbaceous Plants.—Amongst these there are now in bloom several fine Spiræas, Tradescantias, Campanulas, Asters, Achilleas, Potentillas, Lathyruses, Veronicas, Tritomas, Statices (such as S. latifolia and S. Fortunei), Pentstemons, Phloxes, Stenactises, and others. In order to have fine flowers the shoots should be thinned out a little and small earth basins formed round the roots of each plant for the retention of water. Cut over at about half the length of the stems such plants as have done blooming for the sake of neatness. Many kinds of perennials may yet be propagated from cuttings, and also by means of seeds, which may be either sown in a border out-of-doors or in boxes in frames. Gather all seeds as soon as ripe, dry them, and dress them, and either sow them immediately or keep them till spring.

Bedding Plants.—Such plants as Pelargoniums, Verbenas, Calceolarias, Heliotropes, and similar subjects may now be regarded as at their best; this is therefore a good time for considering what plan of bedding shall be adopted next year. In dry weather plants in active growth will require abundance of water, as well as occasional applications of weak liquid manure; strong-growing plants will require stakes, but as few as possible should be employed. Where Petunias, Verbenas, and similar plants are used as edgings, they should be kept pegged neatly down. Now that the plants in the carpet beds will be growing fast, both knife and fingers must be used freely, so as to preserve exactitude in the pattern, for confusion, as regards design, in this mode of gardening is anything but imposing. Decaying flowers should be removed, seed-pods picked off, and unhealthy or exhausted plants replaced by fresh and vigorous ones.

Pinks.—Pipings which were put in some weeks ago and are now well rooted should be placed out-of-doors. They must now be planted out about 4 in. apart in fine soil, to be replanted again in October. If there be not a sufficient number of plants, it is not difficult to obtain plenty of good side-growths from the strong shoots. Such plants will not be large, but they will produce a few good full-sized flowers. If the space is now vacant where it is intended to put out the plants, it ought to be trenched up and some good rotten manure mixed with it.

Gladioli.—The spikes of these are now showing themselves, and require attention. Stoutish sticks must be put into the ground near the bulbs, but not so close as to injure them, and to these the spikes must be fastened. If the beds are mulched and water is applied when necessary, clear water need only be used; many use guano water or drainings from the manure heap, but as this may aid decay in many of the bulbs, and as the strongest spikes can be produced without its aid, it is better not to use it.

Dahlias.—These are now growing with great vigour, and will require attention. See that traps are set for earwigs, which are very destructive to the blooms; they eat the edges of the yet unopened petals. Bean-stalks inserted between the shoots and the sticks to which the plants are tied form a good hiding-place for the insects; they crawl into them at night, and can be blown out in the morning into a pail of water.

Hollyhocks.—These require much the same attention as Dahlias, such as fastening the main growth to the sticks and removing the side shoots. If eyes can be obtained from these they make excellent plants. Simply take the eye and cut it out with about ½ in. of stem attached; insert these about four or five together in a small pot, using fine soil with a little leaf-mould and sand added to it. See that the stems are fastened to their supports as they progress in growth, else they are likely to snap over during a gale. Mulch round the roots of these as well as Dahlias; both are gross feeders and will take liberal drenchings of manure water.

Pansies and Violas.—Cuttings of these should now be put in. They strike freely in the open air under a north wall, but must be well supplied with water. Pansies, particularly the self-coloured varieties, are very beautiful during spring, but do not flower so long as the Violas; yet, if a succession of plants be kept on hand, by putting in a few cuttings every six weeks throughout the season, from the time growth commences in spring until autumn, uninterrupted bloom may be had; but in the hot summer months they should be grown on the north side of a wall, or they will not produce good flowers, as they do not like exposure to the drying influence of the sun.

Glasshouses and Frames.

Cinerarias should at once be placed in their flowering pots—6 in. or 7 in. in diameter is large enough for ordinary purposes—and, as

the plants are well managed, they will grow therein to a size that will produce fine heads of bloom. They are very subject to green fly, which must never be allowed to get established upon them, or both appearance and vigour will be sacrificed. As soon as the pots are filled with roots they should be regularly supplied with manure water. Never allow them to become cramped at the root before moving them into their flowering pots, or they will not attain their wonted strength and size. Grow them in good loam, with one-fifth of rotten manure and leaf-soil in equal parts added, and as much sand as will keep the soil porous. They do not bear Tobacco smoke well, as it often injures the leaves if applied of sufficient strength to destroy aphides—to free them from which, dipping in a pailful of Tobacco water is the best remedy.

Primulas.—These should also be moved into 6-in. flowering pots. They are somewhat spare-rooting subjects, and do not require a great body of soil to grow in. Drain them well, using soil similar to that used for Cinerarias. Put both in pits or frames, facing northwards, and give air freely, taking the lights completely off the Primulas during the day, but do not allow them to get saturated with rain. In very bright weather a piece of old fruit tree netting placed over them will be useful to break the sun's rays, but will not obstruct the light as a mat would do.

Celosias are amongst the most useful annual decorative plants grown, and at no season do they come in so serviceable as through the late autumn months; the latest sowings will now have made some progress, and attention must be paid as to having sufficient pot-room, as they, in common with all quick-growing plants, if allowed to remain, even for a short time, deficient in this respect, can never afterwards be set to rights. They are naturally disposed to grow higher than often required, to counteract which they should from the first be kept as near the light as they will admit of. Use the syringe regularly to the undersides of the leaves to keep down red spider, to which they are subject.

Table Plants.—Where these are required, there needs to be a continuous supply of young stock coming on, or they soon get too large, and when so used they are very objectionable. Tastes differ somewhat as to the different plants used, but it is generally admitted that the spare-growing, lightest, most elegant plants are the most suitable, amongst which may be reckoned some of the Palms, of which Chamædorea graminifolia, Cocos Weddelliana, C. plumosa, and Geonoma gracilis are the best; add to these, Aralia Veitchi, reticulata, and gracillima; Croton angustifolium, confined to a single shoot; the narrow-leaved Dracænas, such as nigro-rubra, and several of the hybrids of a like character; Pandanus elegantissimus, P. Veitchi, and the variegated P. javanicus; Cyperus alternifolius and its variegated form; Jacaranda mimosæfolia; Reidia glaucescens; and Terminalia elegans. These, and anything else employed for a like purpose, should in all cases be confined to a single stem; anything approaching a bushy habit renders them too heavy, and unfit for use. Such plants of the above as can be increased from cuttings when they get too large may be cut back, and after the shoots have broken and attained a considerable size taken off and struck. Palms can be raised from seed or procured so as to keep up a supply from those who grow them for the purpose. With plants to be used in this way another matter of importance is never to get them in too large pots; 6 in. diameter is quite as big as admissible or necessary, for, with the aid of a little manure water, they can be grown to a size even larger than adapted for the purpose, still retaining all their lower leaves fresh and healthy.

Cool Orchids.—The family of Odontoglossums and Masdevallias are the representatives most worthy of especial consideration in the matter of temperature, but unless where there are a number of houses devoted to Orchids, so as to accommodate those that require different treatment in this respect, it becomes a necessity to grow a good many other kinds with them, some of which are benefited by a few degrees more heat than the plants named like; yet no harm will be done in a compromise of this sort provided treatment is given that will compensate for this. Masdevallias and Odontoglossums in common with other Orchids will not suffer through being subjected to a little more heat than they absolutely need if accompanying it they are grown nearer the glass with a little extra air, as a matter of course using somewhat more atmospheric moisture when the weather is hot and the external air admitted is somewhat dry.

Ferns.—Where there is a house devoted to these plants, or where they have to be grown along with others, there should always be provision made for keeping up a sufficient number of the kinds most useful for decorative purposes in a small state, by annually potting off a number of the seedlings of those that usually come up from self-sown spores, and by sowing the spores of such others alike suitable for use in this way as need to be so raised. The different forms of Pteris serrulata, both crested and plain leaved, are amongst the most hardy and useful plants that can be grown for standing about in greenhouses, intermediate houses, stoves, conservatories, or rooms. So accommodating are they that they will succeed almost anywhere. Adiantum cuneatum is also one of the best, doing well with either a medium amount of heat or in a cool house, and lasting in a presentably fresh condition for some months in ordinary living rooms. A. formosum and A. hispidum will both succeed for a like purpose. Davallia bullata, D. Novæ-Zelandiæ, D. canariensis, Nephrolepis exaltata, and Pteris cretica are all extremely useful for using either amongst flowering plants or in any place where elegant green-leaved subjects are wanted. There are but few private places where the stock of the above might not with advantage be increased. All can be raised from spores or by division. The Davallias can be propagated by division of the rhizomes when the plants are at rest. All these, as well as other Ferns, can be kept in a vigorous healthy state in very small pots provided they are regularly supplied through the growing season with weak manure water; by the use of this, even when the roots are so confined that the growth would otherwise be both weak and yellow in colour, the fronds will come sufficiently strong, possessing the desirable deep shade of green. The hardy Scolopendriums are excellent plants for employing in like manner, and their distinct foliage is an advantage. Such species as Lomaria gibba and L. cycadiæfolia should be annually raised from spores, as they are most serviceable in a comparatively small state. To be successful with the latter variety the fertile fronds should be taken from the plant as soon as ever there is an indication in the coverings of the spore-vessels to rise, otherwise the spores will fall and be lost. The fertile fronds should be broken up into small pieces and scattered over pots or pans filled with a mixture of peat, grit-stone, charcoal, or crocks, with a liberal addition of sand, kept moist, and a sheet of glass laid on the top, placed away from the sun in a little warmth, where they will soon vegetate. Ferns, such as most of the Tree species, that are inclined to get too large in the head for the places they occupy, may, now that their summer crop of young fronds is fully developed, have a considerable number of the old ones cut away. They will also bear washing with Tobacco water to destroy thrips. Should these exist, this is the most effectual method of killing both these insects and their eggs. Where there is scale on Ferns, if it is not kept in check, it becomes an intolerable nuisance, as it spreads with great rapidity to all that stand in contact with, or are overhung by such as are affected with it.

Fruit.

Vines.—It will still be necessary to carefully guard against scalding late Grapes that have not yet passed that critical juncture. Give fire-heat at night, and keep the ventilators 1 in. or 2 in. open in order to prevent condensation of moisture, and this, coupled with free day ventilation, will be found to be a sure preventive of the disease. Houses containing ripe fruit should be kept as cool as possible, and if the weather be sunny a slight shade would tend to preserve the colour of the fruit for a longer period. Check any disposition which early Vines may still show towards making fresh growth by persistent pinching, and see to the renovation of the borders as early as circumstances will permit, in order that the roots may get established in the new soil before the close of the growing season.

Peaches and Nectarines.—Trees from which the crop has been gathered should be regularly syringed, in order to maintain cleanliness of foliage, and if fly be troublesome fumigate with Tobacco paper. Do not hesitate to cut away any straggling shoots that are likely to prove injurious through overlapping others, and which hinder the full action of light and air on the fruiting wood of next season. Keep inside borders well supplied with water, and the trees that are swelling off fruit should have manure water. Soil should be got in readiness for making new borders or renovating old ones, as transplanting and top-dressing should be done as soon as ever there are indications of maturity of growth by the falling of the leaf; there is then no perceptible check as regards fruiting the following season.

Vegetables.

When a choice of two evils occurs it is obviously the best policy to select that which appears to be the less of the two; and as the Potato murrain has now set in, by far the lesser evil will be to at once dig up all kinds that are anything like full sized: even though some may go bad afterwards, it will be better than leaving them in the ground to be entirely destroyed. When the Potatoes are harvested, there will be ample space for all kinds of winter Greens. The planting of Savoys, Kales, Coleworts, and late Broccoli should be completed forthwith, and earlier plantations will now be fit to earth up, a practice at once beneficial both as a protection against wind-waving and as a means of aërating the soil.

A last sowing of Cabbage and Cauliflower may now be made on a warm sheltered aspect to stand the winter. These will make good plants for putting out in spring to succeed the late autumn plantings, the produce of seed sown a fortnight or so ago. The sowing of winter Spinach should not be longer delayed; a deep, moderately rich soil and a dry situation suit it best, and the plants should not be nearer together than 1 ft. each way. We prefer the rows 2 ft. apart, in order that the ground may be the more conveniently hoed and the produce gathered. Onions of the Tripoli and Giant Rocca kinds should at once be sown rather thickly in drills, to be planted out early in the new year. Of course this plan is practised with a view to the utilisation of ground, there being no valid reason against sowing them sufficiently thin, and where they are to mature, except the question of space, which in most gardens is now fully occupied with winter and late maturing autumn crops; such concentration of space is therefore necessary.

Winter Lettuces (Bath Cos), Endive, and Turnips should all now be sown in quantities more or less according to circumstances. Lettuce and Endive may still be planted out with fair prospects of success. If, as often happens, ground for Celery could not be had in sufficient quantity at the proper time, any planted now will come in admirably for soups, and will save the general stock. It should be planted out thickly, and, like Lettuces, that is all the culture which it will require seeing that it is intended for soups only. Earth up the earliest planted Celery; mulch and stake late Peas; cut Globe Artichokes as soon as they are fit for use—even if not required they had better be cut, and when done bearing all the old stems should be removed and the ground loosened with forks or hoes. Remove also the seed stems from Seakale, and thin out the crowns if crowded, in order to favour early ripening. Tomatoes should be encouraged by constantly pinching and training out the shoots, aiming rather at early maturity of a little fruit than a quantity which perhaps may fail to ripen at a later period.

Killing Slugs.—Being much troubled lately with the number of slugs in the garden, and trying several things which did not have so good an effect as I could have wished, I adopted slaked lime powdered finely, at least I got a bag of gas lime (for which I gave 3s., and will last some years in a small garden), and before using exposed, spread out, to the atmosphere for several days and nights to slake, then put into a coarse canvas bag (an old Turnip seed bag I use), secure the neck of the bag with a piece of

thick cord, which make fast to the end of a spud or stout stick, then for a few evenings successively, or very early in the morning, dust anything over that the slugs are taking. I find this method distributed the lime both evenly and quickly. A few minutes each evening suffice to complete the operation, and it is not hurtful to vegetation when well slaked, and slugs dislike it more than anything I have yet tried, and it has much decreased their number. H. S.

FRUIT.

VINES IN POTS.

Although Vines are usually grown in pots for the special purpose of obtaining Grapes earlier than they can be obtained from permanent Vines, or, more strictly speaking, earlier than it would be wise to force permanent Vines, there is no reason why amateurs possessing greenhouses should not grow Vines in pots to ripen their fruit at midsummer or even later. In many greenhouses there is not the convenience for making a Vine border, in which case Vines in pots form the most convenient medium of obtaining Grapes. Moreover, it often happens that the amateur, after having ripened a crop of Grapes, wishes to use his greenhouse for plants, and permanent Vines are consequently in the way, whereas pot Vines may be at once turned out-of-doors. The great drawback to pot Vines, however, is, that they must be bought every year, unless convenience for growing them at home exists; but as good canes can generally be bought for about 5s. each, and these should yield at least 8 lb. or 9 lb. of Grapes of good quality, the investment is not very ruinous. The annexed engraving was taken from a Vine grown in a pot at Berkhamsted by Messrs. Lane & Son, and is a sample of what fine results may be obtained from Vines in pots under proper culture.

A well-grown Pot Vine.

In the culture of pot Vines Messrs. Lane are most successful; they grow about 2000 plants yearly, and they are all grown without bottom-heat, a circumstance of importance as regards their well-being. After one year's growth the canes are cut back to within a few inches of the pots; next year they are started about Christmas, and the bunches which they bear—with plenty of air, light, and room, and abundance of water during the growing season—are the admiration of all who see them. They are grown in 12-in. pots, and at starting time are plunged in a bottom-heat of about 60°, the atmospheric night temperature being about 45°, and the day temperature during sunshine 65°. Instead of being tied to the trellis under the roof of the house at once, as is usually done, they were twisted round stakes inserted in the pots, which has the effect of inducing them to break regularly at every joint. A moist, comparatively low temperature is maintained until the buds burst, when the canes are untied from the stalks and secured to the trellis near the glass, and the temperature gradually increased. Early pot Vines are always grown as near the glass as possible, which has the effect of thickening and hardening the leaves. During the earliest stages of growth strict attention to watering is observed, enough being given to keep the roots moist, but not so much as to saturate the soil. After the fruit is set copious waterings are given, sometimes twice a day; and whilst the berries are swelling rapidly, weak manure water, the result of mixing fresh horse droppings and soot, is liberally given them. Messrs. Lane attribute many failures in growing pot Vines to placing them too near the hot-water pipes, or rather by making the hot-water pipes supply bottom-heat, by which means no regularity of temperature can be maintained, as it is necessary sometimes to have the pipes cold and at others hot, according to the state of the weather; grown under these conditions the young fibrous roots are injured and the crop much impaired. A gentle hotbed of moist plunging material always yields the best results. After the bunches are set the shoots are stopped at three or four joints beyond the bunch, and a little air is left on day and night, which makes the foliage harder and better able to withstand the alterations of cloud and sunshine, which we generally get in spring. A little sulphur is kept sprinkled about the Vineries during autumn as a safeguard against mildew. The soil used for Grape growing here is a heavy, sandy, yellow loam, obtained from the adjoining common.

Keeping Strawberries from Slugs.—"Old Indian" (p. 237) asks for information as to keeping Strawberries clean and at the same time prevent slugs from eating the fruit. My experience is that the best way of accomplishing both purposes is to keep the fruit off the ground, and this I do by making supports for it of bits of lath. A bundle of split laths, 4 ft. long, costs about 3s., and will make a great number of such supports. A lath is cut into four lengths of 1 ft. each; these form the rails. Another is cut into eight lengths of 6 in. each; these form the supports. The rails have ⅝-in. holes bored through them within 1 in. of each of their ends; the supports have corresponding pins worked upon them at one end for insertion into the holes. These pins are about 1 in. long, cut out by "shouldering" the lath. Two, three, or indeed any number of rails may be connected together by having their ends joined over these pins; and, so connected, they can with the greatest ease be applied for the support of Strawberries, keeping them quite clean and effectually protecting them from slugs, which will not climb these posts and rails. An improvement of the post may be made by cutting it 8 in. long instead of 6 in., and sharpening the lower end like a stake for insertion into the ground. This helps to steady the support; but the other plan is effective enough.—J. M.

Rust on Grapes.—Amongst all our Grapes this season all the rusted berries do not exceed a dozen, and previous to thinning not one showed this disfigurement. I am, therefore, of opinion that the scissors, while working amongst the berries, engender rust. Any one who has thinned Grapes will have observed that the scissors soon become quite moist on the part used for clipping. If they are laid down then on a piece of clean wood they will leave a rusty mark, and I am of opinion that the same stain is left on some of the berries, thus producing the disease. Wiping the scissors frequently with a dry cloth keeps them quite clean.—V.

How I Keep Strawberries Clean.—To keep the fruit clean and off the ground, and to preserve them from slugs, I buy a bundle of Fir plaster laths, which costs 1s. per bundle of 90 laths, 4 ft. long, cut them into 1-ft. lengths, and bore a ⅝-in. hole 1 in. from each end; then take some sticks 6 in. long, and make 1 in. at the top round as a peg to fit the hole in the lath, and four laths and four pegs will make a wooden frame to draw all the fruit round its four sides, or if the plants are very large use five laths and five pegs. I have had James Veitch's Strawberries, weighing 2½ oz., supported in this frame quite clean. The laths are about 1 in. broad and about ⅛ of an inch thick. I am indebted to an amateur for this invention.—J. W. H.

Gooseberry Caterpillar.—Over many acres of Gooseberry bushes the caterpillar is now reigning supreme. Although not an unknown visitant by any means, this pest is this year more than usually troublesome, and is clearing off the foliage, not only from Gooseberry bushes, but also from Currants where these come in the way. Our metropolitan growers do not seem inclined to cope largely with the enemy, as in some cases they let the caterpillars alone, and in others employ dressings of soot; but this is productive of but little good, and entirely damages what fruit may be left hanging. Probably the best of all remedies would be to provide children with leather gloves and set them to handpick the bushes, especially in the direction in which the enemy is advancing. Some good would also be done if the bushes were well shaken with stout sticks, and the soil beneath well scraped with hoes, both earth and insects being drawn into the spaces between the lines of bushes, and then well salted and turned in with a spade. All these things would largely help to check the invaders, and the greater the check the less the mischief. Of course, the grower makes the matter one of £ s. d., and if he cannot afford all this labour, or perhaps it is not obtainable, then the bushes must take their chance, and there is abundant evidence that such a course means total disleafing. A large portion of the berries have been gathered in a green state and sold in most cases at good prices. The grower who has allowed Couch and Thistles to choke his bushes finds his fruit small and his returns poor, but the good and clean cultivator, who has the finest berries, is well content.

Salt Water *v.* Weeds on Walks.—Where the hoeing of walks can be easily done, that doubtless is a very good way of keeping them clear of weeds; but in many cases, from the nature of the walk, hoeing is impracticable, and weeding by hand is often so tedious, that the time spent upon it is unprofitable. Recently, to get over some hard walks that could not be conveniently hoed, and which were becoming full of small weeds, the following plan was tried—a very simple one, which has answered effectually in two ways, viz., killing the weeds and saving time:—A water-barrow was filled with water, in which was put a bagful of salt, which was pretty well shaken about in the water till it got a good deal melted; this made the water salt without allowing it to become so dirty as to stop the rose of the watering-pot. This done, the water was taken to where the operation was to be commenced, when the surface was watered with the mixture. Thus managed, a good length of walk is soon gone over, and the plan need only to be tried once to prove its efficiency. Still, the work would require to be done very carefully if there are

Box edgings, as if the water touch them they will share the fate of the weeds. This work can, however, be done with careful hands on walks having Box edgings with the best result. On a dry hot day merely damp the surface with the salt water. This is too much for the weeds to withstand.—M.

The Woolly-headed Thistle (Carduus eriophorus).—This is one of the handsomest of our native kinds of Thistle, and forms noble specimens often from 5 ft. to 6 ft. high. The flower-heads are very large and of a purplish-red colour, and are surrounded on the underside with a dense cottony web, and from this it takes its name. It is a conspicuous plant when mixed with other large-growing plants in the open border, and it has been found specially valuable for producing a sub-tropical effect. In open spots in woods, by wood walks, margins of shrubberies, &c., it is quite at home, as it is quite indifferent as to soil or position.

ANSWERS TO QUERIES.

2591.—**Beetles and Roses.**—The large green beetle to which your correspondent "W. R. Burgess" refers is doubtless Cetonia aurata, one of the most brilliant of our native Coleoptera. Its length is about ¾ in., and it is easily recognised by its shining golden-green colour. This insect is generally found buried amongst the petals of the Roses, but is not generally credited with doing the amount of damage described by Mr. Burgess. The larvæ are usually found amongst the decayed portions of wood, &c., at the foot of trees; but they are also occasionally found in ants' nests. At the approach of winter they penetrate 2 ft. or 3 ft. into the ground, but do not acquire their full size till a space of about three years has elapsed. They then pass through the pupa condition, for which they form a cocoon of wood chips and other materials, which they glue together by a gummy secretion, and in which they secrete themselves. They appear as the perfect insect in the summer. The larva is a soft thick-bodied grub of a greyish white colour, bent in an arch-like manner, but which if straightened would measure about 1½ in. in length. It is narrowest towards the head, and gradually thickened posteriorly. They must be unusually plentiful in the neighbourhood of your correspondent, and the fact of their seeming increase is interesting.

2594 & 2597.—**Maggots in Carrots.**—The little white maggot referred to by "J. M. G.," and also by "Monaghan," as destroying Carrots is the larva of the carrot fly, Psylomyia rosæ. This larva, as described by Kollar, is "cylindrical, pointed anteriorly, like parchment, shining, smooth, bare, pale yellow; the anal joint is rounded, having posteriorly above two black, rather elevated, spiracular plates, the latter having a short point at the end." They are generally found near the extremity of the main root, and work upwards. Miss Ormerod, in a communication to the Entomological Society, recently gave some valuable information. She stated, "On the 19th of June I found the Carrots in my garden perishing under the worst attacks of Psylomyia rosæ that I ever met with. Instead of being simply limited to a number of larval borings towards the extremity of the root, the plants were in some cases killed, in others were destroyed fully half way up, &c., &c. It occured to me that a fluid application I was then experimenting with, known as 'Little's Soluble Phenyle,' of which the ingredients were stated to be a distillation of tar, similar to creosote, and pure oil, and which I had found injurious to insect life whilst beneficial to vegetation, might be of service; and after watering the plants for a few days with it in a dilute state, the application took effect thoroughly. In less than a fortnight the attack had ceased spreading, and some of the infested plants showed signs of recovery; in another week healthy foliage was showing, contrasting with the deep orange-coloured leaves characteristic of the insect attack to the root, and from that time till the 12th of August, when they were raised for examination, sacrificing good and bad together for comparison, they continued to grow luxuriantly with no return of attack of the rust fly. The insect would not be injurious to any other crop put in the same ground; on the other hand, an alteration of crop would deprive the larvæ of their food plant.—W. L. D.

2599.—**Marsh Sundew.**—Patches of the round-leaved Sundew (Drosera rotundifolia) are very pretty if cut out of the bog in which they grow, soil and all, and placed in an ornamental glass saucer covered with a hand-glass. The only treatment they require is for the soil to be kept moist. They are most interesting plants to watch, and at the time the argument was going through the papers as to whether the insects crushed in their leaves benefited them in any way, large quantities were sold in the London streets. In their native haunts, as on the Mosses round Manchester, and notably especially in Studland Bay, Dorsetshire, where they cover larger spaces of ground, in company with longifolia and anglica (equally interesting, but less compact and delicate), they are beautiful beyond description. I do not know if it is generally known what a rare flora is to be found throughout the Isle of Purbeck, at Swanage, Studland, Corfe, and so on. We all know how lovely the wild flowers of Devon are, but those of Dorset are seldom mentioned in books, and I for one had no idea of their abundance until by a most lucky chance I found myself in their midst. In one day's rambling picnic I gathered 150 species, not searching for them in any way, merely picking them as I passed along.—Mark.

Woolly-headed Thistle (Carduus eriophorus).

2626.—**Potatoes Diseased.**—If it is the Potato blight that troubles you—and from your description of the crop it seems to be—it would take no small amount of knowledge to tell you the cause. Although for the past thirty years almost all the scientific and practical horticulturists and agriculturists of Europe have been puzzling their brains to discover the cause of the Potato blight, the problem is yet unsolved. All we know is that the disease is a species of mildew brought on by atmospheric influence—we know not how—and fostered and greatly increased by moisture or dampness of any kind, and consequently that a loose dry soil with a good aspect is best adapted for Potato growing. We know, too, that some kinds of Potatoes which are of a sub-shrubby nature, or which have a crisp, leathery foliage, are less liable to be destroyed by disease than others of a softer nature; and hence that any manure containing phosphates or other substances that would induce a hardy, shrubby growth is the one best adapted for the Potato. Perhaps your land is badly drained, or is a stiff wet clay, which, though it answers for Cabbage and Onions very well, is not at all suitable for Potatoes. If it is undrained, your best way would be to plant the Potatoes on the Irish or lay-bed system; of course if you could have it well drained you should see to it. If your land is wet clay you must, by a careful and constant admixture of coal ashes, lime, sand, &c., lighten it. You did not tell us what sorts of Potatoes you grow, or how you plant them. The following are good, and not very liable to take disease. For first crop—American Early Rose, very productive and good; American Early Snowflake, a fine well flavoured Potato; Grampian, a good hardy cropper; Excelsior, very early and good. Late sorts—Scotch Champion (this is certainly one of the best Potatoes, being productive, large and well flavoured; it should be planted 30 in. apart); Magum Bonum, a productive good sort, but on some lands of inferior quality; Patterson's Victoria, an old favourite; Schoolmaster, one of the best new sorts. If you plant these sorts and substitute the following manure for the rank dung you will find disease less prevalent amongst your Potatoes: Potato manure kanit 1 cwt., soot 1 cwt., sulphur 14 lb. If you cannot obtain kanit, use instead ½ cwt. of salt to 1 cwt. of soot.—D. J. Kane.

2632.—**Gardening in Town.**—At the present time in the new cemetery near Vyse Street (which is in the very heart of the jewellers' district) may be seen in bloom, of a very fair quality, Sweet Williams, Stocks, Pansies, Mignonette, Geraniums, Snapdragons, Lobelias, and several kinds of Lilies. I have also seen in the season Hyacinths, Tulips, Chrysanthemums,

and I might suggest also as an effective border either Thrift, Feverfew, or Candytuft. For climbers I would suggest for the north wall an Ivy, and for the south, Virginian Creeper or Clematis.—G. A. T.

2465.—**Frogs in Greenhouse.**—Frogs are of no value in a greenhouse for the purpose of destroying insects, and it is very doubtful if the toad's presence there is of any greater service. I had about a dozen of them in my greenhouse, thinking they would put an end to a very common pest, the woodlouse, and to my astonishment found them lying quite at home below the toads as a hiding-place. Smoking for air insects, dusting the floors with sulphur or Tobacco powder for ground insects, are the best and speediest methods, thus leaving the rather unpleasant service of Messrs. toad and puddock outside the walls of the greenhouse.—D. C.

2492.—**Grub in Carrots.**—My own opinion on this subject—a subject I have been compelled to give no little attention to—is that if the insect (Psylomyia rosæ) does once put in an appearance in the Carrot bed remedies are little better than useless. However, if the soil be deficient of that property so conducive to the health of this root, great good will be got by applying such in the form of road scrapings, rotten leaves, and all manner of vegetable refuse when preparing for next year's crop Carrot ground should be well trenched, in order that the roots may make an easy passage downward. Salt is the best antidote I know for the worm (and have tried not a few), and can be applied with safety.—D. C.

2506.—**Drying Aquatic Plants.**—Try the same plan as is usually adopted in the case of seaweeds. Float the plant on the surface of water; underneath it place a sheet of paper, not bibulous, and then carefully lift this out with the plant spread upon it. The superfluous moisture may be allowed to drain off, and then the plant, with the paper support, can be placed in the drying paper and press. After the leaves and other parts have become dry they can be moved as easily as those of other plants without any fear of them curling. I send this reply (although I have not had much experience in preserving these kinds of plants) because none has yet appeared.—A. S. W.

2573.—**Ants in Gardens.**—Pouring a little petroleum upon their nest every few days will effectually kill or banish ants. Benzoline is also very effective. Or invert a large empty flower-pot with the hole stopped. The ants will build up into the pot, when it may be lifted with a shovel and dropped into a vessel of water. Camphor water is another good remedy. (Quin's "Garden Receipts.")—Eupteris.

2553.—**Sowing Pansy Seed.**—Sow your seed at once in either a pot or seed-pan in a mixture of turfy loam, leaf-soil, and sand, finely sifted. Plunge in a moderate hotbed and cover with a pane of glass. When the seeds are large enough to handle pot off into 3-in. pots, placing them in a cool frame or greenhouse to stand the winter.—J. C. Burford.

2509.—**Hoya carnosa.**—You should pot at once, or, what is still better, plant in a greenhouse border. Pot in a mixture of good turfy loam, adding a little leaf-mould and sand. This plant, if well drained and in good health, stands a good deal of feeding.—D. C.

2501.—**Roses not Blooming.**—Scoop out a quantity of the soil around the roots without disturbing them; then put in a barrow-load of good turf well rotted and mixed with manure. Make sure that the roots are not in a saturated state.—D. C.

2508.—**To make Putty.**—Take linseed oil, pour upon the whitening, adding a small quantity of turpentine; stir until it arrives at the consistency of a thick paste. Wet your hands in water and knead the paste, and if you find it too soft, roll in some of your whitening, the same as a baker kneads dough.—D. C.

2510.—**Arbutus.**—Dig out a good sized hole; fill up with peat (of course leaving room for your plant in the centre). Beat well. The peat, if not very good, would require a good dash of sand. Be sure that you beat firm.—D. C.

2524.—**Geraniums not Blooming.**—Does your plants run all to wood and foliage? if so, do not give so much stimulant. See that your pot ones are not kept too wet, for Geraniums like rather to be on the dry side. If you wish large trusses to appear, pot in a rather poor soil, but porous; feed strongly with bone dust. Give plenty of air day and night. Keep the atmosphere of the house on the dry side when the plants are in flower.—D. C.

2500.—**Flowers for Button-hole.**—It is taste that is most required in this more than a certain variety of flowers. For my own part I can hardly see a neater button-hole than a small piece of a fancy Pelargonium laid upon a frond of Adiantum. Heliotropes, Statices, Begonias, &c., look very tasty as button-holes.—D. C.

2525.—**Fern Fronds Withering.**—It has probably had too much water, or the drainage may not be good.—Eupteris.

2621.—**Onion Maggots.**—Dissolve quarter of a pound of common salt in two gallons of lime water, and give your Onion bed a good sprinkling with the mixture late in the evening. You will find this an effectual remedy. Tar-water, to be obtained at any gasworks, is a good preventive of maggot. It should be applied to the ground for some time previous to sowing. It is also a good fertiliser.—L. J. Kane.

2517.—**Wireworms in Gardens.**—These are the larvæ of the click beetle. Insert slices of Carrots, Potatoes, or Lettuce stems about 1 in. below the surface of the soil, looking over them every day. When practicable, loosen the surface freely, as birds of all kinds are excessively fond of them. (From Quin's "Garden Receipts.")—Eupteris.

2532.—**Blight on Ferns.**—Lay the pot on its side and syringe the plant, or try Tobacco smoke.—Eupteris.

2631.—**Cut Roses in Water.**—Try putting a small quantity of sal-ammoniac or charcoal in the water.—Eupteris.

2506.—**To Dry Aquatic Plants.**—Take a tray or shallow dish large enough to hold the specimen, spread a sheet of thin paper on it, fill up with clean water; put in the specimen, arrange in a natural manner, cover with another sheet, gently tilt the dish to allow the water to run off without disturbing the specimen; lift both sheets and dry as usual.—J. Makin, *Manchester.*

2685.—**Hydrangeas after Flowering.**—How should a Hydrangea in pot going out of bloom be treated now? Several young shoots have sprung from the roots; should these be divided and potted separately? and when may they be expected to blossom?—Emoorg. [Cut down the stems on which flowers have been produced, and either shake out the soil from the roots and repot, or take cuttings from the young shoots. They should flower next summer.]

2686.—**Manure Water for Wellingtonias.**—*A Subscriber.*—The fact of the Wellingtonia thriving in summer and looking sickly in winter proves that it wants no manure water, but that it wants better drainage during winter. If you could dig a trench 3 ft. deep all round away from the roots, and fill it with brick rubbish, much good might be done.

2687.—**Moss Roses on Walls.**—I have a Moss Rose dwarf trained up a wall, and it has reached the height of 15 ft. or more, and spread as much as that at the side, and up to last year was an admirable tree, but now three-quarters or more is dead wood, and looks very shabby. Shall I cut it all back to the bottom, or cut out all dead wood and leave the rest? [Cut out all dead wood; the plant probably suffered from drought during March, when so many Rose trees were lost.]

2688.—**Rose not Flowering.**—I have a Rose tree which for two years has not flowered, although it did so profusely before that time. The standard has got very thick and knotty, but no Brier has grown from it. It was cut back hard in March or April, and has made a very thick and abundant growth. What can be done with it to make it useful? [Thin out the weak shoots now, so as to let light and sun into the head; and in spring only shorten back a few of the longest shoots, but thin out well.]

2689.—**American Aloes.**—I have in pots some green and variegated American Aloes, and shall be obliged for information respecting their general treatment, and whether they can be kept out-of-doors during the winter? [These require good drainage, a loose compost, such as turfy loam, sand, old mortar, and brick rubbish mixed, and enough water to keep the soil in a moist state. They require the protection of a glasshouse in winter.]

2690.—**Cold Greenhouse and Paraffin Stove.**—Some time ago I was told in reply to a query that if a paraffin stove was placed outside the greenhouse instead of in all would be well. One or two besides myself asked what was meant by this, and if placed outside how the heat would reach the plants, but no answer has been given. Will some one kindly explain?—A. B. C. [Hot-water pipes, of course, must be attached to the boiler over the stove.]

2691.—**Arum Lilies after Flowering.**—*A. B. C.*—Place them outside for a week or two and keep them rather dry; the leaves will then die down and may be cut off, and young growths will appear. Shake the soil from the roots, and divide them if necessary, and plant out in a sunny situation in deep well-manured soil. Lift and pot in the autumn or repot at once, and plunge the pots in ashes, taking them indoors in autumn. Give plenty of water during dry weather.

2692.—**Trollius.**—*W. H. T.*—These are neither expensive nor difficult to obtain. Apply to any nurseryman who makes hardy plants a specialty, such as Mr. Ware, Hale Farm, Tottenham; Messrs. Backhouse & Sons, York; Dickson & Co., Waterloo Place, Edinburgh, &c.

2693.—**Planting Raspberries.**—What is the proper time to transplant Raspberry canes, and what kind of ground is best?—P. H. [As soon as the leaves have all fallen. Light, rich, well-drained soil is necessary for the successful culture of Raspberries.]

2694.—**The Gooseberry Caterpillar.**—These pests generally start upon the new shoots of the year, and, working to the end, completely clear it of leaves. As this is the bearing wood for next year, does it kill the shoot or otherwise prevent its bearing next year?—W. [It certainly does not add to the fruit-bearing capacity of the trees, neither does it entirely render them unfruitful in the coming year. If trees are yearly allowed to be stripped by caterpillars they must decline in health sooner or later.]

2695.—**How to Mix Paraffin with Water.**—How can I mix paraffin with water? It swims on the top of the water, and destroys the foliage as well as the green fly?—F. [Draw the syringe full of water several times and eject it back into the water-can. Do this frequently while you are using the liquid.]

2696.—**The Flowers of a Salvia patens Dropping Off.**—These drop off before they are much more than half developed. Can you suggest a cause for this?—G. M. S.? [Perhaps they are dry at the root.]

2697.—**Dielytra spectabilis.**—Which is the best way to preserve my plants during the winter?—Woolloomooloo. [If in pots, place them in a frame from which frost is excluded, or even in a dry cellar, till they begin to grow, then put them in a window. If out-of-doors, cover the roots 3 in. or 4 in. deep with coal ashes.]

2698.—**Watering Myrtles.**—Does a Myrtle require watering every day? I keep it in a small conservatory.—R. A. M. [If it is dry every day it wants watering every day. Surely you can tell when soil is dry or wet. When you water it give it enough to soak the whole of the soil thoroughly through, and when you observe it getting dry water it again. You may also easily ascertain when a plant is dry by tapping the side of the pot with the knuckles; if a dull sound is given off, it is wet; if a hollow sound, dry. Experiment on a very dry plant and one just watered.]

2699.—**Mushrooms on Lawns.**—I have a plot of Grass which, ten or twelve years ago, was laid down for croquet, but as it is not so used now, and I do not wish to break it up, is there any chance of getting any Mushrooms from it?—W. [In dry positions and in loamy soils Mushrooms may be grown in open situations on lawns. Take a sharp spade and force it into the ground 2 in. or 3 in., withdrawing it without disturbing the Grass; then place it at one end of and at right angles with the first incision and force it into the soil in a similar manner, bending the handle backwards until an opening is made sufficiently large to admit a piece of spawn about 1 in. square. When this is inserted the spade is withdrawn, the turf allowed to fall in its place and be firmly trodden down with the foot; the latter is an important part of the operation. The months of July and August are suitable for performing this operation; the pieces of spawn may be inserted about 3 ft. apart. In soils and situations which are naturally wet this plan would not be successful. When the spawn is found abundantly in an old Mushroom bed, or runs freely through an old heap of stable manure, is the time to secure it for the purpose; or it may be bought in the usual way in the brick form, and broken into suitable-sized pieces, as mentioned above.]

2700.—**Planting Ivy.**—I have a bed made of drain tiles (two tiers), and want to grow Ivy so as to cover them. Which is the best quick-growing Ivy to get? Where can I get it? and when plant it?—R. A. M. [The Irish Ivy will grow the quickest. Get in pots at any good nursery, and plant it in autumn or spring.]

2701.—**Raspberry Canes.**—Am I correct in assuming that suckers thrown up from the root one year produce fruit the next, and then die?—Framboise. [The young suckers bear the fruit the following year. Those that have borne fruit do not always die, but they should be cut out to make room for the young canes.]

2702.—**Azalea Leaves Turning Brown.**—*J. M.*—The leaves are covered with thrips. Lay the plants on their sides, and well syringe them with strong Tobacco water. Place them in a partially shady situation out-of-doors, placing them on slates to prevent worms entering the pots. Syringe them every afternoon with clean water, and repeat the Tobacco water twice a week for two or three weeks.

2703.—**Budding on Different Kinds of Stocks.**—*Enoch.*—Buds or grafts will never succeed on any stock except both scion and stock belong to the same Natural Order. See "Cultivated Plants," by F. W. Burbidge. London: Blackwood & Son.

2704.—**Geranium Cuttings.**—*T. C.*—These strike readily at this time of the year, either in pots or in the open ground. Take cuttings about 4 in. long, and cut them with a sharp knife close below a joint, removing the bottom leaves. Geraniums may be struck from leaves, but such a process is only resorted to in particular cases.

2705.—**Nicotiana longiflora.**—*Vicar.*—This is an herbaceous plant, but is best treated as an annual. Sow in February or March in heat. Prick off the plants, and pot them on as becomes necessary. Plant out-of-doors in deep rich soil, and in a sheltered situation in June. They will flower in August and September.

2703.—**Coat Flowers.**—I have a greenhouse 20 ft. by 9 ft., and I want to devote the whole of it to coat flowers. Will any one help me a little as regards kinds to grow, &c.? The house gets the sun all day, but the country is very cold, but I am well provided with a good boiler, &c., so that I can get plenty of heat.—B. B. B.

2707.—**Roses for Peckham.**—Name two Roses (a Tea and crimson) that will bloom well in Peckham; situation fairly open.—H. P. C. [Gloire de Dijon and General Jacqueminot.]

2708.—**Mule Pinks and Clove Carnations.**—Can Clove Carnations and Mule Pinks be propagated by cuttings as well as layers? if so, kindly give some instructions as to best time and mode of doing it.—C. W. [Take cuttings in August or September about 2 in. long, cut close under a joint, and split the joint across the bottom with a sharp knife. Insert in sandy soil round the sides of small pots, and plunge in ashes in a frame kept close and shady.]

2709.—**Brompton Stocks.**—Kindly explain the treatment of Brompton Stocks from seed onwards; and will they stand winter in the open without protection?—H. P. C. [Prick them 1 in. apart into shallow boxes of sandy loam when large enough. Place them in a sunny position in the open air or in a frame, taking the lights off except in stormy weather. Pot into 3-in. pots when they become too thick in the boxes, and by the end of September a portion may be planted out, keeping the remainder in a cold frame all winter to plant out in spring should those planted out suffer from the weather.]

2710.—**Early Vines.**—My Vines were started last year the first week in November, and the Grapes were all cut by the middle of May. Now the leaves are nearly all off, and some of the Vines are starting again—some of the fruit-buds and laterals. Should they be pruned at

once? They have had plenty of ventilation, are planted inside, and have not been lowered from the roof. Which would be the best way to manage them?—DEVONIAN. [Prune ripened shoots which bore the fruit back about half their length, and throw the house open night and day.]

2711.—**Propagating Carnations.**—What is the proper time to make cuttings of Carnations?—C. C. [From now till September, or in the spring. A frame is best to strike them in. Use yellow loam and silver sand made firm with the spade or foot.]

2712.—**Keeping Plants in Winter.**—How can I keep some roots during the winter for the next season's flowering, more especially the Geranium, Indian Pink, and Pansy?—S. C. M. [Geraniums may be potted in September and wintered in the window of a warm room. Pansies and Indian Pinks are hardy, and require no such protection.

2713.—**Crassula and Kalosanthes.**—*Crazula.*—The Kalosanthes, sometimes called Rochea, belongs to a genus of Crassulaceæ. K. coccinea and its varieties are identical with Crassula coccinea and its varieties.

Labelling Plants.—*H. E. H.*—You will have no difficulty in keeping your Geraniums separate if you use wooden labels painted white and written with blacklead pencil.

Pansy Cuttings.—*H. E. H.*—These strike readily at this time of year, and will succeed well in a box of moist, sandy soil.

Pansies in Winter.—*A. G. P.*—Pansies are among the most hardy of plants, and need no protection in winter.

Heating Greenhouses and Pits.—*F. H., Leicester.*—We cannot advise you from your description. You had better consult some horticultural builder, or a good gardener in your neighbourhood, or send us a plan.

Edelweiss.—*M. M.*—Apply to Mr. Ware, Hale Farm Nurseries, Tottenham, or Messrs. E. G. Henderson & Son, Pine-apple Nursery, Edgware Road, London.

Mildew on Clematis.—*M. M.*—Well syringe them with soft water in which has been placed a little flour of sulphur.

Greenhouse Plants.—*F. H.*—"Stove and Greenhouse Plants," by B. S. Williams, from the author, Victoria Nurseries, Upper Holloway, London, or from our office.

Structure of Flowers.—*H. P. C.*—Procure "Cook's Manual of Structural Botany," price 1s 2d., post free from our office.

Daddy-longlegs.—*H. B.*—Tipula oleracea.

A Puzzled One.—We really cannot understand your questions. Kindly write them separately and concisely.

A. S. W.—We shall receive your communication with pleasure.

Coal Miner.—If you will ask your questions according to our rules, viz., write each on a separate piece of paper, we will gladly attend to them, but we must decline to answer questions respecting bees, poultry, Strawberries, and Rhubarb all rolled into one.

Names of Plants.—*S. Pearson.*—Echeveria secunda. The offsets may be taken off now or in autumn; an attic is better than a garden frame for them in winter, damp being their greatest enemy.——*R. M.*—We cannot name a Cabbage without seeing it.——*St. R. B.*—Deutzia scabra.——*C. M. S.*——The common Corn Marigold, Chrysanthemum segetum, Chrysanthemum Etoile d'Or may be obtained from Mr. Howard, Nurseryman, Southgate, London, N.——*F. A. B.*—1, Limnanthes Douglasi; 2, Eschscholtzia crocea; 3, Evening Primrose (Œnothera riparia).——*C. J. P.*—It would be impossible for any one to name Begonias (unless they are species or very old kinds), for a packet of seed will sometimes bring fifty or more different kinds.

QUERIES.

2714.—**Clematis Dying at the Point.**—Two Clematises (Rubella and Tunbridgiensis) were planted here last March against an arch and have grown, though not with very strong shoots, to the height of about 7 ft., and there are several buds on them. Within the last few weeks the points of many of the shoots and some of the buds have gone off, getting black at the tips, and presenting such an appearance that one would think they had been touched by frost if there had been a chance of it. I cannot see any sign of a caterpillar or blight, and shall be much obliged if any one can suggest what the plants may be suffering from, and what would stop the mischief.—RUS IN URBE.

2715.—**Melons Rotting.**—What is the cause of Melons rotting at the ends when they reach the size of a cricket ball? They are grown in a cool frame, and the plants are doing excellently.—TREDEGAR.

2716.—**My Failures.**—In gardening, as in all else, we learn by comparing our experience with that of others and I have succeeded in making a plant flourish when the gardener has pronounced that "it will never do with us" simply by change of aspect, situation, or a special preparation of soil, and there is always great pleasure in overcoming a difficulty. The following plants have disappointed me this summer in the herbaceous border, but I shall be glad to try them again if I can get hints for their more successful culture. Meconopsis Wallichi and M. nepalensis, good plants last year, stood the winter well, flowered profusely, and have both died away; so has Papaver nudicaule, and a plant of it did the same last summer, which I then attributed to the wet season. Are these Poppies and Poppyworts only biennials? Two plants of the rare Polemonium confertum wintered and grew fairly, and have died away without apparent cause. Has any one succeeded in making this plant produce immense clusters of deep brilliant blue flowers on stout stems 6 in. in height, as described in catalogues? if so, kindly state soil, aspect, and mode of cultivation. Other Polemoniums do well here; the upper soil is light. Schyzostylis coccinea grows, but never flowers, neither does Ourisia coccinea. Iris cristata and I. iberica only exist. Saxifraga Burseriana looks very sickly. Hypericum Burseri and H. olympicum have died; is the soil too hot, or too full of lime? Any hints from those in whose gardens any of the above really flourish will greatly oblige.—H. C.

2717.—**Chemical Manure.**—Will "F. W. P." kindly say where to purchase sulphate of soda and crude sulphate of ammonia, and the price of both?—R. A. M.

2718.—**Ferns for Shady Corner.**—What kind of Ferns are suitable for growing under glass in a shady corner which the sun does not reach? Also what kind of plants will be best to fill up with, more particularly creepers and hanging plants?—J. W.

2719.—**Rose Eaten by Insects.**—Can any one say what it is that eats half through the young shoots of Tea Roses?—H. B.

2720.—**Thistles in Meadows.**—Can any one tell me how to get rid of Thistles from a meadow? I have five acres nearly covered with them?—TASMANIA.

2721.—**Cucumbers Dying.**—Can any reader inform me what is the cause of my Cucumbers suddenly dying off? In a large house, with sixty plants, which, a month ago, were in a fine healthy condition, and bearing splendid fruit, now are all dead. The roots are all cankered and clubbed. I shall be obliged by any information on the subject; it is a serious loss to me.—P.

2722.—**Rusty Water.**—I have just finished a new house, and no water being obtainable on the site, I was obliged to sink a well about 300 yards distant, and bring it here by means of 1-in. iron tubing, but the water is so discoloured by rust, that we are afraid to drink it. I should feel obliged if any one could furnish me with a remedy (not too expensive), also state if it is unhealthy to drink, or if it would be better to let it run into the soft water tank and pump it up mixed, as I have a large tank for soft water.—SUBSCRIBER.

2723.—**Plants for Greenhouse Walls.**—I am about to wire the back of a house, kept at about 60° to 70° to grow plants behind, as lately recommended in GARDENING, and should be glad of a list of plants suitable to grow in that way and situation.—E. T. B.

2724.—**Cactus turning Brown.**—Can any one tell me the reason why Cactus speciosissima, as I am told is the name (the prickly kind), becomes brown, bare, and cankery towards the root?—C. T.

2725.—**Orange Trees and Jessamines not Blooming.**—Can any one account for healthy plants of Cape Jessamine and Orange tree not blooming? They make strong shoots, but the Jessamine especially is most flourishing without any sign of flower; it was in good bloom when placed in the conservatory three years since. The conservatory is principally cast, and only heated sufficiently to keep out frost; it is high, and gets a little sun from the south at mid-day.—LITTLE COOMBE.

2726.—**Bedding Violas.**—Which are positively the best bedding Violas: blue, yellow, or white?—G. G. K.

2727.—**Edging Plants.**—I have a large lawn round which I put Pyrethrums every year, and it looks very well; but as I am very fond of hardy plants, I thought there might be some such plant that would look as well as the Pyrethrum and not require raising from seed each year. Can any one name me any such hardy plant?—G. G. K.

2728.—**Violas for Continuous Blooming.**—Is it best in order to secure a constant display of bloom to plant the bedding Violas fresh every autumn from cuttings just rooted, so that they may bloom in early spring and all through the summer and winter?—G. G. K.

2729.—**Sea-weeds.**—Will any correspondent favour me with some information as to how I may best prepare, lay, or press fine and other sea-weeds? Having a few, and still desirous of such a collection, would be glad to correspond with any one that would oblige with specimens.—JOS. NEWTON, 55, *Hill Street, Ashton-under-Lyne.*

2730.—**Uses of Ash Berries.**—I have many berries of the Mountain Ash in my garden. Is it possible to make use of them for jelly (I have heard of Mountain Ash jelly), or for decorations at Christmas?—A. B. A.

2731.—**Spots on Rose Leaves.**—Can any reader tell me why one Rose in my garden should have large black spots on the leaves? All the rest are perfectly healthy. What can be done to cure this? The Rose is Edouard Morren, and it has flowered beautifully.—M. M. B.

2732.—**Cypripedium insignis.**—Will some reader kindly give me the general treatment of this plant?—J. R.

2733.—**Club in Cabbages.**—Can any correspondent inform me what is the cause of club in all the Brassica tribe, and the best remedy? Portions of the garden have been in cultivation from one to nine years, deeply dug, and properly manured. The plants club just the same on recently cultivated land as on the older part. It is not only a plant or two clubbed here and there, but whole breadths.—INQUIRER.

2734.—**Cinerarias Dying Off.**—What is the cause and remedy of Cinerarias, seemingly in good health, dropping their leaves suddenly and dying off? Mine are in a cold frame at the back of a north wall, on a bed of ashes, but have already lost several through the above cause.—INQUIRER.

2735.—**Cucumbers Dying Off.**—Will any correspondent kindly inform me the reason of and remedy for my Cucumbers dying off? They come on healthy and well until the fruit gets from 4 in. to 5 in. in length and is thickening, then they wither off. I have one plant in a frame 6 ft. by 3 ft., and give plenty of air and water.—W. M. C.

2736.—**Cement for Glass.**—I have made some cathedral glass fanlights and windows, but find that the glass rattles in the lead to an unpleasant degree at the least shake. There is some kind of cement or putty used in the trade which sets very hard, and not only fixes the glass, but also strengthens the whole frame. Can any one tell me what cement this is, and where to get or how to make it?—S. H. W.

2737.—**Propagating Roses.**—Can any reader inform me of the best way of propagating Roses of all sorts?—J. C., *Burford.*

2738.—**Evergreens for Covering Rustic Work.**—I am erecting some rustic work on a lawn to which my fowls have access. Can any reader suggest some evergreens (quick growing) that poultry will not eat to run over the same?—W. N. G.

2739.—**Treatment of Cyclamens.**—I have a fine lot of Cyclamens which this season have made little foliage, scarce any bloom, many of them several years old, but only made a few leaves. I have them now in a cold frame; several of them died off; some again are making new foliage. How shall I treat them?—C. P.

2740.—**Vegetable Marrows.**—My Vegetable Marrows produce none but male flowers, and one or two have come double. Can any of your readers give a reason? and is there any remedy? I have them on a bed of manure (horse litter), fresh the beginning of the year, and under glass.—C. H. S.

2741.—**Climbing Roses.**—"Mark," who writes on climbing Roses, GARDENING, July 17, 1880 (p. 233), will much oblige "A." if he will say by name that Rose he means which has flowered so well in clusters, and which has surpassed Chinas, Teas, &c.? also what locality he writes from?—D. C. A.

2742.—**Storing Potatoes and Cropping a Garden.**—Will anyone inform me how to store and save Potatoes for seed for next spring? I would also be thankful for advice as to the best manner of planting my garden, which is about half an acre; what crops should be planted early in the spring; and what crops should follow, &c. I may say my land is upon a hill. I have a frame 6 ft. by 3 ft., and another frame 6 ft. square. How can I best utilise these for the above garden requisites? I have never worked a piece of ground before, so that I am totally ignorant how to act.—ALPHONSO.

2743.—**Wintering Plants.**—Will some one kindly inform me what plants I can winter in a cold frame with turf sides 1 ft. thick, and a dry bottom? I want the plants for window decoration. I have no means of keeping out frost by heat, but I think with care I can keep the frost out. My plants are doing well at present in it, and I have a great objection to keeping them in the windows all winter, as they get drawn all to the front, and then they look very unsightly. My stock consists of Fuchsias, Pelargoniums, Geraniums, Petunias, Heliotropes, and hardy Ferns, which I should like to keep alive all the winter. Names of any other plants that would do for window decoration would be thankfully received. I have some seedling Primulas, Cinerarias, and Calceolarias doing very well. Can I keep the two last named until they show bloom in the frame? or must I take them out and put them in the house window on the first appearance of frost?—J. T. D

2744.—**Cyclamens not Growing.**—Last year I raised these from seed and they have formed small corms, but have only one or two leaves on each, and do not make any further growth. I shall be glad to receive any information as to treatment necessary; they were repotted in the early part of this year.—A. H.

2745.—**Moss on Gravel.**—I have a gravelled carriage drive well gravelled two years ago; it is in shade from Laurels and Laburnums. How can I keep a fine green Moss away; it gets constantly covered?—T. V.

2746.—**Herbarium Specimens.**—Is it considered allowable to procure specimens of wild flowers for a herbarium from amongst the "weeds" in a garden? or should they be obtained only from fields, road-sides, &c.?—EUPTERIS.

2747.—**Preservative Solution for Herbarium.**—Corrosive sublimate, 1 drachm, methylated spirit 4 fluid ounces. Is there any need to add carbolic acid? and if so, what is the smallest quantity that would be effectual?—EUPTERIS.

2748.—**Furnishing a Plant Case.**—I am very fond of plants, but am unable to have a house of my own, so think of going in for a plant case. Will some one kindly tell me about the size that would be manageable, depth of soil box, hints as to ventilation, &c.? also please give me a list of plants fit for same, and number suited to the size you may name. I want good plants; out of the common; not Ferns, bulbs, or deciduous ones, but something that will be always there.—R.

2749.—**Annual Perennials, &c., to be Sown Now.**—I have had a heated greenhouse built, which is nearly completed, and have, therefore, facility for preserving seedlings this winter. I saw in one part of Vol. I. it was best to sow annuals, biennials, and perennials in the autumn instead of waiting till spring. Will some one kindly name a few good kinds of each? also a few good florist flowers and edging plants, such as Iresine, Echeverias, Amaranthus, &c.—BEGINNER.

2750.—**Inferior Pelargonium Blooms.**—I cannot get a good truss of bloom of either Pelargonium or Geranium of any sort. The trusses begin to go bad in the centre before the bloom is half up; they seem to damp off in the centre. What is the cause, they have plenty of light and air?—A. B. T.

2751.—**Geraniums Turning Yellow.**—About a fortnight ago I had a beautiful Pelargonium given to me, which I placed in the window (inside the room) as near the glass as I could get it, and gave all the air I could; it appeared to do very well for a few days, and then the leaves began to turn yellow. Thinking it wanted more water, I gave it some every second day, but with no improvement in the plant; so I thought it must want more air, and I put it outside the window, but it gradually gets worse. I turned it out to-day; the drainage seemed all right, but the roots were rather black. What is the matter with it? and what can I do to save it?—A LEARNER.

NATIONAL CARNATION AND PICOTEE SOCIETY.

THE annual show of this society, which took place at South Kensington, July 27, was by many pronounced a good one. The flowers were fairly numerous and of good quality from a florist's point of view. For our part, we give the preference to a large collection of border Carnations shown by Messrs. Veitch & Sons, of Chelsea. This collection was instructive, as showing that really handsome blooms may be obtained in the open air, even planted within the reach of London smoke, and blooms that for any purpose save that of competing with the manipulated flowers of the florist are such as any one with a taste for natural flowers would be delighted with. The following are a few of the kinds shown in the collection alluded to, viz.: Princess Alice, white; Lord Rosebery, rose; Fire-eater, flame colour; Elysian Beauty, delicate pink; Old Crimson Clove; Purple Prince, purple; Susan Askey, white; Crimson Pet, deep crimson. Two yellow Picotees shown by Mr. Ware, of Tottenham, named respectively Miss Wheeler and Chromatella, are well worth culture. In regard to Carnations and Picotees grown in pots, there were some excellent examples shown, but they were, as usual, made hideous by the blooms being wired and collared, and made to stare at one like a "Bones" in the Christy Minstrels. A society of this kind should do much good in promoting the culture of those popular flowers, the Carnations, but this we are afraid it will never do until prizes are offered for flowers grown in the open air and shown in their natural form. This would give amateur and cottage gardeners an opportunity of competing and obtaining prizes which are now swept away wholesale by about half-a-dozen growers (one taking as many as five prizes in one class) experienced in the art of what we call spoiling the flowers, but which they call "dressing."

THE HOUSEHOLD.

HOW TO MAKE SALAD.

THE materials must be secured fresh, and not be too numerous and diverse, must be well cleansed and washed without handling, and all water removed as far as possible. It should be made immediately before the meal, and be kept cool until wanted. Very few servants can be trusted to execute the simple details involved in cross-cutting the Lettuce, Endive, or what not, but two or three times in a roomy salad-bowl; in placing one salt-spoonful of salt and half that quantity of pepper in a table-spoon, which is to be filled three times consecutively with the best fresh olive oil, stirring each briskly until the condiments have been thoroughly mixed, and at the same time distributed over the salad. This is next to be tossed well, but lightly, until every portion glistens, scattering meantime a little finely-chopped fresh Tarragon and Chervil, with a few atoms of Chives over the whole. Lastly, but only immediately before serving, one small table-spoonful of mild French or Italian wine-vinegar is to be sprinkled over all, followed by another tossing of the salad. The uncooked Tomato, itself the prince of salads, may be sliced and similarly treated for separate service, or added to the former, equally for taste and appearance.

But there is another form of salad which is always available, and welcome, too, in any season of the year, viz., the salad of cold boiled table vegetables. An excellent basis may be made of cooked French Beans, dressed as directed in the previous paragraph; for this purpose those preserved in tins may be used; greatly inferior as these are when served hot to the fresh *haricots verts*, they are very acceptable as salad in winter and early spring. The preserved green Haricots *(flageolets)*, similarly treated and added in equal proportion, with a garnish of sliced Carrot, Beetroot, or Tomato, may be arranged not only as a most savoury and wholesome, but even as an elegant dish. Cold boiled Potatoes, Carrots, Turnips, Broad Beans, Peas, Cauliflower, and other greens may all be employed thus, combined and garnished according to the maker's taste, which there is abundant opportunity for displaying. In all cases such salads should be kept very cool, and be dressed immediately before serving in warm weather.—SIR HENRY THOMPSON, *Food and Feeding*.

POULTRY.

Overcrowding Poultry.—Now is the time when nearly all poultry breeders are troubled with a greater number of birds than they can conveniently and comfortably find accommodation for. The old birds are mostly still laying, and there is no wish to part with them just yet, while the chickens, which a short time since occupied very little room, are now growing fast, and, being numerous, they need increased accommodation, and the difficulty is to know what to do. Overcrowding is one of the greatest mistakes a breeder can make, no matter whether cattle, fowls, or small birds are kept. All kinds of disease and sickness are produced, and the birds soon begin to look unhealthy. Their plumage gets soiled and bedraggled, and they have a most miserable and wretched appearance. Besides this, those which live soon stop growing and become stunted and weedy specimens. If a breeder has more birds than he can properly and conveniently keep at any time, he should at once commence either to kill or sell some. At this time the inferior and imperfect or wustrel birds may be killed to make room for the better birds. We are convinced, no matter whether poultry are kept for exhibition or merely for domestic use, the inferior specimens should be got rid of as early as their imperfections become visible. It is no use keeping such birds, as they never pay for their food, and they deprive the better and more promising specimens of the care and attention they so much need. We therefore advise all breeders to kill the wustrels. Keep down the number of your birds, for remember the chickens will still require more room as they get bigger. Dispose of all hens that are over two years of age, and give all possible care and attention to the young birds to get them well forward before the winter months arrive.

AQUARIA.

Stocking an Aquarium.—Will "T. C.," who writes that an aquarium properly stocked will not need the water changing for a year, state what proportion of plants and fish should be in an aquarium—a propagating glass 13 in. in diameter—as the water in mine is now getting very thick? Will it clear itself?—CAMPION DAWSON.

—— "T. C." says that if the vessel or glass is properly stocked the water need not be changed above once in twelve months. Would "T. C." or any other reader kindly say what would be the proper stock for a 12-in. propagating glass? I have one that size containing at the present time two carp, one gold fish, three snails, and several bits of plants, not rooted, but sunk to the bottom, with about one dozen small stones. I keep it in the parlour window, which has a north-east aspect, but the sun is not allowed to shine on it; have had two fish die this last week, but cannot understand the cause. I change the water at least twice a week.—G. A. W.

—— *J. Smith.*—See back numbers of GARDENING, in which will be found much information on this subject.

Making an Aquarium.—*Gold Fish.*—We have published several articles on this subject quite recently

Making a Bell-glass Aquarium.—I have a bell-glass, 12 in. over, of which I wish to make a small aquarium. Will some one tell me how many gold fish, &c., to put in, and the best sorts of plants, and best way to place them? I wish to hang a quick bell-glass over the 12-in. one; this leaves a space open all round; must it be covered up? What food is best for fish?—T. B. T.

Gold Fish Dying.—I have for some years had some gold fish in a pond, which have grown and thriven well. Wishing to increase the number, I procured four small ones from Covent Garden, bringing them home in a regular fish-can, as before. Within four days three have died; these were all bright red; one that was dark is alive and well. I should be very glad if any one could tell me what can be the cause of their dying.—P. PHILLIPS.

—— Place a clean sprig of Box in the water, when, by continually rubbing through and against it, the fish will clean the offensive matter from their bodies.—HARRY MOULTON.

HOME PETS.

How to Keep Doves.—Will some one inform me how to keep doves, their food, habits, and requirements, &c., in a large cage.—J. S.

Scab in Rabbits.—I have a buck rabbit whose mouth and feet are covered with scabs. Can any one tell me of a remedy?—SON OF MAN.

Mopish Canary.—In GARDENING ILLUSTRATED, July 17, "Bluebell" asks about a mopish canary. It is to be feared this canary has asthma or consumption. If a sort of sneezing or croaking cough, it is the former. In either case give him light food, sweet Arrowroot biscuit pounded small, with bruised lump sugar or some sponge cake. Hard-boiled egg, chopped fine, and a very little maw seed, which, with the egg, give morning and evening, the biscuit, &c., any time during the day. Do not let him be without sand and fresh water, but not a bath. Rape and canary seed always. The window should only be open when the sun shines on the cage; do not allow the room to be shut up or close; be careful of a draught, keep him warm, and, if possible, in an equable temperature.—A. P.

Canary Losing its Feathers.—My canary appears to have lost some feathers on his shoulders; he is not moulting; is fed on canary (most), rape, occasionally hemp and maw seeds. He is kept clean, and has fresh food and water daily. Can any one give a reason for it?—HENRY PENNY.

Queen Parrots.—"E. M. H." wishes to know where he can get a queen parrot. He can get a very good one at Mr. A. H. Jamrach's, 218, East India Road, London. I got a pair in 1877, and they have been in an out-door aviary ever since. In 1878 they hatched three young birds, but reared only one of them, which is still in my possession, and which has stood the two last severe winters in an unheated aviary. About a month ago my queen again hatched three young birds, but only one survives, and this, I hope, they will rear. They make no nest, but lay their eggs on the bare ground, at least mine do. They are natives of Australia. If "E. M. H." ever passes through Boston I shall be happy to show him both the parents and the baby parrots.—W. M. COOPER, *Boston*.

GARDENING
ILLUSTRATED.

VOL. II.—No 75. *SATURDAY, AUGUST* 14, 1880. PRICE ONE PENNY.
REGISTERED FOR TRANSMISSION ABROAD

GARDENING IN THE LONDON PARKS.

DURING the next month the public parks will be at their gayest, and those wishing to make notes on plants should visit them during that period. Hyde Park, Battersea Park, and Victoria Park are those most worthy of a visit, but if time allows, Finsbury Park, Regent's Park, and Hampton Court may also be seen with advantage. We are pleased to note that a marked improvement has taken place in some of the London parks during the last few years by the introduction of hardy plants in the place of so many of the tender subjects formerly used. Hardy plants, such as the Gunnera scabra, figured on p. 281, the hardy Aralias, with their glossy-green Ivy-shaped leaves, the Tree of Heaven (Ailantus glandulosa), which forms spreading branches of light green-bronze-tinted leaves, if cut down each year, and the beautiful cut-leaved Sumachs are all taking the places to some extent of such tender plants as those figured on pages 282-3, which only endure for a few weeks in warm sheltered nooks and in exceptionally favourable summers. Tall Larkspurs, Phloxes, Pentstemons, Violas, hardy Fuchsias, &c., now occupy the places formerly allotted to glaring Pelargoniums and other tender plants, and in all the parks there seems at last to be some token of other plants being represented besides those that come under the much abused section called "bedding" plants, and we trust the day is not far distant when real beds and borders of thoroughly hardy plants, which give a profusion of bloom from February to Christmas, will be so arranged that possessors of small gardens and limited means may imitate them with advantage. At Victoria Park, where long borders exist, much has been done in this direction, but much yet remains to be done; but if we may be allowed to draw comparisons, this comparatively new park in the east of London is the most representative one as regards flower gardening of all the London parks. Carpet bedding, ribbon gardening, sub-tropical gardening are well represented, and hardy flower gardening is fast coming to the front, aud some of those crowded beds of Geraniums, Centaureas, Perillas, &c., on the left of the long walk will doubtless some day give way to noble clumps of Phloxes, Pæonies, Larkspurs, and other showy hardy plants. In the long border next the road we noticed a number of the hardy perennial double Sunflowers (Helianthus multiflorus fl.-pl.), Eschscholtzias, Verbena venosa, Snapdragons, Veronicas, Spiderworts (Tradescantias), Irises, Day and other Lilies, Statices, and other hardy plants, which, with a few Sweet Peas and other annuals intermixed, make a display long before the flower beds proper are planted and long after they are cleared.

LONDON PUBLIC GARDENS: VIEW IN ST. JAMES'S PARK.

Some of the mixed beds in Victoria Park are attractive, but rather spoiled by being planted too thickly. We allude to those planted with India rubber plants, Acacia lophantha, Abutilons, Aralias, Cannas, gold-leaved Fuchsias, Erythrinas, &c. The hardy Fennels (Ferulas), with their glossy thread-like foliage, are quite equal to any other plants we saw in the way of fine-foliaged plants, and they only require to be planted once, they being able to stand almost any kind of weather, and lasting in good condition the greater part of the year. Harrison's Musk makes a capital bed round

trees which are bare at the bottom. The Japanese Maize grows well this year with the abundance of rain, and, in fact, all the plants in this park throughout have a fresh and healthy appearance, though not yet so gay as they will be in a few weeks should fine weather prevail. In Battersea Park, which is the most favoured of any as regards climate, what are termed sub-tropical plants are now growing vigorously. The carpet beds are at their best, and flowering plants, though not used here to the extent they are in Victoria Park, will soon be very gay. Castor-oil plants, Wigandias, tender Aralias, Tobaccos, and similar plants are sturdy and clean, notwithstanding the heavy storms to which they were subjected during early summer. Tree Ferns have made no growth at all, but hard-leaved Cycads, such as Cycas revoluta, the fronds of which are used largely in some parts of America as wreaths in funeral ceremonies, stand the weather well and look fresh and bright. The Fever Gum Tree (Eucalyptus globulus) is represented by young sturdy plants, occupying large beds with an undergrowth of Petunias and similar plants, and the almost hardy African Lily (Agapanthus umbellatus) in the form of dwarf plants has been flowering abundantly in mixed beds, and the New Zealand Flax thrives luxuriantly. The hardy little Fuchsia (F. gracilis) makes capital little hedges, and the Golden-leaved Fuchsia Pillar of Gold is used in a variety of ways with excellent effect. Tuberous Begonias are rather disappointing this year in the open air, the flowers looking all the worse for the heavy rains to which they have been subjected. Abutilon braziliense is the name of a plant remarkable for its large green foliage and bold habit used in mixed beds, whilst plants of Knight's Trumpet Flower (Brugmansia Knighti) will soon make a fine display, the plants being dwarf, branching, and remarkably healthy. The variegated Vine (Vitis heterophylla) makes a capital carpet plant for beds of the India-rubber plant (Ficus elastica), edged with the golden-leaved Japanese Honeysuckle.

In a semi-circular recess on a sloping bank a fine display is made by placing a row of strong sticks similar to those used for Peas, over the tops of which is scrambling Clematis Jackmani, now ablaze with wreaths of purple blossoms, the front of the stakes being hidden by Canary creepers and white Everlasting Peas, in front of which is a band of mixed single Petunias edged with silver-leaved Grass. Near to this is a bed which has been very attractive. It consists of young plants of the silver-leaved Maple (Acer Negundo variegatum), with tall Larkspurs (Delphiniums) planted amongst them, the blue stalwart spikes of the Delphiniums showing with telling effect against the white leaves of the Maples, the ground being carpeted with dwarf Tropæolums. The dwarf early-flowering Chrysanthemums are used as edging plants in places, and in a few weeks they will give a fine display of blossoms. The Chrysanthemums, which, be it remembered, are perfectly hardy and at home in town or country in any ordinary garden soil, are perhaps more useful for garden purposes than the large flowered Chrysanthemums, which often come into flower so late, as to be cut off by frost unless some kind of protection be given them. Of the early-flowering kinds in question there are at present but a few kinds—mostly white, dark crimson, and yellow; but they are excellent for cutting for vases, &c., and they flower from August till November. The old Gazania splendens and its variegated-leaved variety are also used as edging plants on sunny banks, positions in which they yield a mass of golden blossoms all through the summer. The Gazania is easily propagated from cuttings, and may be kept through the winter in a window and be planted out in May or June. Beds of Siebold's Funkia (Funkia Sieboldi), one of the best of hardy plants, are a mass of spikes of lilac blossoms, which being, however, now on the wane, will be replaced by the noble foliage of Aralia papyrifera, plants of which have been judiciously planted among the Funkias.

The Dutchman's Pipe (Aristolochia Sipho) is used with good effect as a pillar plant. A strong stake, 6 ft. or 8 ft. long, is driven into the grass and Aristolochia planted at its foot, forming a pyramid of large, handsome foliage. The flowers of this plant are more curious than attractive, but it is one of the best plants that can be used for quickly covering arbours or rough fences during summer. It is a herbaceous plant, and perfectly hardy in well-drained soils.

The Sumachs (Rhus) are elegant plants seen in bold masses in shrubberies, as they are here. They are kept pruned in the form of low bushes, which is perhaps the best way to grow them. These plants succeed well in the smoke of London as well as any shrub we know of, the Fig not excepted, and if cut down yearly they will throw up vigorous stems clothed with graceful Fern-like foliage.

The beautiful pink-flowered Japanese Anemone (A. japonica) and its white variety have just commenced to flower in borders edging shrubberies, and these plants will give a good display of blossom till severe frosts set in. These Anemones should be grown in all small gardens, for when once planted in light sandy soil they take care of themselves; and they will either grow in the open or under the shade of trees, and flower profusely from August till November, the blooms of the white one, as seen in Battersea Park, resembling those of the Poet's Narcissus, to which they are in every way equal, except that they emit no perfume.

Dahlias planted in beds with an undergrowth of White Paris Daisies will soon be an effective feature, and we noted that among the Dahlias are planted strong clumps of the hardy Flame-flower (Tritoma Uvaria), which long after the Dahlias are cut down by frost will retain their stalwart spikes of brilliant scarlet-orange blossoms, and be effective in conjunction with the Paris Daisies, which, too, withstand an ordinary frost with impunity.

Carpet bedding is carried out here to perfection, as usual, but we notice the designs are much more simple, and therefore more effective, than in former years. One of the most striking round beds is one planted as follows: In the centre is a large star composed of Blue Lobelia, studded with single plants of the variegated Fish-bone Thistle (Chamæpeuce Cassabonæ) and Yucca aloifolia, this star being set in a groundwork of Golden Chickweed (Stellaria aurea), in which are introduced small round patches of the Silver Stonecrop (Sedum acre elegans) with a large Echeveria in the centre of each.

ROSES.

ROSES FOR THE SEASIDE.

There are many whose lot is cast in seaside towns and who yet have the love of a garden implanted in their nature; to such I would write a few words of encouragement, as from experience I am convinced that, if only a real love of flowers be present, success will in the end crown their efforts. Like many others, I lamented the impossibility of growing Roses in such a situation, and, gazing on the smoke-begrimed, wind-blown, moribund standards and climbing Roses that disgrace the gardens in the immediate neighbourhood of the town and sea-shore, I felt convinced that the queen of flowers had deserted part of her legitimate domain. At last, fired by a determination to have some good Roses or die in the attempt, after careful inspection of the various sites I could find in a garden sloping steeply to the sea, and over-shadowed by trees in the sunniest parts, I chose a place, not more than 30 yards from high-water mark, where some shrubs broke the force of the sea-winds, and there made a bank sloping to the south-east. This was properly prepared with fresh soil and rotten manure, and the Roses, dwarfs on the Manetti or Brier, were duly planted, pruned at the end of February, and protected by some Furze branches from the violence of the winter winds. The consequence was that they began to grow very early, and as the late spring was very severe that year, most of my Roses died, and all had a struggle for bare existence. The next year, warned by experience, I pruned very late (in the end of March or first days of April, according to the season), and in May, when the young shoots and foliage were 2 in. or 3 in. long, I placed a band of canvas 18 in. high on the sea side of my beds; this proved a most efficient protection, as all the Roses had been pegged down close to the ground, and in June, when the leaves became firm and the flower-buds swelling, it was removed. The bloom that year was far superior to anything I had dared to expect, and from that time to this, by eliminating those varieties that will not succeed under such conditions, and trying fresh sorts and experiments, the quality of the flowers has improved. The chief points, then, to be insisted on as peculiar to sea-side treatment of Roses are late and severe pruning, sacrificing something of the summer bloom, so as to insure the growth being made as late as possible, protection during May and most of June only, and carefully pegging the Roses down in the case of strong-growing varieties, so as to ensure the sea-breeze blowing over their heads. The next thing is to give a list of the names of those Roses that have succeeded, and also to mention some of the well-known old favourites that have failed, as in spite of all care some refuse to grow or flower, while, happily, others thrive in a manner quite at variance to the descriptions given of them in catalogues most reliable for inland gardens. As a rule, I remark that light-coloured Roses do best near the sea and smoke, as the dark ones often turn purple and discoloured under a sea-breeze or a wind that brings the town smoke over them. In the following list the Rose that succeeds best in its colour is put first, and so on in proportion:—

Hybrid Perpetuals.

Red and crimson.

Marie Baumann
Mdme. Clémence Joigneaux
Madame Victor Verdier
Duke of Edinburgh
Dr. Andry
Horace Vernet

Rose-coloured.

Madame Boll
Marquise de Castellane
Edouard Morren
François Michelon
Paul Néron
Monsieur Noman

Dark-coloured.

Xavier Olibo
Louis Van Houtte

Light-coloured.

Baroness Rothschild
Madame Lacharme
Madame Thérèse Levet
La France
Marquise de Mortémart
Prince of Wales
Boule de Neige
Captain Christy

Among Bourbon Roses the old Souvenir de Malmaison and Sir Joseph Paxton are specially hardy, and Aimée Vibert alone among Noisettes. Of Tea Roses it is needless to say that the invaluable Gloire de Dijon succeeds when well pegged down, its failing being that it is inclined to grow too early in spring. The following also do well when well sheltered :—

Tea Roses.

Adrienne Christophle	Madame Falcot
Boule d'Or	Madame Willermoz
Catherine Mermet	Marie Ducher
Cheshunt Hybrid	Perle de Lyon
Goubault	Regulus
Josephine Malton	Sombreuil

It is curious to notice how many "old friends" fail us by the sea; General Jacqueminot, Jules Margottin, Charles Lefebvre, all the Victor Verdier race, Alfred Colomb, and Sénateur Vaisse refuse to produce even decent blooms with me. If any friend could give a reason why Marie Baumann and Edouard Morren should thrive and Alfred Colomb and Jules Margottin refuse to flourish, I should feel much obliged. Last autumn, finding that all my attempts to make the more tender Noisettes (such as Maréchal Niel, Lamarque, and Triomphe de Rennes) succeed entirely failed, I put up a glass coping, 2 ft. wide, on the top of a wall 5 ft. high, facing east, and glass screens at each end of the coping to prevent the east wind sweeping along the wall. Under this protection I planted in a rich border Maréchal Niel, Lamarque, Souvenir d'un Ami, Perle de Lyon, and other good Roses, and they have grown and flowered with such wonderful luxuriance (when they would not have lived there without this slight protection), that I feel inclined to recommend its trial by all those who, like myself, live in exposed situations. Occasional syringing and watering in dry weather are needed, as the coping keeps off some of the rain from the border close to the wall. If anybody who reads this tale of success and failure be tempted to try and make Roses grow where they had not grown before, my object will have been achieved. H. W.

FRUIT.

STRAWBERRY CULTURE ON LIGHT SOILS.

Those who have soil of a light porous description to deal with will naturally experience more difficulty in obtaining good Strawberries than where the natural staple is more holding and substantial. At the same time it is quite possible to grow fruit of excellent quality in the most unfavourable of soils. All the grower has to do is to counteract the unfavourable conditions as far as may lay in his power. If, for instance, the soil is inclined to parch during the summer months, it should at planting time be trodden or rolled down as hard as it is possible to do. If the surface can be made as hard as a gravel walk, so much the better; there is then less chance of the roots suffering from atmospheric fluctuations, and the plants will not need so much water. This precaution is not needful in the case of soils of a somewhat retentive nature, and it is only where the natural staple is of this description that Strawberry growing for market can be made profitable. In sound loams the particles of soil lie so closely packed together, as to form a solid surface almost impervious to the dessicating influence of the sun—in other words, such soils do not burn. Treading in such cases is by no means necessary, and even mulching, with the exception of a little straw to keep the fruit clean, may be dispensed with. This is the reason why so many who have only had to do with favourable soils fail when they have to deal with land which parches and burns in the hot sun. So great an influence has soil upon the growth of the Strawberry plant, that an entirely different system of culture has often to be pursued in different parts of the same locality, and even of the same garden. As an illustration of this I may mention that in one particular spot in this neighbourhood the Strawberry thrives with rank vigour, plants in a single season attaining extraordinary dimensions, scarcely needing even in the hottest and dryest of seasons any attention with the watering-pot. In another garden hard by the greatest precautions have to be taken to ensure a crop. It will therefore be seen that no general rule can be laid down in this matter; operations must be regulated by the nature of the soil, and if the grower wishes to attain success in the culture of this favourite and wholesome fruit, he must form a correct estimate of the difficulties to be encountered, and make up his mind not to spare any amount of labour which may be necessary to counteract such unfavourable conditions as may naturally exist. Where a little expense is no object there are always means to improve light soils. A few loads of clay spread over the surface until the united action of sun and air, or frost and wind, thoroughly pulverises and crumbles it to pieces, is undoubtedly the very best material for the purpose. For a small garden the outlay for making a piece of ground in this manner would not be very great, and the result would fully justify the expense incurred. Marl, where much is procurable, is also an excellent cultural agent, its beneficial effect being certainly most marked on light lands, its stimulating properties not becoming readily exhausted. In the case of old kitchen gardens where the soil has become deficient in certain nutritive properties, the addition of a little more exercises a most wonderful revivifying effect. By its use alone good crops of fruit may be obtained where repeated applications of manure have failed to induce anything like vigour or fruitfulness. Another good material and one more easily obtained is road-scrapings. These may generally be bought for 6d. per load, the carting costing from one to two shillings extra, according to the distance, or, what is still better, the parings from the sides of the road may be bought at a cheap rate, for, containing, as they do, a large proportion of organic matter, they not only impart solidity, but add considerably to the fertility of the soil. Light soils do not need so much previous preparation as those of a retentive nature if well stirred once or twice with the fork during September, and there will remain nothing more to do than to add such manure as may be considered necessary, breaking it well to pieces and forking it in as deeply as possible. Any of the materials above recommended which are to be employed should at the same time be forked in with the top spit. There are various methods of forming a Strawberry plantation. In good strong holding soils it is customary to allow quite 2½ ft. between the rows, and 18 in. from plant to plant, and even in light soils, if the ground is heavily manured, deeply stirred, and well mulched in the summer, this distance cannot be accounted too much. We will now suppose that a good tilth has been prepared in the manner recommended. We have only then to choose a dry day, and roll or tread the surface quite hard. The more sandy, light, and porous the natural staple, the greater necessity is there for making it firm. Having completed this operation, strike out the rows at the required distance by patting the line, so that its form is impressed upon the soil. Mark the place for each plant and set it in firmly with the trowel, settling it well in place by treading firmly, but gently, round the collar. When thus fixed there is but little danger of hard frost drawing them out of the ground. If planting has been carefully conducted, and the roots preserved against the drying influence of the air, fresh fibres will be immediately formed, and each plant will have thrust feelers far into the soil before winter arrives. The following March run the hoe over the ground and then mulch with good stable manure, or, failing this, litter of some kind or short Grass. To ensure the best results, every truss of bloom should be picked off the first year. The produce in any case cannot be much, and the little self-denial exercised will be rewarded by a bountiful crop the next year. During the summer every attention must be given to cleanliness, pulling up weeds as they appear, at the same time cutting off all runners as they are made, and watering freely in hot weather. A complaint that one frequently hears is, that on light soils the plantations soon wear out, the crop after the first year frequently being very deficient in quality and quantity. This, however, is too often the fault of the grower, who is apt to forget that a Strawberry plant has its requirements even after it has ripened off its crop of fruit. It frequently happens that very hot weather sets in after the crop is gathered, in which case, unless the stools are at once watered, they are apt to suffer to a serious extent, or do not start into growth in time to perfect their crowns. Some growers recommend cutting off the old leaves; others condemn this practice as barbarous. My experience tends to a middle course. If some of the old rusty leaves are cut off and a good watering given, the energies of the plant are then concentrated upon the production of fresh foliage, and growth generally is more free than when the entire mass of old leaves is allowed to remain.

Large-leaved Gunnera in the open air.

There is another point to which I would direct the attention of those engaged in Strawberry culture. When a plant has fruited the second year, it will, if at all vigorous, be found to consist of a number of crowns, large and small, and, in the case of many varieties, very much crowded together. These crowns the third year will many of them prove sterile, twenty of them perhaps not giving half-a-dozen trusses of bloom. This is owing to the foliage being so dense and the crowns so thick together, that sun and air cannot well penetrate to them; they do not mature, hence the necessity for partial defoliation and thinning out the crowns. Where a dozen crowns exist quite a third should be cut clean away. If at the same time a top-dressing of good free soil be given and worked up well around the collar, the production of new roots from the base of the crown will be stimulated and the plant will take on as it were a renewal of life and energy. This thinning out of the crowns is but little understood and but seldom practised, hence the reason that plantations so often wear out and become unfruitful in a short time. I have known plantations last five or six years when thus yearly attended to. At any rate, it is a practice that I can conscientiously recommend, and the little labour involved thereby should not be grudged, being much less than would be incurred by making fresh beds. There is one particular method of making a Strawberry plantation which I would recommend to those who may have soils of a peculiarly unfavourably nature to deal with. I allude to the formation of beds some 4 ft. in width, the plants

to be set, if plenty of runners are obtainable, some 9 in. apart, to be thinned the following season, leaving every alternate plant. The whole surface of the soil being covered with foliage, the sun cannot well act upon and parch it; the plants, therefore, do not die off. In this manner of growing heavy mulchings are not necessary, an annual top-dressing of soil and a sprinkling of guano in early spring being all that is needed. Thinning and defoliation being duly attended to, such beds will last for years. The crop will be somewhat later than that produced by isolated stools, but there is the advantage of the bloom not being cut by frost, which it seldom is, owing to its being so much protected by the foliage. The beds, being only 4 ft. wide, with a path on each side, allow of the fruit being gathered with ease; and by bending some Hazel rods over and tying them together in the middle, the whole of the fruit may be secured against the attacks of birds. J. Cornhill.

Byfleet, Surrey.

PRUNING AND GRAFTING.

Roughly speaking, the objects of all pruning are to obtain fruit, but the subject is a wide one, and branches off into several collateral issues. For instance, we sometimes prune to secure bulk of tree by heading back the main branches, but the ultimate object still is to obtain fruit, as a tree must be built up before it can bear. Then, again, trees are pruned to assume various forms, by cutting to a bud pointing in any given direction. In pruning orchard trees, the main object should be to let in the sunshine; it increases the circulation, and sends the forces of the tree into the right channel for fruit-bearing; and to that end the dense places should be thinned, at the same time cutting out all crossing, deformed, and badly-placed branches. Different kinds of fruits require different modes of pruning; some bear best on spurs, and others on the previous year's wood. One of the chief aims of pruning is the concentration of the tree's efforts by decreasing the number of anything; increased development is secured for those left. If all regularly pruned trees were thinned in summer, so that the sun could look into the obscure places, there would be more and better fruit; and if growers of fruit give thought to the matter they will soon learn the value of having a tree clothed, but not crowded, with good, strong, healthy foliage, where each leaf and bud has had a reasonable share of sun and air; and this result cannot be obtained permanently by either the non-pruner or by those who prune immoderately.

Wigandia, a plant for warm sheltered gardens in southern counties only.

Without reckoning budding, there are two methods of grafting that are commonly practised in gardens, viz., whip-grafting and crown or rind grafting. In the former case, which is applicable mostly to young stocks, the scion is fitted on the stock in the same manner as a whip is fitted on to its handle. The stock is headed down and a good slice cut off one side. The scion—a piece of well-ripened wood, from 4 in. to 6 in. long—is prepared in a similar manner by having a slice about 2 in. long cut from one side and made to fit close to the stock, at least on one side, so that the bark on each may meet and unite. A better and closer union is to be obtained by making a downward cut in the stock, forming a small slit; a similar cut is made in the scion, so as to form a tongue to fit into the slit of the stock, and the whole is bound firmly together with soft matting. Any one learning to graft may practice upon the branches of any growing trees until they have gained experience in the handling of the knife. Crown or rind-grafting is more especially suited for headed-down trees or large stocks. The stock is first headed down, and the cut smoothed with a knife. Three or four scions may be placed on each branch; they should be prepared by cutting one side flat and tapering, the cut portion to be about 2 in. long; the outer bark on the uncut face of the scion, opposite to the part cut flat, should be shaved off carefully, leaving on as much as possible of the cambium or under bark. The point of the knife is then drawn up the bark of the stock, about as deep as the scions will reach. A skewer of bone or ivory, of similar shape to the scion, is then inserted between the rind and the wood opposite the niches cut in the bark, and as soon as the instrument is withdrawn, the prepared scions are inserted, and tied in and clayed immediately.

Budding is an equally simple process, with this difference—the grafter inserts a portion of wood and several buds, whilst the budder only takes one bud, generally without any wood, and inserts it by making a slit in the back of the stock. The bud should be a well developed one, and should be cut from the shoot with a small shield of bark protecting above and below, and the bud and bark is slipped underneath the bark of the stock and tied in carefully, but firmly. Grafting is best done in spring, when the sap rises, the grafts having been cut a month previously and laid in damp earth, as it is necessary the stock should be in advance of the scion. On the other hand, in budding, the bud is taken from one growing shoot, and inserted in another immediately in summer. E. H.

Strawberries.—All should ere this be in their fruiting pots, and be growing rapidly. Keep the runners constantly pinched off and never allow them to suffer even slightly in the matter of watering, or to become drawn and weakly from standing too closely together. They should be kept free from weeds by pulling them out as soon as perceived, as under no circumstances should the surface soil be broken up; such a proceeding should ever be looked upon as wanton destruction of the best roots of the plants. If a small proportion of bone manure was incorporated with the soil for potting, no manure water will be required, as the aim should be the obtaining of sturdy, fruitful crowns rather than an immense profusion of leaves, accompanied as they would be with large sappy crowns difficult to ripen.

How to Catch Earwigs. — Taking advantage of the fact that these insects feed in the night, almost any substance in which they can conceal themselves in the day may be employed to trap them. The usual practice of placing a small inverted flower-pot with a bit of Moss in the bottom on the top of the stake to which the plant is tied is not a bad means of catching them, provided the pots be regularly examined. Another trap commonly used is small bundles of Bean-stalks tied up, cut 6 in. or 8 in. long, placed in each plant, and looked over daily by shaking the end of the bundle on a board or other substance, by which they can be destroyed. The most simple and effective traps are pieces of newspaper, crumpled roughly up in the hand, and stuck anywhere in the plants, unfolding them two or three times a week, when numbers of the insects will be found concealed in them. If there happens to have been bred a nest of young robins near the ground, the numbers of earwigs they will eat, when they have taken flight and got old enough to find their own food, will astonish anyone taking the trouble to watch their movements. In the case of Dahlias (and there is, perhaps, no flower to which they do so much harm as to the Dahlia), the use of thin muslin bags, in which the buds are placed before they expand, drawn up close round the stalk of the flower so as to prevent the insects getting to them, is also a method followed by some growers. A piece of cotton-wool, twisted round the flower-stem just behind the bud, will prevent them getting to the flowers. By resorting to some or all of these methods, their numbers can be so far kept under as to prevent the disappointment of finding all the best buds rendered useless. As preventives, the circular earthen pans that are made for the purpose, in the fashion of a collar to the plant, are very effective. They should be put down firmly and kept full of water, and nothing in the shape of a bridge should ever be allowed to make a way for the earwigs to cross the water. Mulching is said by some to induce earwigs, but this hardly seems reasonable, for whatever keeps the ground cool and moist acts as a preventive.

House and Window Gardening.

GARDENING ON WINDOW-SILLS.

In outside window gardening there is abundant room for more variety than at present; many plants not commonly met with in such positions might be advantageously used. Bright and continuous effects may be produced by annuals alone if sown at different times and brought forward in boxes successionally. Ivy and other creepers might be planted along the front of the boxes and allowed to hang down naturally over the side, or they may be planted at the ends and trained upwards. Virginian Creepers, again, are exceedingly useful for this purpose. The Canary Creeper and other Tropæolums would be quite at home in boxes outside the windows, provided the soil was rich and water was liberally supplied. There are, in fact, so many things that may be successfully grown outside windows in boxes that one wonders that so little variety is seen.

In order to keep a window gay and interesting I should suggest that several sets of boxes about 5 in. deep be prepared, using the deepest for the summer-blooming plants. The year might be commenced with a box filled with Sedums, not necessarily all of one kind. There might be a mixture with the long shoots falling over the box gracefully on all sides; with the Sedums might be associated in early spring Crocuses and Snowdrops planted in October. Hyacinths and Tulips might also be intermingled, and there would be no occasion to replant the boxes every year. What a sensation would be created by a box brimfull of common Yellow Primrose early in spring, or the Wild Hyacinth or Bluebell! Many a dweller in large towns who was country-born would be enraptured by the sight of the flowers of their childhood. Polyanthuses and Alpine Auriculas from seed would also be very effective, and could be obtained at a very small cost and trouble; in succession might follow autumn-sown annuals of many bright and beautiful kinds. In summer Pelargoniums, Stocks, Mig

nonette, &c., would look gay and give oft a delightful perfume ; and when the autumn and winter came round there would be dwarf Chrysanthemums, single Russian Violets, and dwarf Shrubs, including berry-bearing species. If some pains be taken with the Violets to get plants started early, they will begin flowering in autumn, and continue to bloom through the winter.

There are numbers of plants that would be as effective as those I have named, or even more so, but I hope I have already said enough to show that the materials for beautifying the humblest home are neither scanty nor costly, and that the care and attention necessary to their successful development will open up new sources of thought and supply a pure source of enjoyment, all the more gratifying because untainted by selfishness. If the outside of the window may be described as the poor man's flower garden, the inside may, by a similar figure of speech, be called his hothouse ; or he may have his aquarium, furnished with gold fish, and, to keep the water pure, a few aquatic plants.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

August 16.—Sowing Radishes, Snowball and Stone Turnips, Incomparable, Enfield Market, Imperial, Matchless, and Little Pixie Cabbages, Mignonette in pots, Bath Cos, Hicks' Cos, Stansted Park, and All the Year Round Lettuces, Frogmore Walcheren, and Early London Cauliflower ; putting in cuttings of Salvia, Gazania, Balm, Pelargonium, Hydrangea, Fuchsia, and a few Achyranthes for stock ; planting Sweet Williams and Rockets ; layering Carnations.

Aug. 17.—Sowing Cucumbers to grow in pots, also Prickly Spinach ; potting Madame Vaucher Pelargonium for autumn, also double Wallflowers ; cuttings of Ageratum, Heliotrope, Agathæa, and Verbenas put in a cold frame plunged in ashes; planting Wallflowers, Endive on Potato land, and July-sown Cabbage ; putting nets up to Vineries to keep out wasps ; taking up seed Potatoes (Prolifics) ; cutting Lavender ; pulling up autumn-sown Onions ; digging some land for spring annuals ; making pit for Endive and for Bath Cos Lettuce and latest Cucumbers ; earthing up Cauliflower.

Aug. 18.—Sowing Globe, Tripoli, and Strasburg Onions, Schizanthus, East Lothian, and Brompton Stocks ; potting Vesuvius and Dr. Lindley Pelargoniums for winter ; putting Primulas into their flowering pots ; also putting in cuttings of bedding Pelargoniums ; netting Plums ; putting Pinks in a sunny place under a wall ; putting Shallots and Garlic under cover ; budding Roses ; levelling ground for autumn Onions ; hoeing up Strawberries and manuring for early Cabbage ; cutting Laurels over a second time ; clipping Yew hedges.

Aug. 19.—Sowing hardy annuals ; potting off some late-sown Cinerarias, also Pinks ; putting in cuttings of Hollyhock and Senecio ; planting Antirrhinums ; pricking out Stocks and Sweet Williams ; repotting the largest Cinerarias for early bloom, some Musk seedlings and Bouvardias ; lifting Ashtop and Handsworth Potatoes for seed ; earthing up Celery ; making a bed for Violets ; painting Apple trees with paraffin for American blight ; thinning late-sown Carrots and Turnips ; also last-sown Mignonette, and taking old flowers off in order to encourage them to grow again.

Aug. 20.—Sowing Chærophyllum bulbosum, Radish, and also Spanish Radish, Silene pendula, and S. p. alba, Nemophila insignis, and Pansy ; likewise last Mignonette; potting Masdevallias and Odontoglossums ; put in cuttings of Nasturtium, Gazania, Petunia; planting July-sown Bath Cos Lettuce ; layering Strawberry runners for planting ; also Chrysanthemums and Anne Boleyn Pinks ; tying up Stephanotis, Allamandas, and Roses ; shifting intermediate Stocks into 6-in. and 8-in. pots ; making land ready for Bath Cos Lettuce, July-sown Cabbage, and Endive ; also for Leeks and Wallflowers ; mowing off one bed of Parsley to get it to grow for winter.

Aug. 21.—Sowing Beck's Gem Pea ; potting scented-leaved Pelargoniums ; putting in cuttings of Veronicas, show Pelargoniums, and a few more Manglesi ; staking all dwarf Mignonette that is ready ; moving Primulas from behind wall to pits ; earthing-up late winter Greens ; thinning out last-sown Turnips and latest-sown Mignonette ; stopping straggling shoots on early Vines ; exposing Peaches out-of-doors ; taking runners off potted Strawberry plants ; taking off breastwood from wall trees.

Plants and Flowers in pots ready for house-decoration :—

Justicias
Mignonette
Bouvardias
Scarlet Geranium
French Geranium
Double Geranium
Scutellaria Mocciniana
Godetia in variety
Balsams
Agrostis pulchella
Heliotrope
Zinnia elegans
Carnations
Clove Carnation
Roses
Gardenias
Pansies
Spiræas
Stephanotis
Moss Roses
Stocks
Calceolaria
Fuchsia
Hydrangea
Lobelia
Pelargoniums
Cockscombs
Petunia
Myrtle
Musk
Blue Cornflower
Sweet Pea
Lilium auratum
,, lancifolium
Dianthus Heddewigi
Calliopsis
Lilies

Glasshouses.

The deficiency of blooming plants in conservatories at the present time of the year may be compensated by a liberal admixture of such plants as Draccenas and Coleus. Of the former take such kinds as Cooperi, ferrea, and terminalis ; the bright markings of their leaves will supply the place of flowers, and the plants will not receive injury for the next two months by being placed in a house without fire-heat. The different varieties of Coleus should be placed so as to get as much light as possible, otherwise they become drawn and have an unsightly appearance. The old Plumbago capensis is another useful plant for this time of the year, not grown nearly so much as it deserves to be. The present is a good time to propagate it. The small half-ripe side shoots will strike freely inserted in small pots under bell-glasses in a warm house or frame. These, when struck, should be encouraged to make growth before the autumn gets too far advanced. They should be wintered in a temperature of 45° or 50°. In the spring they should be headed down and potted in 6-in. or 8-in. pots, using good fibrous loam. If desired some may be grown on in larger pots, but for general decoration they are more useful in a comparatively small state. The plants will last for years by cutting them back in the spring just before they commence growth and when they have broken, replacing a portion of the old soil with new material, returning them to the same or a size larger pot. Fuchsias should have their seed-pods picked off regularly, or they soon cease to flower freely ; they ought to be supplied twice a week with weak manure water. Double Petunias are very useful at this season, either as decorative plants or for furnishing cut flowers. They should receive regular attention in the way of stopping and tying, to induce them to break back, or, from their quick, somewhat straggling habit of growth, they become unsightly. Lilium auratum is a most useful subject for conservatory decoration at this season, but should not be introduced in too great numbers at a time, as its perfume, being so powerful, is oppressive. Attend well to the different varieties of Lilium lancifolium, by keeping them neatly tied out, and supplying them regularly two or three times a week with manure water, otherwise the soil becomes exhausted and they lose their bottom leaves, which destroys half the beauty of the plants. They must on no account be allowed at this season to suffer from want of water.

Solanum macrophyllum, as grown in the London Parks.

Pillar Plants.—Many of the plants classed as greenhouse climbers, and employed for covering the usual roof supports, are far from being fit for the purpose. They are often such strong growers that they quickly run up to the top, leaving the lower portion of the pillars, where their presence is much wanted, devoid of leaves. Where plants for use in this way are required they are usually wanted to give immediate effect, and for that purpose it is well to prepare them beforehand by growing them on in pots until they are large enough to produce some effect at once ; if healthy young plants are got now and an extra shift given them, time will be gained. It is scarcely necessary to say that instead of having the shoots pinched so as to form bushy specimens, they should be trained erect, only stopping a few of the strongest growths at different heights to cause these to break out. Subjoined are a few of the best plants for the purpose : Cantua dependens bears deep pink flowers, produced like those of Fuchsia corymbiflora ; this is only fit for a pillar, as its determinately erect habit makes it unsuitable for growing in the ordinary way. Hovea Celsi, the lovely blue flowers of which are unsurpassed by those of any Pea-blossomed plant, has a habit which just fits it for growing on pillars. Habrothamnus elegans, which is stronger in growth than the two preceding, can also be easily kept within bounds, and is likewise an excellent subject for the purpose indicated. Mitraria coccinea (the Scarlet Mitre-flower) is another effective plant in a position of this kind, as by annual judicious cutting-back it can be had in flower from the bottom up to any reasonable height. The old Hoya carnosa, which will succeed for many years in a very small pot, is nowhere seen to greater advantage than when trained to a pillar. The blue Plumbago capensis, too, needs comparatively little root-space, and grows up quickly ; its foliage is always neat, and it will keep on for many weeks producing its handsome pale blue flowers. Clianthus magnificus and C. puniceus are both good pillar plants, which are not disposed to get too large. Fuchsia corymbiflora is never seen in better condition than when grown in this way. The red and white Lapagerias are amongst the best plants that can be employed for the purpose ; the only objection to their use being that as they get old they require considerably more root room than is afforded by the usually small space that is available at the foot of a greenhouse or conservatory pillar wherein to turn a plant out, and if kept in pots or boxes the arrangement of the house is generally such as to produce an unsightly appearance. Plants of any or all of these, well prepared beforehand, will, when transferred to the positions they are to occupy, soon obviate the disagreeable effects of bare pillars.

Achimenes.—These should have every attention as they go out of bloom to assist them in forming and ripening their tubers ; the best place in which to treat them at this season for that purpose is a pit or frame where they can be kept moderately close and shaded, in additon to which they should be freely syringed overhead, that the leaves may be maintained in a fresh, healthy condition. Achimenes are too frequently stowed away directly they cease flowering or become the least shabby, and water entirely withheld from them, a course of treatment the reverse of what they require, as it is just at that time assistance is needed in rendering the drying-off process gradual and natural. By affording the first batch a little extra attention, they will form an abundance of fine, large tubers, superior in every way to any that can

be obtained from those now coming on, which may therefore be discarded as soon as they have discontinued blooming.

Eucharis amazonica.—Valuable as this is at any season, it is never more welcome than during the autumn and winter months, a time of the year when such choice blooms are doubly appreciated. Fortunately, they may be had at that season almost as readily as at any other, provided there be the necessary convenience for growing them and a good stock of plants to work with. Where this is the case, a portion of the plants should be always resting and others coming on in different stages, so as to keep up a constant succession of flowers for cutting or other purposes. Those intended for blooming during October, November, and December should now be at rest in a cool house or pit, where they have only had sufficient water afforded them to keep the leaves alive and fresh. If a portion of these be transferred into hot-house heat and kept well supplied with tepid water, they will soon commence to throw up their flower-spikes, and when these are cut the plants should be grown on for a time before they are again put to rest. Owing to the rapid way in which the bulbs increase in number, frequent division and repotting are necessary in order to renew the soil and make a separation of the large flowering roots from those of smaller size, which can either be discarded or kept for stock. The soil that suits them best is rough lumps of peat, leaf-soil, and a sprinkling of rotten manure, to which should be added sufficient sand to keep the whole porous and open, so that the water may pass freely through. To aid this the pots must be thoroughly well drained by placing at least 2 in. of crocks in them, over which some half-rotten leaves should be scattered, to prevent the finer soil from running amongst them and filling the interstices. Water somewhat sparingly for the first week or two till they get fresh hold of the soil, and then gradually increase the supply as the pots fill with roots, after which, if the heat be sufficient, they can scarcely have too much, either at the roots or overhead, where a good syringing is always acceptable.

Flower Garden.

In a flowering state, Roses of every description are all the better for having all bad flowers regularly removed, not more for the sake of neatness than for the encouragement of successional blooms. If excessive growth is exhibited by plants on rockwork, there is danger of the stronger overpowering the weaker unless early attention be paid to them. The present is a very good time to propagate many of this class of plants by division. The propagating of bedding plants may now be commenced, cutting off straggling shoots for the purpose. A fortnight hence will be ample time to put in a few store pots of cuttings of such plants as do not lift well; amongst these are Petunias, Verbenas, Heliotropes, Lobelias, Coleus, Alternantheras, and Iresines. Still, no pains ought to be spared to render the flower garden as attractive as circumstances will permit by the preservation to the fullest extent of neatness, both as regards the beds, turf, and walks.

Indoor Fruit.

Vines.—Remove the lights if practicable from the earliest Vineries in which all the wood is thoroughly well ripened and the fruit cut, and paint and repair the house. Where Grapes are now ripe and hanging, precautions should be taken against the ravages of wasps and other depredators, either by placing the clusters in little muslin bags, or, if convenient, covering over all openings for ventilation with sheets of tiffany, hexagon netting, or frigi domo. A somewhat dry atmosphere is necessary where Grapes are ripe and colouring, but still guard against too much dryness. In late Vineries where the berries are swelling give air night and day, and maintain an equal temperature by means of a little fire-heat, which dispels stagnant damp in dull weather and renders the atmosphere sweet and healthy; give also abundance of water, and sometimes manure water to the borders, and liberally damp all paths, walls, and floors during the day, otherwise shrivelling soon sets in, and red spider makes its appearance.

Peaches and Nectarines.—In order to give late fruits every chance of ripening properly, fully expose them to the influence of the sun. Trim out all shoots not required for next year's work, so as to thoroughly ripen those retained. Where the fruit has been gathered, and the wood is well matured, ventilate the houses as much as possible night and day, and syringe with a solution of sulphur for the eradication of red spider, and use some dissolved soft-soap or Gishurst Compound in the water when syringing for the destruction of scale. Keep the borders moderately moist, for drought under any circumstances is exceedingly harmful to the trees.

Melons.—Prevent over-luxuriance by means of kindly treatment and a little ventilation at night as well as during the day, in preference to stinting the supply of moisture and pinching severely. However, their growth must be regulated and held in check, and attention must be paid to the fertilisation of the blooms. To those whose fruits are swelling, give heavy applications of water, and occasionally some liquid manure.

Cucumbers.—The plants for winter fruiting should now be sown, and cuttings struck from present fruiters to succeed them. Worn-out plants may now be cut in rather severely, and the borders mulched and well watered, and the linings renewed; the plants soon make a fresh start and bear well for some time yet. Attend to the usual routine of thinning the leaves, shoots, and fruits whilst in a young state.

Outdoor Fruit.

It is now time that all summer pruning and stopping of shoots should be finished, as there is now no danger of the trees making growth to be in any way detrimental to the formation and full development of fruit-buds for next season. Any such work still to be done should be completed as soon as possible, after which the shoots should be neatly laid or tied in, and the ripening fruit be exposed to the influence of sun and air by having the foliage drawn on one side, or, if need be, removed altogether; but this should only be done when the leaves cover the fruit, and so hinder its colouring properly. Should the summer continue hot and dry, watering will be a serious item of garden labour, as it is from this date to the end of September that fruit trees require most water. If that should be scarce mulch deeply with litter or Grass. Gather Apricots, Peaches, and Nectarines a day or two before they are intended to be used and before the sun touches them in the morning; they will then keep for several days in a cool room and be all the better for it. Of course, they should be laid on some soft substance, such as dry Moss or wadding. Early kinds of Pears, such as Citron des Carmes, Belle de Bruxelles, and Jargonelle, are now sufficiently ripe to gather; it is not well to allow them to fully ripen on the trees, as then the flavour is not nearly so good, and the fruit soon decays. Let all runners required for forcing and new plantations of Strawberries be taken off as early as possible, in order that the beds may be cleared of runners and bad foliage, after which slightly point over between the rows, and give a fresh mulching of rotten manure. Water freely all newly-planted beds, to get growth completed by the end of September. A nursery bed of runners should be kept on hand to make good any failure that may occur.

Vegetables.

August is a month of sowing and transplanting. If the weather be dry then the seeds require moisture; and in order to best ensure it, let the ground be deeply dug, levelled, and rolled, and sown with as much expedition as possible, so as to prevent it from parting with its moisture; a mat or some litter placed over it until the seeds begin to germinate will also be found useful in periods of drought. The hoe should be in constant use, and all weeds and vegetable refuse should be collected in a heap, where, by mixing it with lime and by means of frequent turnings, insect life, and also that of the seeds of weeds, may be destroyed and decomposition accelerated. Hoeing and surface-stirring should be rigorously persevered in, and slugs and insects should be kept in check by means of dressings of soot and lime. Never permit vegetables to run to seed, unless required for that purpose, and then they should have a place set apart for them. Manure well and trench every spare piece of ground, which if uncropped should be ridged. In dry weather abundantly water all kinds of crops that will be removed before winter, but to such as remain during that season water should be judiciously applied, as too much induces soft growth liable to be destroyed by frost.

Endive and Lettuce.—Ground should now be prepared for the principal crop of Endive and autumn Lettuce; for these it ought to be well manured and in a moderately dry position. Do not overcrowd the plants, especially Endive. The rows of Endive should be 15 in. or 18 in. apart, according to the condition of the soil, giving the most room where the growth is likely to be strongest. Lettuce, especially where the small Cabbage variety (such as Tom Thumb) is planted, need not have so much room. More Endive should now be sown. For general use the Green Curled is most esteemed, but where the Broad-leaved Batavian is liked a pinch of each may be put in. Do not sow the seeds too thickly; they are liable to the attacks of birds or insects, and usually almost every seed vegetates. Previous sowings that are already up, if too thick, should be thinned out sufficiently to allow them room, or they get drawn up so weakly as to be long in getting hold when planted out. Some Lettuce—Tom Thumb, Black-seeded Bath Cos, and likewise the hardy Hammersmith—should also be now sown; the last-named sort is not equal in quality to the Cos varieties, but in many places it will stand the winter where other kinds would fail.

Ridge Cucumbers and Vegetable Marrows must be plentifully supplied with water, or they cannot possibly keep on bearing. It should be given in quantity sufficient to reach as far as the roots extend.

Onions.—As soon as these show signs of completing growth they should at once be pulled up, or they will commence to make fresh roots, which injures their keeping properties. They are all the better for being dried quickly. Where a moderate quantity only is grown that can be dealt with in this way; the old method of spreading them thinly on a slate or tile roof has the advantage that if much wet weather should follow immediately upon their being drawn they are not so liable to root afresh as if laid on the bed to dry; or the simple plan may be followed of tying them in bunches of eight or ten immediately they are pulled, and hanging them up on the outside walls of a building that has an overhanging eave sufficient to throw off the rains; the north side is the best for keeping them late in the spring, as there they have not the disposition to grow so early. Shallots, if not already taken up, should be at once removed to a dry place and kept there.

How to Grow Rhubarb.—Rhubarb will grow on many kinds of soil, but the richer and deeper it is the finer will be its quality and the larger its size. The situation should also be moderately dry, or made so by drainage. It will grow in clay, peat, or the bog-earth of the fens. We have seen it succeed remarkably well in mud cleaned out from the river. Perhaps, had it a choice, it would elect, like most other garden plants, a turfy loam, leaning to clay rather than sand. When the leaves get fairly into growth it needs some strong stimulant to keep them growing. The larger the leaves of one season the stronger will be the crown for the next; hence the importance of rich feeding all through the growing season. It is a good plan in small gardens to plant Rhubarb near the depôt for house sewage, so that it may be nourished with strong waters as well as rich solid manure; 4 ft. at least of a rich root-run should be provided for it. For new plantations the ground should be thoroughly trenched and the manure carefully incorporated with it. Its productive force should be kept up afterwards by an annual dressing from 4 in. to 6 in. in thickness. No plant is more easily increased and multiplied than Rhubarb; plants of two or more years old seed freely if permitted to do so. Unless seed be required, however, they should not be allowed to do so, as seed-bearing weakens the crowns. The seeds ripen about the end of September, and may be sown at once in shallow

drills 1 yard apart, or they may be sown in February. As soon as they are well up, thin the plants to 18 in. or 2 ft. asunder, according to the size of the plant and the intention of the cultivator. If intended to remain where they are, 1 yard apart is close enough—indeed, too close for the Victoria variety. Some, however, prefer rows 2 ft. apart, and thinning the plants to 1 ft. only the first season; then in the October or February following fresh ground is prepared, and the Victoria transplanted at distances of from 4 ft. to 6 ft. by 4 ft., and the Defiance 3 ft. by 18 in. or 2 ft. The best plan is to sow Rhubarb where it is to remain, as it forms immense roots that are easily broken, and to break it is to injure it more or less. Nevertheless, a very common mode of propagating Rhubarb is by root division. The huge stool or fleshy root is sliced into as many portions as there are crowns to it with a sharp knife or spade, and each slice forms a new plant. This is rather a barbarous mode of increase. Gathering Rhubarb and when to cease gathering are matters which require more attention than they generally receive. In gathering, the proper method is to give the leaf-stalk a twist outward and a sudden jerk down at the same moment. From want of attention to this, many tear off the crown with the base of the leaf-stalk. Again, too many leaves should not be gathered at once. If a plant have only a dozen leaves, do not gather more than six of them, and let these be the lowest. As to the age of the stalk, that depends a good deal upon taste. Some prefer Rhubarb when the leaves are freshly unrolled, others when they are half-grown, and others when they are fully grown. Of course there is great waste if the stalks be gathered before they have reached their full length. Rhubarb is at its best just when the leaf has reached full size. It can hardly be too old for preserving, and is seldom gathered till the end of August for that purpose. As to the time of ceasing to gather Rhubarb, it should certainly be not later than August if the gathering is to be annual: this leaves but little time for the last leaves to ripen good crowns for the next year's crop. All the leaves removed have doubtless been a loss to the plant: they did much to weaken and nothing to strengthen it; it is only the leaves left on that recoup it for its loss in those taken off. Hence the importance of rich food to replenish the plant and time for the maturation of the later growth; and it need hardly be said that no weed must be permitted to grow at the expense of the Rhubarb plants. Grown as here briefly set forth, perhaps no crop yields a heavier or more profitable return.—S.

Potato Disease.—I am sorry to say the Potato disease is showing itself very plainly among early Potatoes in my neighbourhood. I have pulled up all the haulm and hope thereby to save them. I was very fortunate last year in doing so, having enough to last me till March. Many of my neighbours are taking a leaf out of my book this year.—R. H.

Large Cauliflowers.—I saw cut, on the 19th of July, in the nurseries of Mr. C. J. Baker, Littlehampton, Sussex, four Cauliflowers, called the new Italian Ne Plus Ultra, one of which weighed 12 lb., the total weight of the four being 40 lb. They gained a first-class certificate at the West Sussex Monthly Exhibition.—A Visitor at Littlehampton.

Tomatoes in Pots under Glass.—Tomatoes in the open air are often late in ripening, but fortunately we are able to gather plenty from pots standing on the front shelf in one of the houses, and trained up near the glass. Wherever there is shelf room in a warm house Tomatoes may be had in abundance without much trouble.

Late Peas in Pots.—Where very late Peas are required, some of the dwarf early kinds, such as Blue Peter, Gem, and Unique, might be sown now, not too thickly, in 8-in. pots. There is an advantage in growing the last crop in pots, because in the early period of their development they can be grown on the north side of a fence surrounded by a cool, genial atmosphere, and when the sun loses power and the heat is moderate, they can be moved to a warmer position, or be placed, if necessary, under glass, to set their blossoms and fill out their pods.

Late French Beans.—Plant any of the small early kinds in a frame or pit. Fork up the soil, and pick out the roots, and give a good watering if the soil be dry a few hours before planting the Beans; the lights may remain off till the approach of cold weather. A few may also yet be planted on a warm south border if a frame and lights can be placed over them before frost comes. In the event of a mild autumn they will come in useful.

Cauliflowers.—From the 18th of this month to the 1st of September, according to situation and other circumstances, will be a suitable time to sow the main crop of Cauliflowers, but if they are to be wintered under glass, the last week in this month will be in most places quite early enough. I always sow with the early kinds a few seeds of Autumn Giant: it is so valuable for cutting now and onwards, and it produces a close firm heart in the hottest weather, when frequently the Walcheren is useless.

Sawdust in Gardens.—With reference to my remarks on the foregoing, on page 209, July 3, when answering "Crosscut's" question on page 180, June 12, I had no thought of calling in question "Solicitor's Clerk's" or any one else's answer or experience. If your subscribers will refer to my remarks on page 209, July 3, they will observe "I will *just* (or *only* if preferred) state my own experience." I demur to any correspondent putting words into other's mouths they did not use. I do not think the columns of valuable periodicals, such as Gardening Illustrated, should be made the medium of personal attacks, as such a course would inevitably tend to reduce its value as a medium for collecting and disseminating experience. I did not say I obtained "several," but a "few" sacks (to be exact, however, three). Again, I cannot see how "Solicitor's Clerk" can possibly construe my remarks as "giving the sawdust the full credit of enriching the soil," when I stated most distinctly "I do not know that there would be any manurial properties in sawdust but used as I have described," viz., in conjunction with manure, ashes, soot, salt, and lime, &c.; also a few lines further down: "I can recommend sawdust if used in combination with the other ingredients." I think any one will readily admit that my inference was that I did *not* recommend sawdust alone, but "in conjunction with other ingredients." This latter I still maintain. If "Crosscut" has a garden of clay, if he does as I say on page 209, July 3, I have no doubt whatever that the result will be to him satisfactory. Having saved and had bound the first volume, I have referred to my question on page 397, and I find I asked "whether sawdust would be a good thing to further assist (in conjunction with ashes, manure, and refuse) in lightening the soil." On page 428 "Solicitor's Clerk" and "E. H.," as I understood, kindly gave me their experience; but as I had not the time or opportunity for "charring the sawdust," or "letting it lie in a heap for twelve months," I, after due consideration, decided to do as I described in my remarks of July 3, with the result also therein described. I take it that the object we all have in view is benefiting one another by relating our experience in all the various branches of gardening, and not to pull one another to pieces and carp at words as if we were in a law court, and try and make it appear that some correspondent used words that he did not, as if so I shall once for all decline to answer any more questions by giving my experience; but if our object is mutual benefit—if at any time I state anything that can be improved upon I shall most readily accept any correction, and thankfully, too. "Crosscut's" question being "Is sawdust of any use in a garden? Would it improve a clayey soil?" I reaffirm that, used in conjunction with the material and in the manner described by myself, sawdust is of use, and would improve a clayey soil. If, however, it could be obtained from some stable where sawdust is used instead of straw, it would, of course, be better.—Ferndale. [Whilst we willingly insert any article sent to us which is likely to be instructive to our readers, we must invite our correspondents to confine themselves as much as possible to plain practical facts. Our space has become too valuable to be occupied with needless controversy.—Ed.]

An Easily Made Fumigator.—I have a frame 5 ft. by 4 ft. in which I have kept a quantity of Pelargonium cuttings, and yesterday I noticed that they were being gradually destroyed with green fly. By the following plan I totally destroyed the fly; I got a 2½-in. pot and picked out the whole of the bottom, which then admitted the bowl of a common Brier-wood Tobacco-pipe. This I tightened in with clay, thus making good the bottom with the bowl of the pipe, of course leaving the inside of the pipe open so as to admit a draught of air through the stem left on the bowl, to which I next attached a long india-rubber tube I had by me. I then got a square box, made a hole in the top, so as to admit the small flower-pot and keep it firm. Then a hole through the box on left side, to admit the pipe which was carried through a hole in the end of the frame. I then put an old cornet mouthpiece at the other end of the pipe, into which I blew a gentle current, and thus gradually and evenly filled the frame with smoke. I filled the 2½-in. pot with dry Tobacco sprinkled with a few drops of turpentine, which, when burning, seemed to throw out a nice perfume. When well alight I closed the frame, and of course only blew sufficient air down the tube to keep the frame evenly filled, and at intervals, as I saw the frame clearing. One hour afterwards I took off the light and examined the plants. I found hundreds of flies on the mould dead, not stupified. With a syringe I washed them all out; the plants were then clean and free from any signs of a fly. By filling the frame gradually, the flies run down the plant to escape the smoke, which, of course, fills the top part of the frame first, and rest on the mould in the pot, where the smoke catches them and despatches them. If the frame were filled at once, they would keep on the plant stupified and might not be killed, but this way that I mention does its work gradually and effectively.—A. A.

GLASSHOUSES AND FRAMES.

MARKET PELARGONIUMS AND FUCHSIAS.

Amongst the many nurseries in which plants are grown for market in the vicinity of London few have obtained a better reputation for the production of Fuchsias and Pelargoniums than the establishment at Edmonton—conducted for many years past by the Messrs. Hayes—and which is at all times worthy of a visit, but never more so than early in June, when their large and in all respects admirably managed collections of plants are to be seen flowering in their best form. I visited this nursery about that time, and noted down the names and leading characteristics of the best and most useful kinds of both Fuchsias and Pelargoniums—sorts in every way first-rate for all floral furnishing purposes, and therefore valuable alike to the private grower and nurseryman. Commencing with the Fuchsias, the first variety to claim special notice on entering the large and admirably constructed span-roofed structure in which the plants are allowed to bloom and finish off preparatory to being sent to market was a very fine and free double red variety called Monstrosity. This sort has a good habit, does well in the small pots indispensable to market growers, and the foliage is also handsome, large, and of a deep shining green colour. An unnamed double white kind of very excellent habit was also in grand condition. Another very remarkable double kind called Champion of the World was particularly striking, the blossoms being deep red and maroon, and of altogether uncommon size. Its flowering habit is free, and the growth decidedly inclined to ramble; and, being very vigorous, it will doubtless make a very excellent subject for conservatory decoration. Some of the plants we saw of it at Edmonton had been trained to the iron braces of the roof, and although only in small pots, they had covered their supports, and were literally loaded with festoons of graceful and exceptionally large flowers. I feel sure that all who have to provide for the ornamentation and covering of bare pillars, walls, &c., in conservatories would do well to grow this really fine Fuchsia. Amongst the single varieties, Clipper is very noticeable, being a distinct advance in every way on the well-known and excellent red kind, and in its

day one of the best, viz., Prince of Orange. Sir Bartle Frere is also a capital sort. It has a dense dwarf habit, and large red and violet flowers; one of the very best. Amongst light-coloured varieties Mrs. Marshall and Lady Heytesbury still maintain their reputation; but a light sort named Starlight bids fair to successfully dispute the position which the two first-named kinds have so long held. It somewhat resembles Lady Heytesbury in habit of growth and shape of flowers, but still it is quite distinct and in every way a really admirable kind.

Adjoining this house of Fuchsias are numerous structures devoted to the culture of Pelargoniums, and from amongst a large number of kinds in good flower we selected the following varieties as being in every way first-rate:—Princess of Wales, an extremely free fine dwarf kind—blooms in perfection even in 3-in. pots. In colour it is light rosy flesh, with a white ground, and elegantly fringed. Lady Isabel, a really grand Pelargonium, is bright rosy-lilac in colour, with dark spots, truss large, and habit most robust. Nellie Hayes, light ground colour, with black blotch; profuse bloomer, free and fine. Black Prince, light-edged, black-maroon; very effective and free. Delicatum, a charming kind, light peach, coloured with dark blotch; very free, and without doubt a kind possessing sterling qualities. Lady Blanche, an improvement on the well-known white sort Duchess of Edinburgh. Mrs. John Hayes, a valuable kind; colour pinkish-white, with a crimson and maroon blotch. Maid of Kent, a fringed white kind of first-rate excellence. And La Grande and Prince of Wales, fine bright high-coloured flowers of the greatest excellence. The varieties just enumerated were all seedlings raised in the Messrs. Hayes' nursery; and we can confidently recommend them to the notice of all lovers of the Pelargonium. They are one and all genuine sorts of the market type, and therefore can be grown to perfection in the regulation 4½-in. pot, and are thus available for all decorative purposes.

H. B.

CULTURE AND PROPAGATION OF CHOROZEMAS.

Scarcely any of the Australian plants are brighter, more useful, or more easily cultivated than these Pea-flowered, slender-growing shrubs. Being of free growth, which, when matured by full exposure, is certain to be abundantly floriferous, not much subject to insect attacks, and thriving as they do in a conservatory where most of the ordinary hard-wooded plants would quickly die, Chorozemas are well worth attention. If at any time a specimen becomes leggy or naked at the base, it may be pruned back, placed in a gentle heat, and it soon breaks into young growth. They are easily propagated from cuttings of half-ripened wood in sandy soil under a bell-glass in gentle heat. Seeds also, either imported or home-grown, soon vegetate if good, and make pretty little plants. They will succeed either in peat or loam, or in a mixture of the two, with sand added in proportion to the nature of the soil. In the matter of soil for this and many other plants, I think it is not so well to tie ourselves down too tightly to any particular compost, as all of us are more or less influenced by surrounding circumstances. There are many plants usually grown in peat that might be better grown in good loam than in inferior peat; and where the loam is good and the peat inferior or expensive, I should certainly prefer the loam. There are some plants, of course, that cannot be grown and kept in health in loam. Heaths, for instance, and other fine-rooted plants thrive only in peat. But there are a good many different kinds of loam. The best kind for New Holland plants has a bright colour and a soft, silky feel when handled, and if used in a fibrous condition, with sufficient sand added to make the water pass through freely, the growth will be firm and short-jointed and less likely to run up weakly than when potted in a lighter compost.

One of the good qualities of this race of plants is blooming freely in a small state and their long period of duration. Young plants may be pushed on in spring in a warm greenhouse or early Vinery. All shoots showing a tendency to run away should be pinched back. In this way a good thick base will be made that will in time form a handsome specimen. Some support will be required for the slender shoots as they advance in growth, and there is nothing neater or better than thin deal sticks painted green. These can be made in bad weather, and have a little green paint rubbed over them. Not one more than is necessary to give the requisite support to the plants should be used, as in themselves they constitute an ornament. The plants must not be given too much heat in spring. After pruning, a little warmth and a closer atmosphere will be beneficial for a few weeks, but they should be cooled down early, and be placed in a sheltered situation in the open air early in July, where they may remain till the middle of September. Those plants of such kinds as cordatum splendens, that are started in a little heat in spring, to get the growth made early, will commence to flower in October, and will prove exceedingly valuable and reliable when other flowers are scarce. Any one having a conservatory to keep gay in autumn and winter should have at least half-a-dozen good-sized specimens to help out the Chrysanthemums, Salvias, and other plants. The following include some of the best kinds: cordatum splendens, Lawrenceanum, Henchmanni, and varium nanum, The last is a dwarf kind suitable for a small house.

H.

Dracæna fragrans.—This is one of the noblest of fine-leaved plants for the greenhouse or conservatory. It succeeds best when planted

Fragrant-flowered Dracæna (D. fragrans).

out in a border of sandy loam enriched with rotten cow manure, in which position it will often flower freely. Its flowers are remarkable for their fragrance, but the plant is well worth growing for its foliage alone. We have seen very handsome plants of it grown in comparatively small pots for room decoration.

Fuchsias for Pillars and Rafters.—The old Fuchsia corallina does remarkably well trained up rafters like Vines. Souvenir de Chiswick and Venus de Medici are also two other old favourites that are well suited for the purpose. Plant them out in rich, well-manured compost, and train them up in the form of a single stem, removing all laterals until they are as high as required. After they have bloomed in autumn prune the laterals close in, just as is done in the case of Grape Vines, and start the plants afresh in the spring by applying a little heat and syringing them with tepid water. So treated they will bloom profusely, and are among the most beautiful of all cool conservatory plants. When so grown, cut branches of some of them are very useful for room vases.

Sowing Flower Seeds.—Most hardy annuals, biennials, and perennials will do better if sown in August or September than if the sowing be delayed till spring. Not only is it the most natural time for sowing, but the land is usually warmer and the seeds lie a shorter time in the ground before germinating, and they consequently produce a stronger and healthier plant, and they are less liable to be eaten off by insects; and, lastly, much time is gained, for, instead of sowing the seeds in March, you have young hardy plants ready to put out. Seeds of hardy biennials and perennials are best sown in well-drained ground, arranged in 4-ft. beds, with a track or alley 1 ft. wide between them, for the convenience of weeding, thinning, and lifting the plants. The soil should be in a well-pulverised condition, and if too dry should be well soaked with water twelve hours before sowing. They may either be sown broadcast or in shallow drills across the beds; the latter plan is the best, because it gives facilities for stirring the soil between the rows of young plants. The drills can be made by pressing a 4-ft. rod or straight edge into the soil the required depth, according to the size of the seeds; ½ in. will be deep enough for all small seeds, and when the seeds are sown thinly in the drills, cover lightly with finely sifted soil. If the weather be hot and dry, shade by laying mats, or similar coverings, on the ground. If the patches be small, Rhubarb leaves will answer the purpose very well, and they are usually at hand; they must, however, be removed as soon as the young plants appear. When annuals are sown in the spring in the borders where they are intended to remain, they are usually sown too thickly, and the thinning delayed too long, consequently they never attain their proper development—the flowers are poor, the growth weak, and the whole plant short-lived. This is the main cause why annuals are in many places so unpopular. If sown on good land, and such plants as Nemophilas, Saponarias, &c., thinned out, so that every plant has not less than half a square foot to grown in, they would present a much more satisfactory appearance than they usually do.

Giant Candytuft.—We have received from Mr. Cuthbertson, of the Public Park Nurseries, Rothesay, remarkably fine spikes of a Rocket Candytuft, which he calls Giant Snowflake. The flowers are pure white, and form spikes 4 in. or 5 in. long and 6 in. or more in circumference. Such a fine hardy plant which can be easily raised from seed in autumn or spring cannot be too well known.

Begonia Seed.—A great source of failure in obtaining plants arises from unsound seed. Very few varieties seed under glass, but if planted out it may be had in abundance. To test it before sowing place it in the palm of the hand and blow on it very gently; if it be dissipated like dust it possesses no vitality; you place it on a sheet of letter paper, and if it rolls about like Poppy seed when touched, it is all right. Unsound seed lies dead, like a pinch of snuff.—T. B.

The Great St. Bruno's Lily (Antheric um Liliastrum).—This is one of the finest of hardy plants, and one of the easiest to grow. It only requires to be planted in deep free sandy soil, when it will grow vigorously, and in early summer throw up spikes of snowy white, Lily-like blossoms 3 ft. in height. In dry soils a good mulching with rotten manure would be a great help to it, and in early spring the plants must be examined for slugs and caterpillars, to attacks of which they are rather liable. In Mr. Parker's nursery at Tooting there was a good display of this Lily in June last, from which plants our illustration was prepared. Propagation of this Lily is effected by division of the roots in autumn, which is the best time to plant, or it may be raised from seed when it can be obtained.

Worms in Pots.—It is stated that these can always be got rid of by using for the plants water to which a tenth part of grated Horse Chestnut has been added. Under this treatment, it is said, the worms must either fly or die.

Removing Smell from Liquid Manure.—A small portion of air-slaked lime put into a liquid manure tub will remove the smell, and when the liquid is applied to the soil will destroy worms and slugs.—F.

ANSWERS TO QUERIES.

2680.—**Plants to Flower in Winter.**—Early Cyclamens may flower all through the winter if enough warmth be provided, as also will Chinese Primroses. These are the best of greenhouse flowering plants. Chrysanthemums will bloom well nearly up to Christmas, and these may be succeeded by Christmas Roses in pots; early bulbs, such as Crocuses, Snowdrops, Scillas, and Van Thol Tulips, other Tulips and Hyacinths succeeding. Such hard-wooded plants as Genistas, Deutzias, and some Heaths will also bloom very early if pushed on for the purpose. There are, however, but few plants that bloom naturally during the dull winter months, as a mere cool greenhouse does not much differ from the temperature out-of-doors. Auriculas, Polyanthuses, and Pansies will also bloom early if housed under glass all the winter.—D.

2668.—**Uses of Frames.**—There are many uses to which frames may be put in the winter, but the most profitable must depend upon the wishes of the owners. A large number of half-hardy plants may be housed in them, or even hardy plants in pots of such things as Pansies, Auriculas, Polyanthuses, Violets, Primulas, &c., or they may be filled with vegetable produce, such as Cauliflowers sown late in October to stand the winter, or Lettuce sown about the same time, or some Peas may be sown on pieces of turf for transplanting into the open ground early in March. Radishes may be sown in them quite early, or Rhubarb may be lifted into them for early forcing, or Seakale or Asparagus. In the way of flowers plants of Neapolitan or other double Violets may be forced or even simply grown in them, or seeds of hardy annuals for transplanting in the spring may be sown early in November. Many kinds of half-hardy bedding plants, such as yellow Calceolarias, may also be housed in frames for the winter.—D.

2673.—**Exhibiting Dahlias and Asters.**—Although it is the rule to exhibit cut Dahlias and Asters on boards in which are fixed at proper intervals zinc water-tight tubes, there is really no reason why these flowers might not be as easily shown in Moss. We saw but the other day a fine lot of Carnation blooms shown on a bed of neat green Moss, and thought they looked very charming. A shallow box, say 3 in. deep inside, and painted green, will do admirably if filled with Moss, and surfaced over with some that is specially green and neat, and well pressed down. Some small tubes to hold water for the flower-stems should be fixed in the Moss at proper intervals; but if the Moss be damp and the weather not too hot, even these may be dispensed with, as the Moss will assist to keep the flowers fresh for some time.—A. D.

2672.—**Plants on Graves.**—For the winter planting of a grave garden surrounded by a white stone plinth nothing would be neater than an edging next the plinth of Sedum lividum, dense green, about 4 in. wide, and inside that the rest carpeted with Sedum acre aureum and the golden-tipped Stonecrop; this is a lovely winter and spring carpet plant. Some half-dozen of neat little green and variegated Coniferæ—Cupressus or Thuja—that might be obtained from any nurseryman, might be planted before the carpet plants are put out; this would need but the most trifling attention all through the winter. We employ Sedum lividum, glaucum, and acre elegans, with Sempervivum californicum and Echeveria secunda glauca, Herniaria glabra, and Veronica repens, both dense green carpet plants, on graves in the summer with excellent effect. The result is simple and pleasing and, not least, permanent. A few of the larger Sempervivums are useful as dot plants in the arrangement.—A.

2674.—**Tulips for Show in April.**—As Tulips bloom naturally in the month of April, it is not necessary to plant them in pots unusually early to secure their blooming in the first week of that month. The month of November is an excellent time for such purpose, and to make a good show six or seven bulbs should be put into a pot that measures 8 in. across the top, and be buried about 2 in. deep; the soil should be good and fairly firm. The pots may be stood at once in a cold frame, not exposed to the sun, and be covered with 2 in. or 3 in. of Cocoa fibre refuse to keep out frost. In that position they might remain until the leaves are seen peeping through, when the pots should be removed either into a sunny frame or into a greenhouse, and be pushed on or retarded just as the promise of blooming may be shown.—D.

2679.—**Hydrangeas not Flowering.**—The Hydrangea is naturally a very free flowering subject, but requires at times a maximum of light, a free admission of air when grown under glass, and to be freely exposed to the sun during the summer months. The great point is to secure good, strong, healthy, but not crowded growths, and thoroughly mature them; success is then certain. Any weak shoots should now be thinned out, leaving from four to a dozen or more, according to the size of the specimen. Place the plants now in the open and where they may enjoy the fine influence of sun and air. Keep them well watered, and about the latter end of October place them under cover in a cool house. Keep them just moist during the winter months, and at the turn of the year prune each shoot back, leaving only two eyes to each one. By March growth will commence, when the plants must be accorded a light position; at the same time, if the pots are full of roots, shift them, using a compound of good loam and rotted manure, ramming it well in. Give plenty of air, but avoid chilling draughts. In a cool house by the middle of May the bloom-buds will be showing; a sharp look out must then be kept for green fly, which is easily stopped by dusting with Pooley's powder. Towards the latter end of the month place them in a sheltered situation in the open air, removing them later on to any desired position.—J. C.

The Great St. Bruno's Lily (Anthericum Liliastrum); a hardy plant, suitable for large or small gardens; flowers white.

2627.—**Best Climbing Roses.**—Some of the best Roses for indoor culture are Maréchal Niel, Madame Falcot (yellow), Safrano (fawn), Catherine Mermet (flesh), Duchess of Edinburgh (bright pink), Souvenir d'un Ami (rose), and Cheshunt Hybrid (carmine). For outdoors you may take climbing Victor Verdier, climbing Jules Margottin, Gloire de Dijon, and any of the Ayrshire, Boursault, or evergreen kinds, such as Adelaide d'Orleans, Felicité Perpetuelle, Dundee Rambler, and Ruga.—C.

2628.—**Mildewed Strawberries.**—The mildew is a fungoid disease which is fostered by warm, moist weather. In glass structures during the forcing season it often appears, but is easily stopped if the plants are dusted with flour of sulphur as soon as the fruit is fairly set. In the open air it will be much more difficult to deal with, owing to the liability of the sulphur being washed off by heavy rains before it has had time to do its work. The best advice that we can give is to thoroughly syringe the under surface of the foliage and the fruit as soon as the latter begin to swell. When the fruit is ripening the sulphur is easily washed off again.—J. C.

2624.—**Ferns for a Vinery.**—Any of the following kinds would be suitable: Adiantum cuneatum and formosum, Pteris serrulata, P. cretica albo-lineata, P. scaberula, P. arguta, Polystichum denticulatum and proliferum, Lastrea glabella and decomposita, Asplenium bulbiferum, flaccidum, and præmorsum, Nephrodium molle, Platyloma rotundifolia, Lomaria gibba and lanceolata, and Doodia caudata and lanulata. For hanging baskets the following species are well suited: Davallia canariense and bullata, Niphobolus Lingua, Adiantum Capillus Veneris, Platycerium alcicorne, and Woodwardia radicans. All these may be grown well in a

shady structure from which frost is excluded. Ferns, as a rule, do very well under Vines, the filtered light which they there get being just what they require, and by the time that the days get short the foliage falls and allows them during the dull season to feel its full influence. All that the grower has to do is to create atmospheric moisture in hot weather by frequently damping down the paths and stages, and attend carefully to the watering. Ferns should not be over-watered, but should never be allowed to remain dry at the root.—J. C. B.

2623.—**Plants for Heated Conservatory.**—If Palms are to form a feature in the house, it will be necessary to employ such plants for the rockwork as demand similar atmospheric conditions. Nothing can be more satisfactory for planting on rockwork than the many beautiful species of Ferns which thrive in such situations. The following kinds are all well adapted for the purpose: Davallia dissecta, canadensis, and bullata; Doodia aspera and lanulata; Adiantum Capillus Veneris and cuneatum; Niphobolus Lingua; Platyloma rotundifolia; Pteris serrulata and crested variety, P. cretica albolineata, Nephrodium molle cristata, Microlepia anthriscifolia, and Hypolepis distans. These are all beautiful kinds of moderate growth. With them might be associated Panicum variegatum, Tradescantia zebrina, Isolepis gracilis, and various kinds of Selaginellas. Palms may consist of Chamærops excelsa, Corypha australis, Latania borbonica, Rhapis flabelliformis, Seaforthia elegans, and Areca lutescens. Roses may be grown in the same house, and if trained to the roof, would give just the desired amount of shade to the Ferns.—B.

2625.—**Uses of a Frame.**—A cold frame may be made to shelter a variety of tender plants during the winter, but in that case it must be made frost-proof. This is best effected by driving in some stout stakes all round the frame, about 1 ft. from the boards or brickwork, and stuffing the interstices with Fern or some such dry material. A slip of wood should be nailed to the top of the stakes, so as to hold them all firmly together. This will effectually hinder frost from entering the sides; and if the glass is efficiently covered, there will be but little danger of the inmates suffering even during the most severe weather. The bedding plants may be cleared out and placed in a sheltered situation by the beginning of May, when the frame will be available for raising a number of beautiful annuals, such as Asters, Ten-week Stocks, Balsams, Phlox Drummondi, Zinnias, &c.—these to be planted out when large enough in the open air. When the annuals are thus disposed of, the frame may be planted with Cucumbers, which will yield up to the time it is necessary to think of again providing for the safety of the tender plants.—J. C., *Byfleet*.

2632.—**Gardening in Town.**—For a north wall nothing can be better than Ivy, of which may be taken the common Irish, Algeriensis, and the large Clouded White. The south wall may be given up to Pyrus japonica and P. Pyracantha—the one beautiful in spring, the other brilliant with its bright berries in the autumn. There are no two better flowering wall shrubs than these for a town garden. On the north border might be planted flowering bulbs of many kinds, such as Daffodils, Snowdrops, Crocus, &c.; also Primroses and Polyanthus, Myosotis dissitiflora, and London Pride Saxifrage. We would also try a few of the common kinds of Lilies, such as the Tiger, the Orange, and the old white, carpeting the ground round them with Periwinkles of various kinds, using both the plain leaved and variegated varieties. In the more sun-secluded corners make up a bed of good soil for hardy Ferns, which ever delight by their freshness and verdure. In the more open sunny parts of the garden try Daisies, Pinks, Violas, and Pansies, such as bloom throughout the summer, Arabis albida, Alyssum saxatile, Aubrietia purpurea, and Anemone japonica. Wallflowers would also probably succeed, and may be seen anywhere. The old Honesty is a gay and cheerful plant, but should be sown in March to bloom the next year. Amongst other likely subjects may be be mentioned Sunflowers, to be sown in March; Silene pendula, to be sown now to bloom in spring; the hardy annuals, Clarkia pulchella, Collinsia bicolor, and Nemophila, to be sown in September; Larkspurs and Godetia Lady Albemarle in March, and climbing and dwarf Nasturtiums and Convolvulus in April. For beauty of foliage may be taken Cerastium tomentosum and Stachys lanata, two white-leaved plants; Euonymus radicans variegata, a pretty little shrub; and Rhus glabra laciniata. One of the best of evergreens for a town garden is the common Euonymus. Aucuba japonica is also suitable. The plants above enumerated are all likely to thrive in the situations mentioned. At the same time it is a real matter of difficulty to recommend plants for such places. The unfavourable conditions are very great; and then again soil and situation generally have to be considered. Those who have such gardens to deal with must expect failures; they must try, try again until they find out what will thrive best, and then they should record their experiences, both failures and successes, for the benefit of others similarly situated. Town gardening is yet in its infancy.—J. C., *Byfleet*.

2677.—**Fever Gum Tree** (Eucalyptus).—We cannot understand the Eucalyptus going off in the manner described. It is an extremely easy plant to grow. When the seedlings are large enough to handle, pot them carefully into small pots in a compost of well-sanded leaf-mould and loam, and place them in a close frame or in a warm corner of the greenhouse. Water carefully, giving air when the weather admits, and shade from hot sun. Supposing them to be potted off in April—the best time—by the end of May they may be exposed to sun and air. As the pots get full of roots shift carefully into the next sized pot. Keep them under glass until the middle of August, and then place them in a sheltered situation in the open air until the beginning of October.—J. C. B.

2629.—**Vallota purpurea in Windows.**—If the Vallota bulbs are large enough they will probably bloom this next autumn. The Vallota requires three seasons' growth to gain the requisite strength. You probably gave the manure water too strong. Give a little now; it will benefit them, but let it be very weak. The proper way to use liquid manure is to give little and often. Next April or May if your plants are healthy and the pots quite crammed with roots, shift them into the next sized pot in loam and leaf-mould or loam and peat.—J. C. B.

2626.—**Potatoes Diseased.**—The peculiar turning brown in the leaves of your Potatoes is a common failing of the Early Rose and other American sorts, and it is by no means improbable that yours are suffering from the same affection. There are two probable causes for this. In the first place, the planted sets might have been partially diseased, and the plants are but exhibiting that kind of sickness. It is as probable that the plants affected were cut by late frosts, and the result now seen is but the product of that attack in the spring. The haulm of many of the American kinds is more tender than that of English sorts, and thus the wider appearance of this rust in the Rose and other sorts. The manure does not probably affect the Potato, but sawdust is not a good thing for the soil, as it is apt to breed various fungus growths. Try next year some other kinds of Potatoes and use some guano dressing only or other artificial manure, employ no stable manure, trench the toil deeply, and ridge it up for the winter.—A. D.

2667.—**Sowing Potato Seed.**—This year Potato Apples or seed-pods are abundant on many kinds, and these must be gathered as soon as they begin to colour or become purple. They should be laid on a shelf for the winter, and in the spring it will be found that the flesh of the seed-ball has decayed, and only the clean seed is left. This may be sown at once in pots or pans; and when the seedling plants are large enough, some may be transplanted into the open ground, and others may be grown in pots or boxes under glass. This latter is a useful precaution if the disease be prevalent, as in such case the whole of the plants in the open ground may be destroyed before any tubers are formed, seedling plants in the open ground being longer in forming tubers than plants grown from sets. If kept in pots where the root space is confined, then the plant growth is less robust and tubers are formed earlier. We have now growing in the open ground a batch of seedlings the haulm of which is 2 ft. in height and very strong, whilst others of the same cross in pots will soon ripen off their tubers. Thus, whatever may happen, some seedlings are saved in any case. It may, however, interest you and other readers to learn that little benefit in the way of producing new kinds will result from the growth of natural seedlings. As a rule, these do but reproduce the parent kind. Really good new kinds can only be obtained by intercrossing of sorts, and that is done in this way:—Flowers of one kind are gathered and held, one at a time, with the pollen cases projecting between the two forefingers, with the nail of the thumb placed just beneath. A sharp nick is given to the pollen cases with the point of a small penknife, and the pollen will fall out upon the thumb-nail. If one flower does not give enough then others may be tried. When this is done the pollen may be conveyed, still on the nail, to the flowers of the sort to be fertilised. Two blooms are enough, and the projecting stigma is gently drawn across the nail to take up the pollen. The flowers are then marked with a label and a stake and left until the pods are ripe. We have this year made about twelve such crosses—several with Magnum Bonum and other fairly disease-resisting kinds. We have also employed the new Woodstock Kidney, a kind that produces pollen freely, upon Beauty of Hebron, a first-rate early American sort, and with this we hope to obtain some first-rate early seedlings. Your difficulties begin when your seedlings increase, after two years' growth, as it requires four years' trial to make a suitable choice of the best, and it is not easy to afford space to grow them all.—A. D.

2458.—**Properties of the Auricula.**—The properties of the Auricula are thus defined by a good authority: 1. Pip should be circular, large with petals, equal, firm, fleshy, smooth at the edges, without notch or serrature, and perfectly flat. 2. The tube should not exceed one-fourth of the diameter of the pip; it should be of a fine yellow or lemon colour, perfectly round, well filled with the anthers or thrum, and the edge raised a trifle above the paste or eye. 3. The paste or eye should be perfectly circular, smooth, and of a dense fine white, without crack or blemish, forming a band not less than half the width of the tube, and encircling it. 4. The ground colour should be dense, whole, or forming a perfect circle next the eye; the brighter, darker, or richer the colour, the better the flower, but if it be paler at the edges where they are parted into five, it is a fatal aspect. 5. The margin or outer edge should be a clear unchangeable green, grey, or white, and be about the same width as the ground colour, which must in no part go through to the edge. The stem should be strong, round, upright, elastic, bearing the trees upright without support, and from 4 in. to 7 in. high, so as to come well, but not too high, above the leaves. In the alpine class the flowers have no paste, and, owing to this fact and the disposition of the foliage, are better adapted for growing in the open air.—J. C.

2682.—**Petroleum Stoves.**—In answer to "G. P." respecting the use of a petroleum stove for his greenhouse, I beg to state that I have a house of about the same dimensions for growing Geraniums, Fuchsias, Ferns, &c., and that I procured one of Heap's & Wheatley's patent one-light petroleum stoves for the purpose of keeping out the frost in winter, and it did so admirably during very severe frosts, and I found no injury to my plants from the use of it. It only costs about a farthing per hour in oil, and after being properly filled and lighted requires very little attention. Its cost when new is 38s., and if "G. P." is desirous of trying one of these, I will supply him with mine, as I have no further use for it, having put a flue into my greenhouse in which I have planted Vines since. I will take 20s. on rails here, and will guarantee it in good condition and ready for use.—W. Parlour, *Boroughbridge, Yorkshire*.

2622.—**Jessamine not Flowering.**—Perhaps the plant in question has not yet become thoroughly established. If it is making free growth it will in all probability flower next year. The situation is favourable to its well-being.—J. C. B.

2667.—**Sowing Potato Seed.**—Save the Potato fruits or balls from the best varieties, and when ripe squeeze them in a basin of water to get rid of the pulp. It will require several washings to do this, and care must be taken in changing the water that none of the seed is lost. Strain through a coarse cloth, and place in an airy situation. When quite dry, separate the seeds as much as possible, and keep them in a dry place till next March or April, when sow in shallow drills in the open ground about 7 in. or 8 in. apart. Each seed will produce one Potato, from the size of a small Pea to a blackbird's egg,

and each of a different variety. If anything new or desirable appears, it must of course be propagated from the small single tuber. The last time I sowed Potato seed the little tubers were affected with the disease worse than the planted Potatoes in the garden.—J. C.

2677.—**Fever Gum Tree** (Eucalyptus).—I had six or seven of these plants growing in a 9-in. pot for eighteen months in a cold greenhouse. I put them out in the open ground in rather a stiff soil of a clayey nature (that was a year ago last May), with a little coal-ashes round the foot of the stems; they have stood the severity of last winter. The leading shoots and the branches were cut and injured by the frost, but now they are growing vigorously. The leading shoots have made a growth this summer of 2 ft. 6 in., and the side-shoots 2 ft. The height of my largest plant is 6 ft. 6 in. Any good garden soil will suit them to grow in pots or in the open.—T. FRIPP.

2676.—**Drooping Fuchsias.**—Corallina and penduliflora are two kinds well fitted for this purpose—the former is perhaps the best of the two.—C.

2683.—**Roses on Trees.**—One of the strong-growing evergreens, such as Leopoldine d'Orleans, or Adelaide d'Orleans, or one of the Ayrshire, such as Dundee Rambler, would, we think, be most suitable.—B.

2666.—**Hardy Perennials.**—We consider it much too late to sow perennials generally; the young plants do not attain sufficient strength to effectually resist the severities of a hard winter. Columbines (perennial), Larkspurs, Aubrietias, Violas, Pansies (both fancy, show, and bedding), Wallflowers, and Arabis may be sown with a fair prospect of success. April is the best time for sowing this class of plant.—B.

2675.—**Climbers for Scotland.**—The front of a house might be furnished quickly and prettily with the gold and silver-leaved Ivies and Clematis Jackmani, or lanuginosa hybrids intermixed. The Ivies would cling to the wall, and the Clematis should be trained thinly over it. The Virginian Creepers are very hardy, and Veitchi is very pretty, and clings to the wall like our own Ivy, but they are all leafless in winter. The following are also very hardy and evergreen: Cratægus pyracantha, Pyrus japonica, Cotoneaster microphylla, and Lonicera grata.—E. H.

2662.—**Calceolarias Diseased.**—The disease that kills the Calceolaria in the way described is of a fungoid character, the seat of which is mainly in the bark, at or about the collar. The only remedy is change of soil, with cool treatment in winter to the young stock to secure strong healthy plants to turn out in spring.—E. H.

2663.—**Vegetable Marrows Dying Off.**—The absence of sunshine has made the large leaves of the Vegetable Marrow soft, flaccid, and especially liable to mildew and blight, and the blossoms partake of the same weakly character. Keep the growths thin and pegged out, stopping the leaders if running away too fast. In a small degree the male blossoms weaken the plant, but their presence is necessary to set the fruit if you should require seed.—E. H.

2670.—**Cypripedium barbatum nigrum.**—If the plant in question is healthy and vigorous it will probably now need to be fresh potted. Shift into the next sized pot or pan as the case may be, filling the same half full of drainage and using a compost of the best fibrous peat, with which may be mixed a little chopped Sphagnum and crushed charcoal or small pieces of crocks. Keep close and moist, syringing once or twice a day in hot weather, and shade from bright sunshine.—C. B.

2630.—**Propagating Virginian Creepers.**—Take cuttings of the current season's growth as soon as the leaf falls. Cut them to three eyes, and insert them firmly in light sandy soil. The pots should be kept in a cool situation during the winter, and should be removed to a shady place by the time that the sun gets power. The best way to strike them is to insert them firmly in a north border, where the sun comes but little in the spring.—C.

2631.—**Cut Roses in Water.**—The quality of the water may exercise an influence upon the duration of the blooms. Try a little charcoal in it. This is supposed to exercise a beneficial effect.—B.

2681.—**Strawberries Placed in Heaps by some Invisible Agency.**—The invisible agents who carry off your Strawberries are no doubt either mice, rats, or squirrels. Birds do not store fruit, but eat their fill as they go. Squirrels being naturally frugiverous animals, will store fruit that may be accessible, and rats and mice will ofttimes do the same. If squirrels or rats, small iron gins should be put down; and if mice, any common traps might catch them.—A. D.

2634.—**Eccremocarpus scaber.**—If the roots of the Eccremocarpus are left in the ground all the winter, no doubt the soil is too cold to promote early growth, and therefore it would be best either to lift the roots in the autumn into pots and keep them in a greenhouse, or take cuttings now to make strong young plants to turn out next spring. Also seed may be sown now, and this will produce fine young plants to start early next spring. Your soil may be unsuitable.—A. D.

2682.—**Petroleum Stoves.**—I used an iron petroleum stove called Rippingille's patent, with two wicks each about 4 in. long, all last winter to heat my lean-to greenhouse (18 ft. by 6 ft.), and found that the heat of one wick was quite sufficient to keep out the frost. I did not lose one cutting, or any bedding-out plants. The smell of the oil was always perceptible in the morning, but by giving ventilation during the day, and especially when the sun was shining, I found no ill effects to the plants.—C. J. M.

2669.—**Onion Maggot.**—I don't think there is any certain cure for the Onion maggot, but there are many palliations, among which are salt and soda if used in time. But it is of little use to wait till the Onions are going off rapidly before we apply the remedy. I have had the greatest success with soot and salt—½ in. in thickness of the former, and 1 lb. per square yard of the latter—spread over the surface and lightly forked in about the beginning of February. A further dressing of soot may be given in April in localities much infested with maggot.—E. H.

2684.—**Improving Lawns.**—A very frequent use of the heavy roller and mowing machine will improve the lawn. Newly laid turf often grows very rank the first year or two, but as the land settles down the Grass will get finer; persevere with the roller.—E. H.

2665.—**Rhododendrons not Flowering.**—The situation is a bad one for Rhododendrons—they require partial shade and shelter; the moisture in such a position is sure to do them justice. Can they be moved to some more sheltered situation? They will never be satisfactory where they now are. The situation is, perhaps, too exposed for Lime trees; Poplars would have done better, but the Limes will probably do better, as they gain strength and get well established.—E. H

2641.—**Flies in Rooms.**—I have found Christy's Myocom Fly Gum, which I gave a shilling for at my chemist's, quickly rid my rooms of flies. The moment I opened the box I was besieged with flies eager to get to the contents of the box. Directions are given on the box, so that it is unnecessary to give them here.—FLY CATCHER.

Although the following questions are answered by the Editor, he will be obliged to any of our readers who may think well to answer them again.

2752.—**Temperature for Greenhouse.**—Will you advise me as to the temperature to keep a greenhouse in spring, summer, autumn, and winter? The house contains Vines, Geraniums, Fuchsias, and a miscellaneous lot of flowers.—A BIRKENHEAD SUBSCRIBER. [After the Vines lose their leaves, just keep the frost out. When they start into growth do not let the temperature get below 40°, or over 50°. As spring advances 50° to 55° at night, and 5° higher in the day will not hurt. When May has passed you have only to give plenty of air whenever the weather will permit. Fire-heat at night will not be necessary.]

2753.—**Pansies.**—What should I do now with Pansy plants which flowered all spring and summer, and are very straggling in appearance. [Cut them down.] Also what should I do with young Pansy plants sown this spring, and now forming very small flowers? They have grown into middling sized plants already. I want to have good blooms next year. [Plant them out and keep the buds picked off.] Is it too late to sow fancy Pansy seed to stand out during the winter.—FANCY. [No.]

2754.—**Planting Strawberries.**—I am about to take up my old Strawberry plants: shall I take off the runners now? I am told Michaelmas. Which is right? In some cases there are three or four suckers on one stem. Shall I use them all, or only one, and which one? Would not the one nearest the plant become stronger and better if I were to nip off the others? I want to plant right off; not pot and replant.—BEGINNER. [Take those suckers which are well rooted, and plant in well manured land at once. If there are no rooted runners, peg the best of them to the ground, and let the old plants remain till the young runners are rooted, then separate them from the old plants, lift them carefully with a trowel and plant. One sucker on a stem is sufficient; leave the strongest.]

2755.—**Fruit Trees on Houses.**—Will any fruit trees succeed trained against the wall of a house facing east, thereby receiving the sun's rays till about twelve o'clock only?—XENOPHON. [Late Pears and late Plums would do in such a position.]

2756.—**Fruit Trees for Fence.**—What fruit trees will succeed trained against a wooden fence facing the north?—XENOPHON. [Gooseberries, Currants (red or white), Pears, Plums, and Cherries.]

2757.—**Cactus not Flowering.**—I have a white Cactus which was a cutting some six or seven years since. It has grown well, but has never flowered. Can you inform me of the best way to treat it in order to induce it to flower?—ALTONIAN. [Place it in a sunny window, and give it just enough water to keep it from flagging. When it shows flower water more liberally.]

2758.—**Young Quick Hedges.**—*G. W. R.*—Unless these are kept cut well in for the first few years they get very bare at the bottom. Being now 18 in. high, we should cut off 6 in. or more from the top, and cut the side shoots in such a way as to let the hedge take the form of a ridge. Always keep the hedge widest at the bottom, or it is sure to get bare.

2759.—**Mildewed Roses.**—*E. M. D.*—Syringe often with water in which has been dissolved a good proportion of flour of sulphur; also when the leaves are wet dust with sulphur through a pepper-box. Give plenty of water at the roots. Keep the shoots thin enough to allow of air and light circulating round them, and mulch with the half-rotten manure or short Grass.

2760.—**Pinks, Carnations, and Picotees**—*H. C. H.*—From the old Clove Pink (Dianthus caryophyllus) originated the Carnation and the Picotee. They are both florists' varieties of that Pink, and although florists laugh at people who cannot distinguish the difference between Pinks, Carnations, and Picotees, it is more than they can do with certainty only by rules of their own making. The Picotee, however, is generally known by its being all one colour, edged or laced with another colour, although there are some kinds without any lacing whatever. The Carnations known as "selfs" are those of one colour only; bizarres are striped.]

2761.—**Tree Fern.**—*G. K.*—The first fronds from a newly imported Tree Fern are often deformed, and rot off. Keep the stem of the plant moist with the syringe, and when good roots have been formed you will get good fronds.

2762.—**Hoyas.**—*R. P.*—The best kind is H. carnosa, which is best planted out in a warm greenhouse in loam and brick rubbish, with a little rotten cow manure added. H. bella may be grown in pots in any ordinary greenhouse, but is better in a warmer temperature.

2763.—**Magnolias against Walls.**—*W. A. S.*—They require deep sandy soil, a good mulching with rotten manure in summer, a soaking of water during severe drought, and, if possible, a slight protection such as would be afforded by a boarded coping.

2764.—**Plants Losing their Flowers.**—*Working Man.*—Plants bought from a nursery and placed in a window often lose their blossoms and buds. It is better to buy the plants in a young state and grow them in the window. Plants lifted out of the ground and potted should be placed in the open air in a shady place for a few days before being put in the window. Give all plants in windows all the air and light possible and keep them clean.

2765.—**Malformed Roses.**—*R. B.*—Cold winds in spring and insects often cause malformed Roses, but more often it is a freak of Nature, the cause of which cannot be accounted for.

2766.—**Vine Leaves Turning Brown.**—*Birkenhead.*—You do not say what state the Grapes are in. If they are ripe the leaves are sure to begin to turn yellow now. If, however, the Grapes are still green, something must be wrong.

2767.—**Draining Seed Pans.**—*A Learner.*—It is of course impossible to drain seed pans without they have holes in the bottom. Either get some of this kind, or make a good hole in the bottoms of those you have. Place over the hole a piece of broken flower-pot hollow side downwards, and over this put ½ in. of crocks broken to the size of Peas—bricks will do, or even ashes sifted; over this put a layer of Cocoa-nut fibre, flaky leaf-mould, or Moss, and then put on your soil.

2768.—**Ants in Cucumber Frame.**—*Subscriber.*—Dust a little Scotch snuff on the surface or a little of Pooley's Tobacco Powder or even soot, being careful not to put any on the foliage.

2769.—**Frame for Violets.**—How should I make up a frame for winter Violets?—ALVASTON. [Place the frame on a bed of leaves, lawn mowings, and stable litter. Then fill the frame full of half-rotten leaves to within 12 in. of the glass. Then put on 6 in. of soil, and plant the plants dug from the open air with good balls of earth attached to them. Water and keep close for a few days.]

2770.—**Double Wallflowers.**—*Creditonia.*—These are hardy perennials, and if cut back slightly after flowering will form bushy and floriferous plants the following year.

2771.—**Hardy Campanulas from Seed.**—*Miss A.*—Most of these can be raised from seed sown now or in spring. Sow in shallow boxes or pans of fine soil. Place them in a shady situation in a frame or under a handlight if you sow now, but if you sow in spring a little warmth must be given to get the seeds to germinate. The seed may be obtained at the principal seed shops. We cannot recommend any particular tradesman.

2772.—**Virgin Cork.**—*Ivy.*—Consult our advertising columns.

2773.—**Answering Questions.**—*Ernest H.*—All questions are inserted or answered in GARDENING free of charge if written separate on one side of the paper only. Three questions at one time are as many as any one should expect answered.

2774.—**The Garden of England.**—Which shire or county is called the Garden of England?—L. BUCKINGHAM. [Kent.]

2775.—**Warming a Conservatory.**—*Cotton.*—You cannot do better than have a saddle boiler fixed near the chimney which you wish to utilise, and two rows of 4-in. pipes all round the house. This in the end you will find the most economical way of heating, although its first cost may be greater than other methods of heating. If a good draught is secured for the fire you may with a saddle boiler burn all the cinders, and even ashes from the house; also the very small coal.

2776.—**Red Spider on Vines.**—*J. H.*—A dry atmosphere and insufficient air causes this. Vines which are grown with plenty of air early in the season make thick, firm leaves, which resist the spider to a great extent, but their leaves, such as are grown in a close atmosphere, are sure to suffer. If the Grapes are cut, well syringe the Vines with cold water, and wet every portion of the house. The house may be kept shut up for a day when the sun is shining brightly provided the whole surface inside the house is kept thoroughly saturated with water. After this throw open the house night and day, and get the wood ripe for next year, and in winter have the house whitewashed, painted, &c., and the Vines thoroughly cleaned.

2777.—**Herbaceous Calceolarias.**—*Horological.*—When large enough to handle, prick them out singly into small pots, shifting them into larger ones as necessary, keep them in a sunless situation till the end of September, giving enough water to keep the soil moist. As you have no frame, you must put them in a window—not a sunny one—and give them all the air and light possible, and fumigate them occasionally for green fly.

2778.—**Geraniums Growing Straggling.**—*E. A H.*—Use good turfy loam and sand made tolerably firm in the pots, and keep the points of the shoots pinched out. This, if they are not in too shady a place, and they receive plenty of air, and are near the glass, will induce them to grow bushy and flower profusely.

Notice.—SENDING PLANTS TO NAME.—We have lately received many boxes of plants to name without their having attached to them the slightest clue whereby we could tell by whom they were sent. We would remind our readers that all boxes of plants should contain a note respecting them, otherwise it is impossible for us to deal with them.

Names of Plants.—*A. W.*—Fuchsia Meteor.——*T. R.*—1, Aspidistra lurida variegata; 2, Red Valerian (Centranthus ruber.——*R H.*—We cannot name Apples from a single specimen, and that a very poor one indeed.——*W. P.*—The light Fuchsia is Rose of Castile, the dark one Prince of Orange.——*Gunnersbury.*—The Flame Nasturtium (Tropæolum speciosum); seed or division of the root.——*Erin.*—Mesembryanthemum of some kind, which we cannot say without seeing flowers; it requires open sandy soil and a sunny situation.——*Connaught.*—Napoleon Bigarreau.——*R. B.*—Campanula Trachelium.——*Crazula.*—The common Corn Marigold (Chrysanthe-

mum coronaria.)——*Miss F.*—Campanula fragilis. Loam, leaf-mould, sand, and a few pieces of limestone or brick rubbish, plenty of air, light, and water.——*W.*—1, cannot be recognised; 2, Sibthorpia europæa.——*Rusticus.*—We cannot name Pansies.——*Ted.*—We got your letter, but no box.——*W. R. T.*—Tropæolum speciosum.——*J. I.*—No plants enclosed.

QUERIES.

2779.—**Culture of Coleus.**—Will some one give me any information of how to manage these plants: the heat required during the winter? the kind of soil they like? and whether they require much water? &c.—K. L.

2780.—**Onion Maggot.**—I want to sow a small Onion bed. How am I to keep clear of maggot in the early part of the year? Some of your readers strongly advise the use of salt, to be used about half-a pound to the square yard, and the same quantity to be repeated after an interval of some time. I acted on the advice given, and yet the maggot has destroyed a lot of mine, and still is destroying them. What am I to do?—ROBERT LAMBERT.

2781.—**Leeks not Growing.**—I have some Leeks growing with which I have been trying to do my best, but very few of them seem to grow erect or to thicken as I should like to see them; but instead of growing erect and thick they are only small, and the leaves lying perhaps, from some of them at least, 18 in. upon the soil. The Leeks are a first-class kind, so the fault must be with me.—R. L.

2782.—**Caterpillars in Cabbages.**—My Cabbages and Savoys are all being eaten away by caterpillars; the whole of the plants are completely wrecked. My time being greatly taken up, I cannot give them all the attention they need, but I spend a certain amount of time each day to look for them, and I kill all I catch, but they do not seem to diminish in the least. Is there anything I can put on the Cabbages and Savoys to destroy the caterpillars?—G. H. MORTIMER.

2783.—**Caterpillars on Gooseberry and Currant Bushes.**—What moth or butterfly lays the eggs that produce the plague of the present and last season? My garden is swarming with a large brown moth having orange underwings. Is it this insect that does the mischief? I have had three distinct hatches of the caterpillars. The last one is now coming out of the eggs. It is hopeless to try in a large garden to exterminate them, as fresh eggs are constantly being laid.—RUBY.

2784.—**Growing Lilies.**—I saw the other day an account of Lilies. Would some one kindly give an article on their culture, soil, and times of planting?—A WORKING MAN.

2785.—**Lily of the Nile not Flowering.**—I got a Lily of the Nile (Calla æthiopica) three years ago; I cannot manage to get a flower on it. I potted it in a 7-in. pot filled with fresh soil, also leaf-mould and a sprinkling of sand, in March last; all the length it has got is four leaves. I water it well and grow inside a window. What should be done?—A WORKING MAN.

2786.—**Planting Bulbs.**—I want to plant Tulips, Narcissus, Crocus, Leucojums, and Muscaris. When is the proper time of planting the above? and when do they require to be lifted? Do the Crocuses require to be lifted at all? I grow them in pots and boxes outside a window.—A WORKING MAN.

2787.—**Pansies Rotting Off.**—Can any one tell me what causes my Pansies to wither and die? The roots seem to be all rotted off close to the stem, but the gardener cannot explain what is the reason.—BOB.

2788.—**Nature Printing.**—Will some one give me a short sketch of the process of nature printing from leaves, Ferns, &c.?—W. A. L.

2789.—**Uses of Sewage in Gardens.**—I have a cesspool requiring to be emptied. What is the best mode of using the contents in a small garden having a shallow soil upon chalk?—H.

2790.—**Sowing Everlastings.**—Can any one tell me if it would answer to sow Helichrysum seed in autumn for the purpose of having early and strong flowering plants? if so, when should the seed be sown? and what protection would the young plants require through the winter?—AMATEUR.

2791.—**Columbines.**—Do these plants require any particular soil or treatment? I cannot succeed in growing them well in my garden.—H.

2792.—**Honeysuckle Dying.**—Last autumn I planted a Scarlet Trumpet Honeysuckle. It made two shoots this spring, and until a few weeks ago seemed to be doing well; since then one of the shoots have died and the other seems to be dying. Can any one suggest the cause, and if so the remedy? It is in a light and fairly good soil on a south wall.—J. J.

2793.—**Stove and Greenhouse Plants.**—Will some one give me the names of eight stove plants that are the best for supplying cut flowers in winter, and if to be planted out or grown in pots? Also best eight for same purpose suitable for intermediate or warm greenhouse, not to include Bouvardias or Primulas.—D. D.

2794.—**My Failures.**—Will someone give me some information on the following subjects? I have a quantity of Raspberries; they make excellent growth each year, but produce no fruit; the canes are very prickly. My Red Currants do not make any growth or produce scarcely any fruit. The autumn-sown Onions (about half of them) have rotted off as far as the earth has touched them; they have not been watered at all. The earth is in good heart and rather stiff.—WALTHAM.

2795.—**Greenhouse on East Aspect.**—If I place against the wall of a house (facing the east) a greenhouse, can I grow in it Peaches, Roses, or any other kind of fruit or flowers? Of course the greenhouse placed thus will receive the sun's rays only till about twelve o'clock noon.—XENOPHON.

2796.—**Plants for Frames in Winter.**—I have always grown Calceolarias successfully in a frame by simply protecting them a little in the severest part of the winter. Can any one inform me of other useful plants that can also be grown in the same way?—SUBSCRIBER.

2797.—**Araucaria imbricata Failing.**—I have a fine specimen of this tree about twenty-five years old which begins to lose some of its lower branches, while the tips of other branches are turning yellow. Is there anything to be done to stop the process of decay?—G. H. L.

2798.—**Flowers all the Year Round.**—As I am one of those who like to see flowers at all seasons of the year, and being anxious to make the most of a small piece of ground, I should feel obliged to any reader for a hint on what kinds of flowers for blooming out-of-doors in the late autumn may yet be obtained either by cultivation or by the purchase of inexpensive kinds. My present stock will, I suppose, cease flowering during September. A hint would also be acceptable on the best method of sowing annuals now for blooming in the spring?—RUSTICUS.

2799.—**To Keep Rain Water Pure.**—Can any correspondent kindly advise as to the best means of keeping rain water pure? We live in the country on the top of a hill where the air is pure, but the one drawback is scarcity of good spring water. To make up this deficiency we catch in large tubs all the rain water we can from the buildings, but find it all has more or less a disagreeable smell. Should the tops of the tubs be kept exposed to the air or covered over? and is there anything that could be put into the tubs to act as a drainer, and to purify the water? and what is recommended? We also have a house in the town, and find the rain water there much purer (so far as smells are concerned) than in the country, which surprises us. The tubs used are brandy or port wine casks of a large size.—C. G.

2800.—**Ants in Houses.**—Can any one inform me the best method of getting rid of these pests? I am informed the presence of ants is a sure sign of damp. Is this correct?—F. T. P.

2801.—**Grass Going Brown.**—My Grass has become within this last two weeks very bare in places and seems to be dying. I am not aware of anything having been thrown upon it. What can I do to restore it?

2802.—**Botanical Distinction of Fuchsias.**—I have read the remarks in GARDENING about Fuchsia coccinea, and I should be much obliged if correspondents would describe the botanical distinctions between F. coccinea, F. Riccartoni, F. gracilis, and F. Thompsoni, and any others that are similar? I have four kinds or more which are similar, but not identical. But though I can see distinctions between them I have no means of naming.—A. B. G.

2803.—**Garden Hammock.**—Would "A. T. L.," who writes on the above subject, June 12, or any other correspondent of GARDENING ILLUSTRATED, kindly give me and other readers a little information as to the construction of these hammocks. I have made one of thin twine netted 2-in. mesh, 6 ft. square, and continued the ends out 18 in. with strings, and whipped them over a small ring with a groove round the outside, so that the strings all pass round the ring, and the rope to suspend the hammock runs through the centre, but do all I will to it I cannot get it to hang right, for as soon as any one gets into it, it twists so much that you must be very careful, or will find yourself thrown to the ground.—HAMACA.

2804.—**Caterpillars on Lime Trees.**—Can any readers inform me what can be done to destroy small green caterpillars, which have eaten the leaves of young Elm, Sycamore, and Lime trees in an avenue?—E. J. W.

2805.—**Dandelions on Lawns.**—We have lately taken a house which had been void for some years, and the lawn seems composed of Dandelions. Can any one give me an easier method of getting rid of them than the apparently endless way of digging them up? Would constant rolling and cutting eradicate them in time?—CONSTANT READER.

2806.—**Blooms Dropping from Scarlet Runners.**—What is the cause of all the blossoms of my Scarlet Runners falling off without leaving the Bean? The ground has been well manured, and the plants seem very healthy and apparently free from insects, and the stems when broken appear very juicy. There are few birds in the neighbourhood, and there are no slugs in my garden.—BRAYBOURNE.

2807.—**Copying Machine.**—I am unable to get Crawshaw's Dye. I have got a sixpenny bottle of Judson's Violet Dye. Ought it to be diluted with water? If so, with what quantity?—A TEACHABLE READER.

2808.—**Freesia refracta alba.**—Last autumn I bought a dozen bulbs of this, and potted and treated them the same as I would Lilium bulbs not having shown any signs of growth. I have just turned them out of the pot, and find that every bulb has produced another bulb as large as itself. Can any one tell me how to treat this plant through the medium of GARDENING ILLUSTRATED?—WASHINGTON.

AQUARIA.

Aquarium Difficulties.—I have read "Newt's" communication with interest, especially his method of making an aquarium. He asks for the opinion of fellow-readers with reference to the loss of his minnows' fins and tails. It is highly improbable that his tadpoles are the culprits, for they are herbivorous, and subsist upon the minute algæ, so plentiful in ponds and aquaria; nor do I think the tadpoles' masticatory apparatus sufficiently sharp or strong to bite off a fish's tale or fin. I should sooner be prepared to hear that the minnows had bitten off the caudal appendages of the tadpoles. But is "Newt" certain no other enemy has been introduced to his aquarium? Probably the minnows have been fighting among themselves and thus got damaged. "Newt" also complains of his want of success in stickleback keeping. We have always believed that sticklebacks are the hardiest and most interesting fish to keep in an aquarium, and out of about fifty brought home about six months ago two have died. The remainder are still as healthy and active as ever, and that in water supplied by the Southwark and Vauxhall Company, which has not the reputation of being absolutely pure. The question suggests itself, "How were these thirty sticklebacks of 'Newt's' brought to London?" If they were crowded together in a small vessel without sufficient vegetation, or were much shaken up by railway journey, or the vessel exposed to the sun, either of these circumstances would be sufficient to ensure their death soon after arriving in a strange water. I would, however, advise "Newt" not to be disheartened, but to get a fresh supply of these interesting creatures, with which I hope he will have more success.—E. STEP.

Food for Fish.—What is the best kind of food for gold fish in a globe?—H. S.

Water Plants and Fish.—I have a small tank in a rockery in the conservatory. Will any one tell me the best kinds of plants to grow in it to keep up a display as long as possible? Also what kinds of fish can I put in the tank besides gold fish, minnows, and snails?

HOME PETS.

Canary with Swollen Feet.—My canary is suffering from soreness and irritation of its feet; the skin is scaly and swollen and red at the joints. I bathe and put olive oil on them every morning, but they appear to be getting worse. Can any one suggest a remedy?—N.

Canaries Unhealthy.—I have kept canaries for twenty years, and I believe that all the effects mentioned may be produced by allowing them to be in a thorough draught. The parents being sickly were not equal to the task of feeding the young ones.—A. H. L.

Swelling on Bullfinches' Feet.—The horny lumps may be only dirt collected through the bird not washing, and maybe the cage has not been kept scrupulously clean, or it may be a disease which birds suffer from occasionally. If the former, which I hope it is, the best way is to gently catch the birds and immerse its feet in warm water, and then endeavour to take the lumps off, which, if they are only dirt, will come off easily.—A. d'A.

Bullfinch Not Washing.—I keep a canary and thrush; when they will not wash I take a small waterpot with a fine rose, fill it, and pour the water over them as they are in the cage; also I take the birds out and well wash their feet, as cage birds suffer with disease in the feet if not kept clean; also I cut their claws if they are long.—H. C., *Dartford*.

2777.—**Rabbits.**—Can any one tell me of a really good book on rabbits?—HOME PETS.

THE HOUSEHOLD.

Preserving Carrots.—Will some one kindly give me a simple receipt for preserving young Carrots in ginger syrup? I have seen them often, but do not know how to preserve them.—HOUSELEEK.

Sago and Fruit Pudding.—Weigh ¼ lb. of sago or tapioca, put in a pie dish that will hold 3 pints, cover the sago with 1½ pint of cold water, and put in a moderate oven until it looks clear, and has absorbed the moisture. Have ready prepared about 1 lb. of fruit, such as Rhubarb, cut up small, Apples pared, cored, and quartered, Gooseberries, Raspberries, &c., picked from stalks. Stir them into the swollen sago, and add about 3 oz. of brown sugar. Put in the oven to bake for about one hour. A little cream or milk poured on as sauce makes it most delicious. The sago must be well stirred to break any lumps there may be. It may be eaten hot, or if poured into a wet mould can be turned out and eaten cold.—J. W.

A Gentleman of Colour on Brown Bread.—Seems to me dat most people hab only half a loaf when Nature meant dem to have a whole one. Dey hab de white half, dat is nearly all starch, and all de odder part is giben to de rabbits and pigs. My heart is full of sorrowment when I see a poor woman go into a shop and put down good money for bad bread. If bread had always been white, it would nebber hab been called a staff, but a broken stick. Dare are thirteen minerals in de human body, and dey are all packed away in dat lubly little loaf called a grain ob Wheat. It costs de farmer many pounds for manures of different kinds dat de Wheat may be perfec; and arter money, hard work, and Nature hab done all dair work in the most perfec manner, de miller takes dis bootiful golden grain all to pieces, unpacks all the marv'lous 'gredients wid which it am stored, and actu'lly has de wickedness to take some ob it away and trow it to de pigs and rabbits, and other poor relations, when Nature sent it all for us.—*Evans' Journal*. [True as this may be, all interested in the matter should make a clear distinction between the filthy, and injurious, and ill-tasting brown bread made by many bakers in towns and the best and purest article. The sweetest and best bread in the world is that made on the griddle in Irish and Scoth farmhouses, without yeast, and raised by means of sour milk or good butter-milk and soda.—EDITOR.]

GARDENING
ILLUSTRATED.

VOL. II.—No 76. *SATURDAY, AUGUST* 21, 1880. PRICE ONE PENNY. WITH COLOURED PLATE.

HARE'S-FOOT FERNS.

MOST people are acquainted with the Hare's-foot Fern. It derives its name from the brown rhizomes or surface roots which bear a resemblance, both in form and colour, to the foot of a hare. There are many species of this Fern suitable for greenhouse culture, and also some that succeed best in a temperature higher than that of an ordinary greenhouse. The Davallias or Hare's-foot Ferns make excellent basket plants, and they are also suitable for growing on rockwork, their creeping rhizomes clinging to moist stones, and growing rapidly in a moist and shady situation, and they are also well adapted for culture in pans, as will be seen by a glance at our illustration of Davallia Mariesi, which represents a very elegant evergreen Japanese Fern sent to Messrs. Veitch and Son, of Chelsea, by their collector, Mr. Maries, after whom it is named. It has a creeping rhizome, about ¼ in. thick, covered with ash-brown scales. As a basket Fern for the conservatory and greenhouse it is one of the best. Its flexuose rhizome spreads freely in all directions, and its numerous fronds present an enduring mass of verdure. A first class certificate was awarded it by the Royal Horticultural Society last year, and the Royal Botanic Society also gave it a certificate of merit—a distinction which it well deserves. Among the older kinds there is Davallia canariensis, which grows well in any ordinary greenhouse, and yields abundance of bright green triangular-shaped fronds (leaves), which are well adapted for surrounding bouquets or vases of flowers. D. aculeata is a kind which may be used for covering damp walls or pillars. It climbs rapidly, and supports itself by clinging to the moist surface. D. elegans is also a charming kind, growing 2 ft. or more in height, and producing rich dark green shining fronds. D. pentaphylla is a dwarf kind which will thrive in a Fern case. The best soil for these Ferns is fibrous peat or light turfy loam, with a liberal quantity of well-decomposed leaf-mould and sand added. The best time to repot is in February or March, just as the plants begin to make new growth, and they may also be again potted in August, when large specimens are needed.

JAPAN HARE'S-FOOT FERN DAVALLIA MARIESII.

PTERIS SERRULATA.

THE common form of this plant has been cultivated in our gardens for more than a century. Of the crested varieties to be met with in gardens about a score have been found deserving of varietal names, some of the most distinct of which are here given :—

P. serrulata cristata.—This simply-crested form is a pleasing plant, especially when young, when its pinnæ seem to all radiate from a point ; it neither attains the size nor becomes so pendulous as the normal form, but this character adapts it for growing in small Fern cases, where the nor-

mal form, by its rapid growth, is unfitted on account of the length of its pinnæ.

P. serrulata angustata.—Of the dwarf forms this is the most elegant. Its pinnæ are very slender, not more than half the width of those of the preceding; the margins are very regularly toothed, and the points terminate in a digitate crest, with winged segments. Like the foregoing, it seems best suited for furnishing Fern cases.

P. serrulata polydactyla.—This is a form with distinctly forked pinnæ, the divisions of which are again cleft near the extremities, and the final divisions terminate in a broad, flat crest.

P. serrulata pellucida.—This variety is a recent addition to the group, and is remarkable for its much-branched crests and pellucid texture, which give it the appearance of some of the green sea-weeds.

P. serrulata maxima cristata.—The uncrested form of this plant grows more erect from its earliest state, is of a darker green, and altogether more robust than the type. The crested variety includes numerous forms, which, though agreeing in dimensions, vary extremely in breadth of the pinnæ and division of the crest.

VEGETABLES.

POTATOES.

A GREAT deal is at the present time being written about the Potato, because this is the season of its harvest, and the disease is appearing largely in the tops, although so far not in the tubers to any considerable extent. I trust no amateur growers will be in too much hurry to lift their crops until they have had every chance to mature and ripen in the soil; still farther, that when they do lift they will wait until the soil is fairly dry, because the cleaner or freer from soil the tubers come out the better will they keep when stored. Pulling off the haulm, if done carefully, is not attended with risk, but it is not at all certain that much is gained thereby; whilst if some hot days were to intervene, the leaves that are affected and the fungus would soon be roasted up. Cutting off the tops is a dangerous proceeding, because the cut stems continued for several days to emit sap over the soil, and is productive of much harm. I must say that all these experiments have never yet repaid for the labour involved. If those who plant Potatoes would but give them more space between the rows much less mischief would happen, because, first, there could be more soil added in the earthing-up, a most important matter, leaving the ridges fully exposed to the sun and air. I am now lifting grand, clean crops of many kinds from rows 3 ft. apart, and well earthed up. The samples are large and clean, rows of 50 ft. giving from 60 lb. to 70 lb. of fine tubers. Although the soil is naturally holding, yet in spite of so much rain, it is about the tubers quite dry and free, and this and the cleanness of the Potato I chiefly attribute to the fact that before planting in the spring I buried in the furrows a good layer of fresh, sweet, long, stable manure, and this has acted at once as drainage, and as a stimulus. No pleasure in gardening could be greater than that of lifting such beautiful crops as I am now doing, and that too of some seventy kinds.

The Potato Crop.—This is this season the finest in the locality that has been lifted for many years. Complaints as to the disease are few so far, but the fungus has made itself more evident in the haulm during the past few warm nights than through all the rains and thunderstorms. Although we have now occasional rains, yet I do not think there is danger of any large amount of moisture falling for some time, and rather hope for the fine autumn. Should this hope be realised, the tubers will be far better in the ground till well ripened than out of it. Exposure to the air before the skins are well set is fraught with danger and deterioration to the tubers. The market growers have mostly cleared out their stock of Ashleafs, and are now hard into the Regents, which are turning out a fine clean crop. The simple fact that the Regent is so good and so healthy speaks volumes for the condition of the Potato crop. Champions are not largely grown here, the growers dislike them, but Magnum Bonum is a great favourite, and is largely grown. This kind will give enormous crops presently, growing chiefly for seed purposes. I have here a large number of kinds, but all are so good, that special selection would be almost invidious. The American kinds come out fine this year, and quite free from disease. Early Ohio, Early Rose, Beauty of Hebron, Mr. Bresee, Manhattan, Snowflake, Triumph, Trophy, Climax, American Purple Kindey, all give grand crops, but of course, although good in their way, do not equal our best home kinds in table quality. Of English kinds the Early Lemon Ashleaf, Early Market, Bedfont Prolific, Porter's Excelsior, Lye's Wiltshire, Snowflake, International, Grampian, Rector of Woodstock, White Emperor, Woodstock Kidney, Schoolmaster, King of Potatoes, Feltham White Round, and Vicar of Laleham, so far as lifted, are all cropping splendidly, and so far are healthy. If my own crops correctly typify the general condition of the Potatoes in other places, there ought to be this year at the Crystal Palace the finest show of tubers that has ever been seen.

Early Ohio Potato.—This is the earliest of all the American Rose type of Potatoes, has of all the shortest haulm, resembles Beauty of Hebron in colour of skin, but is rounder and turns out a much more even table sample. I strongly recommend this kind because I find it in table quality quite superior to all other Americans; indeed, even now when boiled it becomes as floury as a Regent and quite as good. Its short top admits of its being grown in rows at 24 in. apart, and on a warm border will, I am sure, beat all the Ashleaf Kidneys in earliness. It is not a new American kind, but has only recently been introduced into commerce here.—A. D.

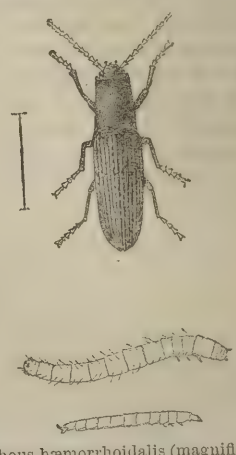
GARDEN DESTROYERS.

WIREWORMS.

(ATHOUS HÆMORRHOIDALIS AND AGRIOTES LINEATUS.)

WIREWORMS are generally most abundant in newly-made gardens, particularly if the ground has been previously pasture land. When they are present in great numbers they can only be got rid of by much trouble and labour. There have been many means suggested for keeping this insect in check, but few are of much use unless the ground be well cultivated, and care taken to destroy every one which may be found. No portion of a garden should be allowed to remain undisturbed and covered with weeds for any length of time, for such places form regular hotbeds for the propagation of these and many other insects. Most birds, particularly rooks, starlings, blackbirds, thrushes, pheasants, and partridges, are very fond of wireworms, and if the ground be kept properly worked, so that they can get at them, they destroy immense numbers. Moles also are their deadly foes, and certain carnivorous beetles belonging to the family Carabidæ kill quantities of them. Slices of Potatoes or, in default of these, slices of Beetroot, Turnip, Carrot, &c., or pieces of Lettuce or Rape-cake have been found very useful as baits when buried about 1 in. below the surface near any plants which have been, or are likely to be, attacked by these grubs. Each bait should have a small stick stuck into it, so that it can be removed and examined; this should be done every morning, and the wireworms which will be found boring into the bait destroyed. Some recommend merely laying these baits on the ground as being more efficacious than burying them, a plan which is certainly simpler, and might be tried as well as the other. Some plant Daisies, the roots of which the wireworms are particularly fond of, to attract them from any plants they wish to preserve. Gas-lime, and a mixture of lime and fresh soot, well incorporated with the soil, are very effectual in keeping them in check. Common salt strewn over the ground and well dug in (about 6 cwt. to the acre) is also much recommended. Rolling the ground is of little or no use, as the wireworm is so tough, and generally so far below the surface, as to be unhurt by any ordinary rolling, and the ground is made harder, and consequently birds have more difficulty in getting at them. Fortunately, the wireworms are not free from parasites; a very small ichneumon fly finds them out and deposits its eggs within their bodies. They are also infested by a minute intestinal worm. Both these parasites no doubt assist in checking their increase. The beetles should always be destroyed whenever they can be found. They are at times attacked by two species of minute ticks, but it is very questionable if their numbers are reduced by these parasites.

A very successful cultivator of Picotees and Carnations tells me that he always had the earth in which he grew his plants carefully



1.—Athous hæmorrhoidalis (magnified).
2.—Wireworm (magnified and natural size).

looked over twice on the potting bench to be quite sure there were no wireworms amongst it; and even then he placed a piece of Carrot in each pot, which was examined every morning, and the plants were not considered safe until the Carrot had not been touched by wireworms for a few days. In 1874, a piece of land near Worthing, which had not been cultivated for two or three years, during which time it had been lying waste, was made into a flower garden;

3.—Agriotes lineatus (magnified).
A.—Side view of thorax of ditto.

during the first year nearly all kinds of herbaceous plants suffered much from the attacks of the wireworm, particularly Carnations, Pansies, Daisies, Polyanthuses, and Sweet Williams. Whenever a plant was found to be drooping, it was lifted and a careful search made for the worms, when sometimes five or six would be found on one plant. The second year the damage, though considerable, was much less, the same plan being pursued. The third year the number of wireworms was so much diminished, that no particular care was taken to exterminate them, but every one met with was destroyed, as well as any of the beetles. The garden is now nearly free from them.

Wireworms appear to be almost omnivorous, as far as the produce of kitchen gardens is concerned, and the flower garden fares little better. Such plants as Irises, Ranunculuses, Anemones, Lobelias, Dahlias, Stocks, and the plants already mentioned, are amongst those particularly liable to be attacked. Young trees in nursery gardens often suffer much from these insects. The Ela-

teridæ are a tolerably large family, containing nearly sixty British species. The beetles are all long, narrow, and oval, with very long thoraxes; they are usually of a dull brown or yellow colour, but some are more gaily coloured; they are mostly very active and fly well; if disturbed they generally fold up their legs and antennæ and feign death, and if on a flower fall to the ground. Their legs are so short, that if one chances to fall on its back it could not right itself were it not for the following peculiarities in its structure: The thorax is furnished beneath with a small spine (fig. 3A), and which fits into a cavity in the breast when the insect lowers its head and thorax. If the beetle falls, or is laid on its back, it raises its head and thorax, which forces the spine into the cavity; then forcibly trying to straighten itself again, the spine flies out with an audible click, and the insect is raised several inches into the air and generally falls on its feet; if it does not, it makes another jump. The beetles are quite harmless, and may generally be found on flowers, particularly umbelliferous ones, stems of Grass, under stones, &c., during the spring and summer. The females are provided with longish ovipositors, which they can protrude or retract at pleasure; with these they deposit their eggs, which are very small, oval, and whitish, during the summer below the surface of the ground, near or on the roots of some plant. The number of species of which the wireworms are destructive is not exactly known. A very large majority live in decaying and decayed wood, but probably ten or twelve, or perhaps more, are injurious to garden and farm crops. The grubs of the following species, however, are very destructive and very common, particularly those of the first two—Athous hæmorrhoidalis, Agriotes lineatus, A. sputator, A. obscurus. The wireworms are all long, narrow, smooth grubs, of a yellowish colour, and are very tough and horny, resembling very much the common meal worm in general appearance, and they are tolerably active. They are very long lived and grow very slowly, for they do not attain their full size for five years; at the end of that time those of the largest species are about ¾ in. or rather more in length. When full grown they descend deeper into the earth, and form small, oval cells in which they undergo their change to the chrysalis state.

Athous hæmorrhoidalis is about ½ in. long; the head is black, with shining eyes of the same colour, and is furnished with a pair of dark, reddish-brown antennæ, consisting of twelve joints. The thorax is bluish-black in colour, and covered with very minute pale hairs, which are scarcely visible to the naked eye; it is long and narrow, with the sides nearly parallel, and terminating in a spine at each angle of the base; the wing cases are rather wider than the thorax, and are long and narrow; they are not quite as long again as the head and thorax together; the sides are nearly parallel, but gradually converge to a point; they are of a dark reddish-brown colour, covered with fine pale hairs; they are striated with several finely punctured longitudinal lines; the legs are short with long feet, and of a chestnut-brown colour.

Agriotes lineatus is about ⅝ in. long, and is considerably stouter in proportion than the foregoing species; the head is small and blackish; the antennæ are reddish-brown, and consist of twelve joints; the thorax is dark brownish-black, shaded at the edges into chestnut; it is nearly as wide as it is long, and very convex; both sides terminate at the base in a spine; the wing cases are long, oval, and convex, with somewhat parallel sides; they are striated longitudinally with several punctured lines, the spaces between the lines being alternately brownish-black and chestnut; the entire insect is covered with minute pale hairs.

The wireworms of different species are very similar in appearance, but they can be distinguished by the last joint of the body, which varies in form; the distinctions are, however, not worth mentioning here. They are all long, narrow grubs, horny and very convex above. Their bodies are composed of twelve smooth, yellowish joints; the three first each bear a pair of short legs; the last is furnished below with a retractile tubercle, which serves the purpose of a seventh leg; this last joint is generally roundish and flat at the top, and usually more or less toothed at the edge, but varying in this respect according to the species. The first joint of the body is much larger than the three following ones. The head is somewhat darker than the rest of the grub; its mouth is furnished with minute feelers and a pair of strong, toothed, reddish-brown jaws; there are a few scattered hairs on the body. The chrysalis is nearly as long as the perfect insect and of the same form, all the limbs of which are distinctly visible through the semi-transparent skin in which they are wrapped. G. S. S.

FRUIT.

STRAWBERRY CULTURE.

A PAMPHLET, consisting of some fifteen pages, on "How to Grow Strawberries with Success," by Mr. W. Lovel, Weaverthorpe, York, has recently reached us. Amongst other useful advice contained in it we find the following on the

Preparation of the Soil.

"Before you build a house," says Mr. Lovel, "make sure that you have a good foundation; and before you plant Strawberries, mind and have the land in good order, deeply cultivated, well manured, and clear of weeds and slugs. Three months is not too long to be making preparation, but six months is better. A bare fallow from autumn to midsummer is a good preparation for Strawberry planting, but a better way is to grow a crop on the land during the spring months. What is the best crop to grow, so as to have the land in good condition and at liberty by the first or second week in July? There is no previous crop, in my opinion, so suitable as a Potato crop—I mean a well-cultivated early crop of Potatoes—to have the crop off the land by the middle of July, ready for taking up three weeks or a month before the general crop is ready, when they are worth from 2d. to 3d. per lb. in the market; worth, if a good crop, £50 to £60 per acre. In this district we have sharp frosts during the month of May (6° to 10°) nearly every season, and Potato tops are liable to be cut off if left unprotected. Now, although a slight frost in our valley will spoil the most promising crop, yet, with a little forethought and contrivance, they may be saved. For a crop of early Potatoes I plant the first week in April, or as soon after as the season will permit. Mona's Pride Ashtops are the sort I use, having had the sets spread out in a light, warm place two or three weeks previous to planting. In a month from planting the tops will be bursting through the soil, and I now commence operations with the hoe and fork, hoeing the land over, stirring the soil round each plant, and digging the intervals over with the fork. You must watch the weather closely, and if there be the least sign of frost pull a little of the loose soil over each Potato. You may protect them from frost in this way for a few days, but if the land be in good order, and the Potato sets properly sprouted before planting, they will grow themselves clear of the soil in a short time, and some other means of protection must be adopted. Rough straw bands, the rougher the better, placed over each row, and held up by short stakes, will protect the tops from a sharp frost. I have also found the bushy tops of the common Whin or Gorse to answer admirably in affording protection from frost to both vegetables and fruit trees. Cut into lengths of 18 in. to 24 in., and stuck in the ground on the north or east side of the plants, they will save the crop from harm during a sharp frost, and after they are done with in the garden they will come in useful to kindle the fires with in the house; but 'It is bristled with thorns, I confess,' therefore be furnished with a pair of stout gloves before attempting to handle them. I am a mighty advocate for thorough cultivation of the soil, therefore I never miss a favourable opportunity of working the land where the Potatoes are growing. The more you work the land the faster the Potatoes will grow. You become thoroughly interested in the work, and all sense of labour and trouble is annihilated—toil becomes a pleasure. The Potatoes are planted in rows 30 in. apart and from 9 in. to 10 in. between each set, and if you wish your crop to do well—to grow quality as well as quantity—do not crowd the plants together, but let them have plenty of air and sunshine. Hoe among the crop once a week during the period of early growth, and at the same time fork over the intervals. If this be done, two-thirds of the land gains all the advantages of a fallow, and by the time the Potatoes are ready for earthing-up the land is in as fine condition as possible, as mellow as meal; such a thing as a weed is never seen, and as for the slugs, they have all disappeared—died of hunger, or perhaps emigrated.

"Now this is the land to plant Strawberries on. As soon as the crop is off the land dig it over two spits deep—it will be all the better for the deep digging—subsoil it, though do not trench it; be careful about trenching, or perhaps you will get wrong. I have seen land that has been trenched made so barren by the operation that even weeds have refused to grow on it for a season. I never trench land before it has been subsoiled two or three seasons previously, for I have found from experience that bringing the raw and hungry subsoil to the surface and burying the top soil is a great mistake. Keep the top soil on the top, and dig the second or bottom spit over, letting it remain at the bottom. If the land has been well cultivated, there will be neither weeds nor slugs to trouble you, and it may be either planted at once or it may have a few weeks' rest. If the land be poor, do not be afraid to give it a good dressing of manure before planting—a barrowful to every row of thirty plants will not be too much. Neither animals nor plants do well if they are pinched for food, and Strawberries are no exception to the rule; in fact, they are in this respect somewhat like our Saxon forefathers, 'gross feeders.'

"I have spoken of Potatoes only as the crop to precede Strawberries, but I suppose it will not always be convenient to have them so. I know of no crop that will leave the land in such fine condition, therefore I give Potatoes the preference; and if any of my readers are anxious to make money fast, I feel quite certain that Potatoes and Strawberries are two of the best crops they can cultivate for this purpose. But Strawberries will grow after any crop if the land be properly prepared. A crop of early Cabbages or Peas will leave the land at liberty in good time. The objection, however, to these crops is, that the ground is left in a harsh, dry condition, and it will require some little time before it will be ready for planting on. Cabbages often harbour a host of slugs, and if proper precautions are not taken to clear the land from these troublesome customers they will make sad havoc of the ripe fruit. Extra care must be taken to get the land into a good state of cultivation. If it turn up harsh and clotty after the last crop, work at it till you get it into a mellow state, for it is a waste of time to plant either Strawberries or any other crop on unprepared soil. By all means give it a short summer fallow for four or five weeks, and if it be forked over two or three times it will be all the better for it, but it need not be dug two spits deep more than once. In some cases Strawberries have to be planted after Strawberries. This should be avoided as much as possible, but if there be no other situation available, no time should be lost in getting the old plants removed and the land dug over, and I should recommend a winter's fallow before replanting the bed, which may be worked over in spring and planted as soon as the weather is favourable. The great point to secure success is to have the land in a nice mealy state some time previous to planting.

"Having got the land into a fit state, the next important point is to secure some good plants, well grown, well rooted, and of good sorts, early, mid-season, and late croppers. I would recommend every amateur to cultivate at least one or two of each class. To grow a crop of fine large fruit the first season after planting, the runners should be rooted early in July. I always endeavour to get my first runners rooted during June, and as soon as they are nicely rooted I remove them to a piece of land specially prepared by thorough cultivation and plenty of manure, and plant them at a distance of 1 ft. apart each way, and here they remain until I have my land ready to receive them; it may be as early as July, or as late as October. I make a point of never planting before the land is in a good state of cultivation, and, further, I always contrive to remove them from the nursery-bed to their fruiting quarters during showery weather."

With this came a list of Strawberry plants grown for sale at Weaverthorpe, in which, in addition to all the best kinds usually cultivated, may be found the names of some that are new and well worth a trial.

Fruits Ripening in Orchard Houses.—Some people have an idea that stone fruits ripened on the open wall are better flavoured than those ripened in cool houses. Where such is the case it should be taken, I think, as a sign that something has been wrong in the management of the house. The chief sources of colour and flavour in stone fruits are light and air. Fruit trees that are growing in a dark, crowded, ill-ventilated house, and that during the last week of approaching maturity receive the same quantity of water that had been given previously, are not likely to produce fruit worth eating. But if the fruit be exposed to strong light, abundant ventilation insured, and less water given during the last ten days or so of their ripening, good-flavoured fruit will generally be obtained. Of course, I am assuming that the trees are healthy, the foliage in good condition, free from red spider and other insect pests, and only allowed to carry a reasonable crop.—H.

Fruit for Tarts.—Autumn-bearing Raspberries pay well for extra attention in the way of mulching, thinning out the weakly growths, and tying up the fruiting canes, if necessary to keep off the ground, or to improve the flavour of the berries by a freer exposure. If dry weather prevail, a good soaking of water will assist them. Red and White Currants on north walls will keep in a good condition through the autumn if well preserved from birds and wasps. Hexagon netting will do all this effectually, and at the same time admit a free circulation of air.

The Gooseberry Caterpillar.—Hand-picking is of but little avail in the case of this pest, as it increases in numbers with extraordinary rapidity. But one habit belonging to it gives us at once an efficient method of outflanking it. When full fed its habit is to penetrate the ground a short distance, and there spin a cocoon in which it undergoes its changes from the grub state to that of the fly, coming up as the perfect insect in about three weeks, the autumn larvæ remaining unchanged in the cocoons in the earth until the next spring. Taking advantage of this habit, the best remedy is to spread old sacks or rags thoroughly saturated with tar all over the actual ground covered by the tree. The tar does not injure the trees and catches the grubs as they fall with the intention of penetrating the ground to become pupæ, at the same time kills those already there and prevents their coming up out of the ground as the perfect insect. It is well to remember that for every two caterpillars allowed to escape a plentiful crop of new larvæ may be depended upon for the next season. Dusting the trees with sulphur is but of little avail, and the use of Hellebore, as has been recommended, is not only useless, as the caterpillars care nought for it, but it is highly dangerous, as I have known cases of poisoning arise from eating the fruit of the plants dusted with it. It is of no use destroying the old trees and planting new in their place; the new trees will be eaten quite as much unless the surface of the ground be also skimmed off to the depth of about 6 in. and burnt.—C. H. Griffith, in *Reading Mercury*.

Ripening the Wood of Fruit Trees.—The growth of fruit trees being now pretty well finished for the year, all laterals or breast-wood remaining should be removed, to allow the free access of air and sunshine to the main leaves on the spurs or branches from which a crop is expected next year. This will also at the same time improve the colour and flavour of the fruit now approaching maturity.—E. H.

Fruit Trees in Pots.—In October last, Mr. Hawkins, Ewenny Priory, Bridgend, Glamorganshire, sent us some photographs of his fruit trees in pots, of one of which the annexed illustration is a reproduction; and along with them the following account of the results of his mode of culture: "Wall fruit this summer has proved to be a complete failure in this part of South Wales. I think it my duty, therefore, to strongly recommend orchard houses and pot trees. We have now had nearly three years of failure out-of-doors with the wall fruits, and they have not paid for the labour bestowed on them. Owing to our situation being low, we get dreadful fogs and white frosts. My idea is that walls would pay better furnished with Plums and Pears. I have two orchard houses filled with trees in pots, and trees on the back wall in my lean-to house, which is slightly heated, but my span-roofed one is a cool house. In both houses I always get a good crop. The trees have only 3 ft. of ground each on which to stand, and yet the Peach and Nectarine trees this year in both houses averaged five dozen fruit each, large and small. On Plums and Cherries there were a great many more. Half-a-hundred trees can be grown in a medium-sized house. As the fruit from one tree is gathered, I place it out-of-doors and give the others a little more room. I have a Plum tree in a 15-in. pot which ripened 154 fine fruit. I have Pitmaston Duchess Pears weighing 1½ lb. each. Three Cherry trees carried seventy-six dozen. Pot trees in orchard houses are very profitable, and when in bloom they are a grand sight. The Peach called Prince of Wales has borne 89 very fine fruit, and is now in a 15-in. pot. The tree is twelve years old. Souvenir du Congrès, though a small tree, bore twenty Pears; it is in a 12-in pot; Durondeau,

Souvenir du Congrès Pear.

in a 13-in. pot, twenty-four Pears. Coe's Golden Drop Plum, in a 13-in. pot, has borne seven dozen very large fruit. These are not the only ones I have had like this; I have had more than half-a-hundred quite as good.

Potting Orchard House Trees in Pots.—Mr. Rivers says the soil about the roots should be "regularly pounded with a heavy pestle," and he attributes failure in most cases to loose potting. In potting such trees, if the soil be at all light or friable, it is certainly difficult to ram it so hard as to cripple their root action more than is desirable. All stone fruits at least exhibit marvellous power in penetrating hard soils. If the soil be healthy, the nearer it approaches the consistency of a soft burnt brick, the better they seem to like it. When the soil is rammed so very hard, however, in pot culture it is particularly needful to attend to watering, as the hardened mass of soil soon dries. In orchard house culture, firm potting, plunging, and liberal watering are points of more importance than anything else.—C.

Raspberry Arches.—I am glad to see that some one has tried with success what is the almost universal method of training Raspberries in the north. When four plants, forming the corners of a square, are tied two and two, so as to cross each other in the centre of the square, one set of canes always acts as a sort of buttress, and prevents the canes from being blown about with the wind most effectually. I have grown them in that fashion this year with most successful results. I unfortunately neglected to loosen the tyings before the buds began to shoot, so that the berries on the upper part of the canes were small, but every bud on the lower part of the canes started into growth, and produced a shoot from 18 in. to 2 ft. long laden with fruit; and the new canes are ripening so well, that one or two from each stool have already blossomed, and some are laden with berries which, in a green state, are already above the average size of ripe fruit.—J. D.

SOWING ANNUALS, PERENNIALS, &c.

Autumn-sown annuals should be sown in the open ground and, generally speaking, where they are to remain, the object being to get larger plants and a better display of bloom, as well as earlier flowering. The plan is usually adopted with spring-flowering annuals which are sufficiently hardy to stand the winter, and can so be brought into bloom and cleared away to make room for bedding plants. The best sorts for the purpose are—Virginian Stock, Nemophila insignis and its congeners, Silene pendula and its varieties, Collinsias, and Candytufts. No advantage would accrue from sowing these in the greenhouse now. There are several biennials and perennials, however, as well as many showy annuals, which could be grown with advantage with the help of a greenhouse, which could be slightly heated in the event of severe weather. Given the power of keeping the house at a temperature of about 50° in all weathers, the following would be a good procedure:—

Procure and sow now in pots or pans of light rich soil mixed with leaf-mould Campanula medium calycanthema, C. pyramidalis and C. pyramidalis alba, Aquilegia vulgaris (single and double), Delphiniums (mixed) and Delphinium nudicaule, Digitalis gloxinoides, Pansies (exhibition and Belgian), Primula cortusoides amœna, and perpetual Carnations and Picotees. None of these plants present any difficulties to the beginner. They must have plenty of air to prevent them getting drawn and weakly and moderate watering. As soon as the plants are large enough to handle they should be pricked off into separate pots. Those named before Pansies are large plants and will require large pots. The Campanulas and Aquilegias make good pot plants, and may serve to teach a beginner how to manage those. The Pansies will bloom before spring, and the best only need be kept. The Carnations and Picotees may either be retained as greenhouse plants or planted in the open ground. In the last week of February sow a pot of Hunt's newest Sweet Williams, Calandrinia umbellata, and Anagallis grandiflora in variety. In March sow Indian Pinks and Dianthus diadematus fl.-pl. After February, every day on which the outside temperature in the shade is over 40° all the air possible should be given, and all the plants except Calandrinia and Anagallis gradually accustomed to the outside air by the beginning of April; unless the weather is very cold and inclement, all the plants, except these two, should be in their blooming places in the open ground. In the middle of March sow Phlox Drummondi and Stocks, and Antirrhinums if desirable. Plant out the Stocks after hardening off as soon as large enough. In the last week of April or thereabouts, according to season, all the remaining seedlings may be hardened off and planted out. The heat may now be raised to 60°, and a good lot of Asters, Zinnia elegans (double), and Balsams sown; these require to be grown quickly in a steady temperature and planted out the instant the outside temperature is fully established at something like the same pitch. A selection of these will help to decorate the greenhouse as well, and many permanent greenhouse plants can be raised from seed during the first summer. Some experience of hardy plants should be gained before florists' flowers are attempted. Many of these have been nursed and coddled so long, that they have acquired a delicate consti-

tution, which unfits them for amateurs' culture. Calceolarias, Cinerarias, Chinese Primulas, and Cyclamens are easy to manage, however, and so are border and Alpine Auriculas, Primroses, and Polyanthuses; but these latter and their allies require more attention in the seed-pans than amateurs can usually give them, and can now be purchased as strong seedling plants, generally of better strains than the seeds can be bought of at a cheap rate. Bedding plants, properly so-called, such as Geraniums, Iresines, Alternantheras, &c., are not suitable for greenhouse culture in winter and open ground culture in summer; that class of plants require a house specially constructed for them, so that they can be kept as near the glass as they would be in an ordinary frame. Echeverias, however, can be kept anywhere if safe from frost and kept very dry. I kept some in an unheated greenhouse through a long winter by never giving them a drop of water except when the temperature was considerably above freezing point. By bedding-out time only about four leaves in the centre of each plant were alive, but they recovered and became strong plants in a fortnight when planted out. The silvery-leaved Centaureas are also very manageable if kept dry and airy. Amaranthus melancholicus ruber can be sown in heat in spring; it is an annual. Golden Pyrethrum can be treated in the same way; it is nearly hardy. The bedding Lobelias can also be raised from seed, but as that does not come very true it is better to buy plants. J. D.

Godetia Whitneyi.—This is, without doubt, one of the best annuals in cultivation. I have tried it now in nearly all kinds of soil that can be found in the neighbourhood of London, and cannot see any variation in its habit or behaviour. It only requires to be sown where it will get at least half the day's sunshine, and thinned out to 18 in. apart when it has made four leaves or so, and it will claim the admiration of every one who sees it in its flowering season.—J. D.

Sweet Williams.—I quite agree with "A. D.'s" remarks in GARDENING about the character of the Sweet William, and its suitability as a border plant When once a flower has been improved to the point reached in Hunt's strain, with smooth-edged petals, circular pips, and spherical trusses, it is a pity it should be allowed to run back to unimproved forms, for the culture of these by anyone tends to prevent seed of improved varieties being saved in any neighbouring gardens. Many years ago Mr. Glenny recommended the Sweet William as a likely subject for improvement into a florist's flower, and indicated scarlet and black as the combination of colour to be aimed at; but the perfection attained with light flowers in Hunt's and similar strains would seem to indicate improvement to be most likely to be obtained in the lighter colours at present. There should not be much difficulty in getting good strains from seed, as the bees seem to avoid the flower. It is not too late to sow seed to flower in spring if the plants are not moved, but only thinned out. The characters to aim at are a circular flower, with no indentation where the petals meet, thick in petal, and all the petals marked alike, the colours meeting each other in clearly defined lines without any feathering or flushing into each other. The truss of flowers should be a ball, and all the flowers forming it should remain in perfection until the whole are opened. All flowers having the feathered edge of the natural flower should be destroyed. A batch of seedlings raised last year have behaved in a way which would seem to indicate the following culture as a good one to insure the rapid multiplication of any particular variety:—Sow in pots, and allow the seedlings to become a little drawn and lanky before planting out. Plant out in light loam, dressed only with a little leaf-mould or loam from rotted turves, planting the seedlings so that a few of the lower joints are under the surface of the soil. When the blooming stems are well above the foliage prick in a dressing of guano all round the plants, give plenty of water in dry weather, and a further slight dressing of guano just before the flowers begin to open. The effect of this treatment has been a vigorous lot of strong stocky shoots from the buried joints of the plant, all rooted and ready to plant out as soon as the bloom is over. Another lot of seedlings from the same pot, which were planted in the same way, but in a rich turfy loam, show no signs of blooming. The main stems which should rise for bloom creep along the ground, throwing up shoots suitable for cuttings from every joint, and a little sheaf of them from the tips of the main stems, so that each plant would now furnish over a hundred cuttings. If the planted out shoots taken off after the first bloom could be induced to behave in that way, six hundred or more plants of one variety could be bloomed the fourth year after sowing the seed.—J. D.

Snowy Phlox (P. nivalis).—Amongst the Phloxes are several distinct types which differ in habit and time of blooming, but they retain in a well-marked manner the general structural characters upon which the genus was established. Thus we have a group of dwarf, trailing plants, all essentially early spring bloomers and admirably adapted for the rock garden, and we have the tall autumn Phloxes which constitute one of the most effective types of plants belonging to the herbaceous border, and which have received such attention at the hands of hybridisers that in point of variation their name is legion. To the first of these groups the plant here illustrated belongs: it is called the Snowy Phlox (P. nivalis). It possesses procumbent habit of growth; the flowers are of snow-white purity. Its specific title has therefore a double significance, being alike expressive of the appearance which its flowers present, and of the locality which it affects—near the snow-line of the Rocky Mountains. Drained

Snowy Mountain Phlox (P. nivalis).

ordinary garden soil, with a good sunny exposure, constitute the necessary elements of success. Though perfectly hardy and unaffected by even extreme frosts, they cannot endure the damp atmosphere of mild winters, the result being large patches of decay, if not absolute death of the plants. None of these species seed freely, and their increase must be by means of cuttings or layers; the former require very careful manipulation, as they are liable to break off just above the node or joint to which the leaves are attached, thus completely neutralising the chances of success. A sharp knife and a careful hand will soon remove the two or three pairs of leaves with their included buds without damaging either the slender stem or joint; and these, if taken off in July, when the branches are just commencing to harden, and inserted in sandy soil in a frame where they can be shaded from full sunshine, and given the benefit of midnight dews by the removal of the lights, will soon root and become good flowering plants the following season. Where large patches are growing, the readiest mode of increase is sprinkling sandy soil over the entire plant and working the same gently amongst the branches with the hand. If this be done during the summer or early in autumn, the trailing branches will be found to have formed roots, and may be readily removed and planted elsewhere the following season. By this means well-established plants are formed at once; but where numbers are required, increase by means of cuttings is preferable.—J. C. N.

Stock Mauve Beauty.—This lovely Stock is very fine indeed this year, the double-flowered plants forming massive pyramids of bloom, and rich in perfume. It is one of the sweetest scented, as well as the most pleasing of all summer Stocks; 250 plants gave sixty singles only, all the rest being doubles. Seed was sown under glass in March, and the plants dibbled out into the open ground at the end of May.—A. D.

Œnothera Fraseri.—If any one were seeking a hardy summer-blooming plant to form a bed, I should certainly commend this Œnothera as the best and most continuous. The flowers are of a soft and pleasing yellow, and are freely produced for a very long time; in fact, nearly all through the summer. The growth is somewhat prostrate, and the shoots are drawn upwards by the sun and the blooms exposed freely. Now that the earlier growths are getting over a mass of shoots are coming up from the base of the plants, and all full of bloom. It would make an effective plant to margin a bed of shrubs, or a raised basket bed, or, indeed, would look well in any suitable spot.—A. D.

Two New Clarkias.—These two new varieties of Clarkia, named Hardy's Purple King and Salmon Queen, are now very showy with me. Purple King is of a rich purple colour with red anthers; Salmon Queen is of a fine glowing salmon-pink, deepening to magenta-rose before the flowers fade. Both varieties produce a large proportion of double flowers. They have only got one fault, which is that they do not carry their flowers in clusters at the tips of the shoots, but on short stalks at the axils of the leaves in the manner of Balsams. Their growth seems very much affected by the nature of the soil they are grown in. I have some growing in light sandy soil which are nice stocky plants 18 in. high, with flowers just touching each other, while others which are growing in a bed of turfy loam are 4 ft. high and 3 ft. across, with the leaves and flowers far apart. Their habit of growth and flowering makes them peculiarly suitable for the tops of sloping banks and other positions where they would be seen from a lower level than the plants are growing at, and also for pot plants for windows. The habit of the plant is exactly like that of Solanum capsicastrum (the Winter Cherry). The flowers are rather over 1¼ in. across.—J. D.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

Aug. 23.—Sowing Radishes in frames to keep them from birds; potting Stocks, Phloxes, Tropæolums, Nemophila, and Lobelia; potting up the Neapolitan Violets, taking them up with large balls; putting in cuttings of Hollyhocks and Achillea Clavenæ; layering White Chrysanthemums; planting Strawberry plants, viz., Keen's Seedling, Garibaldi, President, Eclipse, Dr. Hogg, Oscar, Sir J. Paxton, Elton Pine, and Hautbois; staking Mignonette; tying pot Calceolarias; tying up Lettuces; shifting Poinsettia cuttings into 4-in. pots; putting several Lilium lancifolium roseum under cover; putting Asters in pots under walls in shade; repotting a few Sikkim Rhododendrons and Azaleas; earthing-up and watering latest-planted Cauliflowers; digging land for August-sown Lettuces; clearing Pea land for young Strawberry plants; giving all Celery a little earth to keep down suckers; cleaning last August-sown Cabbage stumps to make sprouts for winter; giving Lilies a top-dressing of manure; getting in some of each sort of herb for drying.

Aug. 24.—Sowing Bath Cos and Stanstead Lettuces; potting Cyclamens, also double Tree Violets; putting seedling Cinerarias into flowering pots; put in cuttings of Coleus, Heliotrope, and Ageratum; laying Cerastium in Box edging for planting in spring; planting Cucumbers in pit to crop well in October; filling up the Cabbage and Endive where eaten off by grubs; shaking out and repotting Pelargoniums; putting autumn-sown Onions in the sun to dry; finishing nailing summer wood on all wall trees; tying up and earthing some Endive; taking up for seed Ashleaf Kidney Potatoes.

Aug. 25.—Putting in Carnation cuttings; planting Stocks on warm border; finishing nailing Peach trees and exposing the fruit to the sun; taking up Plaintains on lawns; washing Azaleas with Tobacco-water for thrips; getting up all Potatoes; putting manure in span-pit for winter Cucumber plants; clearing land for Strawberry plantation; making a Mushroom bed; picking off dead flowers in flower garden; tidying up flower beds.

Aug. 26.—Sowing Mustard and Cress, also Cucumbers, for fruiting in February; potting Iris, large-flowered sorts; cutting down double Pelargoniums and remaining Lilacs; putting in cuttings of Centaureas in single pots in cold frame; digging land for and planting August-sown Incomparable and Imperial Cabbage; tying up Yew trees; parting some Aralias; putting the Solanums under glass; getting all stand plants set thinner on ashes; putting last year's pot bulbs in baskets to dry; thinning autumn Carrots.

Aug. 27.—Potting Schizanthus; staking Heliotropes in pots; getting all Chrysanthemums tied as quickly as possible; shifting spring-struck Tree Carnations into 5-in. pots for flowering; putting Centaurea and also Lobelia

seedlings into open pit; putting the Strawberry plants in pots a little thinner; shifting late Cucumbers into 10-in. pots; gathering Keswick and Hawthornden Apples; getting autumn-sown Onions stored away; pulling the whole of the spring-sown Onions; finishing cutting Laurels.

Aug. 28.—Potting Guernsey and Belladonna Lilies, also Hollyhocks, Brompton Stocks, Pinks, and Carnations; putting in cuttings of Oxalis; planting a few Walcheran Cauliflowers, some July-sown Cabbage, and 1st of August-sown Bath Cos Lettuce; tying up Asters; repotting latest-sown Balsams; watering French Beans under wall; taking off young Strawberry plants; thinning last-sown Mignonette; cutting off straggling shoots from Briers and Roses.

Flower Garden.

Pansies.—Cuttings of these may be put in whenever it is convenient. The old plants will make a fine autumn display if the very old spent stems are cut out. All small, weak stems should also be pinched out and used for cuttings. Place a rich dressing of rotten manure and loam in equal portions evenly over the beds between the plants; then peg down the medium growths over the compost, and if the soil is rather dry give a good watering. The small, hair-like roots run into the dressing in a mass, causing the plants to make a corresponding growth above ground.

Chrysanthemums.—After the roots have got fairly hold of the soil in their flowering pots they should receive strong manure water every other time they are watered. They will bear it as strong as any plant in cultivation. The Mushroom-shaped style of training is the most in favour with those who grow them for exhibition, but it is unnatural and useless for general decorative purposes. Plants of the larger varieties, confined to from five shoots each, neatly tied to a stick, the head of the plant brought out to about twice or thrice the diameter of the pots they occupy, will be found the most useful, and this will give them ample room for the development of their foliage, which if they are well grown will be of the darkest green. As the shoots of the large kinds branch out in growth, they should be thinned to the number of flowers the plants are intended to carry, leaving one flower to each shoot. The plants will carry from six to eighteen, according to their strength. To those who have not tried this thinning process it may appear a great sacrifice in quantity; but either for cutting or for decoration on the plant, one good flower is worth three inferior ones, and flowers so treated will last fresh on the plant fully a third longer than others that have been insufficiently thinned. The Pompones also require thinning, but not so much as the large varieties, neither in the reduction of the number of shoots nor in the number of flowers each shoot will carry; these may be left from three to half-a-dozen to each terminal shoot.

Budded Roses.—Those that were budded the first should now be looked over and the ties slackened, otherwise, through the thickening of the shoots, the bark will be all but cut through so far that the shoots are liable to be broken off by the wind, in which case the labour bestowed will be lost, as well as the season's growth. Where the buds inserted have started into growth the shoots beyond the junction may be considerably shortened, so as to direct the current of growth to the development of the bud-shoot, yet too much of the stock shoots should not be cut away, or the operation will have a corresponding influence in checking the roots, a circumstance that by no means should occur. In the spring when the Roses are receiving the most attention, the suckers are usually removed, but it is quite as necessary to take them off now as it is earlier in the season, otherwise they will seriously interfere with the strength which the present season's growth should attain.

Soot Water for Roses.—It may be well to again allude to the necessity for the frequent use of this to Roses in pots. Worms have a particular liking for the soil in pots where rich manures are used; on this account there are no plants grown that suffer more from their attacks than Roses. The fact of their bearing strong stimulants admits of the soot water being applied somewhat stronger than would be safe to use for many plants. Before giving it it is well to let the plants get as dry as can be safely done without the foliage being injured; then give a thorough soaking, the effect of which is that generally in a few minutes the worms, especially the large red ones, make their appearance above the surface, when they can be removed.

Glasshouses.

Gloxinias and Achimenes. — The earliest-flowered will now want to go to rest. Beginners in the cultivation of these plants are frequently led to attach little importance to the gradual maturation of the bulbs when the flowering is over and the leaves begin to look shabby, allowing them to die off too quickly; it is through this cause more than any other that the roots are so often found decayed in spring, in place of being plump and ready to start into growth. When they show signs of wanting to go to rest, they should still be kept in a warm house, fully exposed to the sun and light, just giving as much water as will keep the leaves from flagging to any great extent. This treatment with plenty of air will induce rest. When the leaves and stems have thus gradually died down, the roots will be in good condition, and no difficulty will be experienced in preserving them through the winter if they are kept dry, and not allowed to get too cool.

Coleuses.—These may be grown up so quickly that it is never worth while wintering any but very small plants or cuttings of them, which should now be put in for that purpose. They will strike readily in any shady place in the greenhouse under bell-glasses or hand-lights, put on to keep the air from them for a few days, when they can either be potted off singly, or kept in their cutting pots on a light shelf till the turn of the year.

Bilbergias.—As flowering plants nothing can exceed the beauty of some of these, especially the variety called B. Moreliana, a kind which produces its blooms in the freest manner possible during March and April, a time when such brilliant colours are exceedingly valuable. Unlike most of the Bilbergias, the flower-spikes of B. Moreliana, instead of being very erect, droop gracefully over, hanging clear from the centre of the sucker producing them from 1 ft. to 1½ ft. in length, so that when the plant is elevated by being set on a bracket or inverted pot, or suspended in a basket, it produces a striking effect, as do also the long spikes of bloom when cut and placed in tall vases, so as to depend over their sides. Those who are not already in possession of this Bilbergia should not fail to add it to their collections, as it is a plant that is sure to give satisfaction. If obtained now the plants will most likely be in a fit state to receive a shift into a size larger pot, well drain the pots, and use rough lumpy peat and loam for the purpose, with just sufficient sand to keep it open and porous. None of the above-named plants care for much pot room; fresh sweet-oil and plenty of drainage being of more importance than a large quantity, which is more apt to become stagnant and sour, conditions under which they soon lose their roots, and, of course, get into bad health. When potted they must be grown freely on by keeping them in a moist atmosphere where they can have plenty of heat.

Caladiums.—The earliest started plants of these should now be permitted to go gradually to rest by only giving them water occasionally at the roots. It is the practice with some to keep these slightly growing through the winter, but it is not to be recommended, as they never start in the vigorous way which they do when dried off and allowed to go completely to rest.

Balsams.—Push on the last batch of these by closing early, after giving them a good syringing; and, in order to keep them dwarf and stocky, they should be kept thin and well up to the glass, so as to admit plenty of light amongst them. Such sportive plants as Balsams are sure to show great variety both in the colour, size, and quality of the flowers; and to keep up a high standard of excellence with these, it is necessary to make selections of the best and most distinct to be set away from the others for the purpose of bearing seed. If the flowers be so double as not to produce seed freely, remove a few of the inner petals, and fertilise the stigmas by hand, using a camel's-hair brush for the purpose.

Fruit.

Vines.—It cannot be too often reiterated that all Grapes intended to keep well throughout the winter should be fully ripe before the close of next month. Lady Downes, Gros Colman, Alicante, Mrs. Pince, and Muscats require a full two months from the date of beginning to colour to become fully ripe, and owing to the season being so backward, more than the usual amount of forcing will be necessary to attain this end by the time named. Whenever there is sunshine the houses should be closed up by 2 p.m., and night ventilation should be put on about 7 p.m., accompanied by artificial heat, in order to maintain a minimum temperature of 65°, or, if very late, 70°. If the borders are inside give them a thorough watering when the Grapes just begin to colour, and repeat the operation if necessary any time before the fruit is fully ripe. The rainfall has been excessive, and therefore in some soils and localities outside borders will need coverings to throw off the rain, but on light soils and naturally drained borders, such coverings need not be resorted to till the Grapes approach maturity, when they are necessary. In order to colour Gros Colman well, we find it requisite to let the lateral growths extend as much as possible, and to tie aside the foliage to admit full sunlight to the bunches. Grapes that are ripe should be kept as cool as possible, but apply fire-heat in cold damp weather in order to keep the atmosphere buoyant, or the condensed moisture settling on the berries will cause them to decay. Early Vines may now be partially pruned, *i.e.*, all the laterals may be cut off, and the longest side shoots shortened back, but the old foliage should be left intact and kept free from red spider by frequent syringings. If necessary the borders should now be renovated and surface-rooting encouraged by the addition of fresh material. Outside borders like those of late houses may now require protection from further supplies of moisture.

Melons.—The last batch of plants should now be well established, and to be certain of satisfactory fruiting not less than 75° as a minimum bottom-heat must be maintained, and top-heat according to the weather. On bright, sunny days the temperature may run up to 85° or even 90°, provided the walls and floors are kept sprinkled; in other respects treat them as recommended for early crops. Plants that are swelling off heavy crops water thoroughly with tepid manure water. Generally too little water is given at this stage, and consequently the foliage perishes and the fruit is flavourless. It is a mistake to suppose that starvation, by withholding water, adds flavour to the fruit. Sun, and lacking this, fire-heat and air, are the flavour-producers.

Newly-planted Strawberries must be attended to with water if the weather be dry, or they will suffer to an extent that will greatly interfere with their bearing capabilities the ensuing season. The same applies to Strawberries in pots. Those who cultivate Strawberries in pots may rest assured that a good deal of their success depends on the plants being plentifully supplied with water so long as they are making any growth. Place them in the full sun on slates or boards in a square as close as the pots will stand. By this means they will protect each other from the full force of the sun, which, coming in contact with their sides while at all powerful, is injurious to the roots of any plant grown in pots.

Vegetables.

Potatoes attacked by the disease should be forthwith dug up, and all that are in the least affected picked out, and the others, before being finally stored, should be spread out in a dry, airy shed for a few days, and again looked over, picking out any bad ones. The remainder should then be pitted, and kept as free as possible from atmospheric influences. Spring-sown Onions, Shallots, and Garlic will all of them now be ready to harvest. The bulbs should be pulled up and left on the ground for a few days to dry, and then moved to the store-room to be finally cleaned and stored in bad weather. The ground which they have occupied will be in good heart for the main crop of Cabbages for early spring use. It need not be dug, but simply cleared free of weeds. Drills should be drawn 2 ft. apart, and the plants dibbled in 1 ft. apart, to admit of alternate plants being drawn out for use whilst young, and before they injure each other. The planting of all other kinds of winter Greens should now be finished, with the exception of Coleworts, which may be planted all the year round. A last sowing of Turnips, Winter Spinach, and Lettuces should now be made, for even though the supply may seem

ample, it frequently happens that these last sowings stand the winter best, and certainly in the case of Spinach there is not that liability to run to seed that the earlier sowings possess. Thin out crops of these that were previously sown as soon as the seedlings can be handled, and keep the ground well stirred, particularly after dashing rains. The first-planted Celery will now require earthing up, but previously remove all suckers and small outside leaves, and tie up with bast in order to prevent the soil from getting into the centres of the plants. The general stock should not yet be earthed up, for when once earthing is begun growth is checked, so that, as a rule, it is best to allow the plants to get fully grown before earthing takes place, *i.e.*, if blanched Celery be not required at an early date, at least a month should be allowed for blanching. Where dry herbs are required for winter use, this is a good time for them ; Thyme, Sage, Marjoram, Mint, Basil, and Balm should all be tied in small bunches, and if hung up in any dry room or shed they will maintain their natural colour. If dried in the full sun the leaves go black, and fall off when removed to their winter quarters. Even where dry herbs are not in request the plants will be all the better if shortened back and freed from flower and seed stems. Keep the stems of Tomato plants thin, and the foliage that overshadows the fruit picked off. Ridge Cucumbers also require to be well trained out, and surplus fruit constantly picked off, and if the present sunny weather continues, a fresh mulching of soil will be necessary in order to keep them in full fruit. Vegetable Marrows also require to have the fruit removed as soon as it becomes usable, in order to prevent impoverishment of the plants, and this, coupled with a bountiful supply of water, is about all the attention which they will require. Peas, Broad Beans, and all other crops should be cleared away as soon as they have become exhausted, both for the sake of neatness and to prevent any unnecessary exhaustion of ground.

Cucumbers in frames should be stopped at every joint where they show fruit, a practice which tends to prevent their getting so much crowded with superabundant shoots, as they otherwise would be ; but even under this treatment they will get too full of growth unless the knife is freely used from time to time in removing all that is not required. Where Cucumbers are wanted as late in the season as they can be had, and where there are no means of growing them, except in ordinary garden frames, they should be assisted with manure water regularly after they have been some time in bearing, and, above all, continually syringed, getting to every part of the leaf-surface, so as to keep them free from insects, without which all other attention will be unavailing. Where there are houses or pits in which to grow Melons and Cucumbers, the above directions are equally applicable.

Improving Lawns.—It would be a great boon to the possessors of small gardens if seedsmen would make up small separate packets of seed of the finer lawn Grasses and Clovers. The lawns of suburban houses are too often laid by jobbing gardeners with turf of one or two years' growth cut from the neighbouring building land, and composed almost wholly of weeds and coarse Grasses unsuitable for the purpose. It requires years of constant attention and cutting before such turf can become anything but an apology for a lawn. If small separate packets of Lolium perenne tenue, Poa nemoralis, and Trifolium repens were readily obtainable, Daisies, Buttercups, Dandelions, and tufts of coarse Grass could be pulled up, and a few seeds of these substituted, and the lawn gradually improved. At present there is nothing for it but cutting and rolling, and occasional top sprinkling of earth and guano mixed. A very thin sprinkling of the dust of old mortar and plaster will also do good. The benefit of rolling may be seen in country lanes, where plenty of seeds of weeds and coarse Grasses are always flying about, yet little patches of turf may be found in front of cottages, round walls, by the sides of footpaths and roads, and anywhere it is liable to be frequently trodden on, consisting wholly of the very finest Grasses and Clover, without a sign of a weed or coarse Grass. I know many such patches, on which the seeds of coarse Grasses are at present raining continually, yet they never seem to spring up. Turf cut from crude clay is the worst of all. I remember a lawn laid with such turf which remained as bad six years after it was laid as it was the first day ; 2 in. or so of the clay had been unavoidably laid with the roots of the turf, and although the soil was light and dry underneath, the clay became caked and puddled amongst the roots of the Grass with the rolling, so that no fresh seeds could be made to germinate, and nothing but coarse Grasses, Buttercups, and Dandelions, which had strength enough to push through the hard surface, would grow.—J. D.

GLASSHOUSES & FRAMES.

Conservatories and their Contents.—The heat that has prevailed of late has necessitated an increased quantity of air being given to keep down the temperature of these structures to as low a limit as possible, and the effect of this is, that the borders in which creepers and other plants are growing have been robbed of their moisture. This may not be apparent if only an examination of the surface be made, as that frequently misleads from the constant damping which it undergoes in order to keep the air of the house sufficiently humid. It should be borne in mind that the demand made on the roots of plants at such a time is at least twice as great as it is when the weather is still and cool, or the sky dull and overcast. With the air in constant motion, as it necessarily is when all the means of ventilation possible have to be made use of, evaporation goes on at an extremely rapid rate through the pores of the leaves, and the whole of this, as a matter of course, is taken out of the borders, but much deeper than can again be made good by mere surface-waterings ; they should have a thorough soaking by going over them two or three times, leaving an interval of a day or so between each application, by which means the dry soil beneath will have time to swell and fill up the interstices, thus intercepting the water in its rapid passage through to the drainage without wetting the whole, an occurrence that frequently takes place when borders get into a dry, shrunken state. Among choice climbers Lapagerias, both red and white, are fast coming into bloom, and will be most attractive for some two or three months to come. They delight in having plenty of moisture at the roots and a rough porous peaty soil to grow in. With this resting on a well-drained bottom, water may now be given them at least once a week till they have completed their growth and ceased flowering, when less frequent applications will suffice. Where an increase of stock is desired, layering is the most expeditious way of obtaining it, an operation that may be carried out as successfully now as at any other season. Select a strong healthy shoot for this purpose, and remove the soil to a depth of 3 in. or 4 in., so as to form a channel in which to lay and peg down the branch, after which just bury it with sand and then cover up with rough lumps of peat and loam. If this be kept constantly moist, roots will be emitted within a year or so, when the layer may be severed and removed. Passifloras, Cobœas, Tacsonias, and other quick-growing climbers of a similar character should be kept regularly thinned out, so as to admit plenty of light and air to the plants beneath them. Most of the Tacsonias are subject to white scale, which, if not kept down now, will soon spread over the leaves and entail much future labour in clearing the plants from it. It first makes its appearance on the main stems and branches, from which it is easily dislodged by using any of the insecticides, which should be put on with a tolerably stiff brush. The utmost watchfulness must now be exercised in regard to Camellias, in order to see that they do not at any time suffer from want of water at the root, as when that happens the buds receive such a check as to cause them to fall off in the autumn just at the time when they should begin their final swelling. Weak liquid manure may now be given occasionally, especially to such as are confined to small pots, or have but a limited quantity of soil in which to grow. Clarified soot-water is perhaps the safest and best of all stimulants for Camellias ; it imparts a rich dark hue to their foliage. Those that make a satisfactory growth invariably show more flower-buds than they are capable of carrying, and these should therefore now be thinned out, leaving such as are largest and best separated. As a rule, one to a shoot is sufficient ; but this greatly depends on the condition the plants are in, the extent of feeding ground allotted to them, and other circumstances of a similar character. Choice stove plants that have been made use of to render conservatories gay should not be allowed to remain out of heat too long, or to stand in a draught, as when that is the case they are sure to suffer injury, although they may not show it at once. Allamandas, Stephanotis, Clerodendron, Balfourianum, Bougainvilleas, and Dracænas may be allowed to remain for some time to come, as a conservatory temperature just suits them at this season, and enables them to remain in bloom much longer than they would do in the close, moist heat of a stove.—J. S.

Everlastings for Winter.—Rhodanthe Manglesi is one of the prettiest of all annuals for decorative purposes indoors, and forms charming, neat little groups for small stands or vases, where, when laden with lovely pink, satiny-looking flowers, it is highly effective. The variety, named Prince Bismarck, is very desirable, being more double and having the merit of lasting longer in bloom. To get them to bloom early in spring, at which time they are most valued, seed should be sown in August, and the plants wintered on light, airy shelves near the glass in a warm house where the temperature does not fall much below 50°. Rhodanthes delight in rich vegetable soil, and should be potted in a mixture of at least half leaf-mould or peat and loam in well-drained pots. Any cold frame, where they can be shut up early, will suit them at this season if not kept far from the glass.

Flowers for the Greenhouse in Winter. — Schizanthus papilionaceus and retusus form beautiful pot plants that bloom profusely and are highly ornamental, especially the first-named, the flowers of which bear a close resemblance to butterflies, so rich are their markings. Both varieties are very bushy in their habit, and range from 1 ft. to 2 ft. high, so that they are well adapted for small houses and for window decoration, where, from their gay colours, they are sure to be highly appreciated. Sown in autumn, they are easily wintered in an ordinary greenhouse, and then come in at a time when flowers are scarce. To have fine specimens they should be grown three in a pot, and if of mixed colours, as they are almost sure to be, they will be all the more interesting and make a better display. Schizanthuses are plants of very easy culture, and will do well in almost any kind of soil that is open and free.

Fuchsia Rose of Castile.—Permit me to add my testimony to that of other correspondents in Gardening as to the value of this fine old variety of Fuchsia. It is not only well adapted, as your correspondents point out, for large or small specimens in pots, but likewise for bedding-out in sheltered beds or borders. Its peculiar combination of violet and white renders it most attractive and pleasing. Like many other varieties, it has far more colour in the open air than under glass ; it is also, if possible, even more floriferous, being almost all flower. When planted out the habit is compact and dwarf, and it is equally adapted for dwarf masses or lines. This Fuchsia is seldom seen to more advantage under glass than in 6-in. pots trained in the form of dwarf pyramids, with the lower branchlets drooping over the sides of the pots. It also looks magnificent grown in 12-in. or larger pots in huge pyramids from 6 ft. to 9 ft. high, and 3 ft. to 5 ft. through at the base, and literally clothed with blossom from head to foot. There is no Fuchsia in existence that has a better habit or is more admirably adapted for working up into huge specimens than the Rose of Castile. We flower most of our finest specimens twice a year, first in May or June. As soon as they begin to lose their freshness the whole of the flowering shoots are pinched back, each seed picked off, and the plants set out-of-doors till the middle of August. Placed under glass and liberally treated with manure water, they flower again from September to Christmas in greater beauty than before. This grand old Fuchsia is also

admirably adapted for forming standards, throwing up a young single shoot straight to a height of from 3 ft. to 6 ft. or any intermediate height. Stop the leader at the desired height, and allow three, five, seven, or any required number of shoots to break and be trained as near as may be at right angles with the stem as flatly as possible, and to 3 ft. or more in length. It is important to keep the crowns as level as may be. When the top breaks next season the shoots may be allowed to rise to a height of 1 ft. or more, and then droop gracefully over the sides. Treated thus, they form splendid tops smothered with bloom, and have a very handsome appearance. The simplest way of keeping the crowns in position is to train them across an iron hoop, which becomes entirely hidden beneath the foliage, branchlets, and flowers. At the risk of being written down as of antiquated taste, I would still recommend Souvenir de Chiswick as the best companion Fuchsia for Rose of Castile, and one of the finest in cultivation. It is not only admirably adapted for all purposes here suggested for Rose of Castile, but also for the furnishing of baskets and rafters, for which purposes these and other Fuchsias are so admirably adapted. Those who remember the baskets of Fuchsias suspended from the rafters of the Crystal Palace in its early days must often have marvelled that they are not more frequently employed for roof furnishing. — D. A graceful Cyperus (Kyllingia monocephala).

A GRACEFUL CYPERUS.

(KYLLINGIA MONOCEPHALA.)

This plant is not generally known in gardens, although a few examples of it may have been seen in the Palm stove at Kew for ten or twelve years, and it has elsewhere been cultivated as a graceful and distinct decorative plant. Within the last few years it has been brought into notice by Messrs. E. G. Henderson & Son, who exhibited specimens of it at South Kensington, where it was much admired, and where the accompanying sketch was taken. The plant produces a tuft of drooping or arched Grass-like leaves, from which spring slender, triquetrous stems, bearing cone-shaped, silky heads (as shown in the annexed engraving), from the base of which two or three slender drooping bracts are produced, and which, in their fresh leaf-like greenness, contrast well with the silvery-tinted down-like inflorescence. The plant succeeds well in a warm greenhouse temperature, and grown in small, say 4-in. pots, forms pretty little specimens 1 ft. in height, admirably adapted for decorative purposes. Almost any light and porous compost seems suitable to its growth if placed on a well-drained bottom, and, like nearly all other Cyperads, a copious supply of water is requisite while the plant is growing. There are said to be upwards of fifty species of Kyllingia, the greater portion of which are natives of Brazil and South Africa, and a few belong to Australia.

B.

Gladiolus Colvillei albus.—Everyone who desires large supplies of cut flowers for bouquets or the drawing-room should grow this chaste Gladiolus in quantity. At the present time we have this and G. byzantinus, a rich purple, in full flower, and find them invaluable for dressing small or medium-sized vases. Moreover, they travel well, and the unexpanded blooms open after the stems are placed in water. They are extremely cheap. Their culture is simple, and, like all the bulbous tribe, they increase in quantity under good management. On the warm sand at Cheltenham, last year, I saw a dense row that had stood for three years without protection; but on our cold calcareous loam, where we suffer more from wet than frost, I lift and dry the bulbs, and store them safely away from frost. In January I place eight or ten bulbs in 6-in. pots, filled with light, rich soil, and bury them in leaf mould in a cold pit, where they remain undisturbed until March. They are then uncovered, watered for the first time, hardened off, and planted out in April. Although the autumn-flowering varieties are well known, and such varieties as Colvillei, cardinalis, and insignis (known as Cornflags) were found in large masses in every herbaceous garden years ago, the modern bedding raid has driven them out of cultivation, and many of the rising generation of gardeners are not even aware of their existence; but the return to hardy plants will soon bring them back to our gardens, as they are plentiful enough on the Continent, and every enterprising nurseryman will henceforward give them a prominent place in his autumn bulb catalogue.—W. C.

Insects in Greenhouses.—Being a reader of Gardening, I find that many are in the same dilemma that I was in some time ago when managing some greenhouses for a friend of mine. We had green fly, red spider, thrip, &c.; we boiled some Quassia chips and Tobacco together for them; this was not perfect. One day being very much annoyed at the sight of these pests, I, unknown to the proprietor of the greenhouse, bought 1 oz. of Castile soap, shaved it fine into a bucket, poured some boiling water upon it, and with a few bent sticks in the shape of a whisk I beat it up to a lather. I must certainly say it was very strong for the trial, and I found was instant death to the insects. I afterwards syringed some Roses in full bloom with similar results, killing the green grubs that were in the ends of the young Rose shoots; we had over 1000 Roses out-of-doors and a quantity in the houses. I afterwards dipped Cinerarias, Pelargoniums, Fuchsias, &c., and in short I syringed every thing in the houses and out that was affected with insects. It does not injure the bloom of any flower; I have used it on almost all delicate flowers in bloom for experiment, and I find it only kills the pests, and makes the plants clean and vigorous. With what is spared you can water the plants; it will do them good, and kill any insect in the soil in the pot. Where the red spider is wash the house with a brush and cloth as a woman would the floor; it will lather freely and clean anything. It will keep good no longer than soap-suds—in about a week it it will begin to smell offensive, but it is then good for manure. It is only 1d. per oz., and you can make the wash of any strength you like. All the gentlemen's gardeners about my neighbourhood use it, but do not make it known. The way to dip the plants is, get a vessel deep enough, and place something over the top of the pot, and turn it upside down, and then the fly is seen. Some thin wood or card-board will make a cover for the pot to keep the soil in.—J. W.

ROSES.

TREATMENT OF TEA ROSES.

All Tea Roses should be grown on their own roots, and for several reasons. The point of union of the bud and the stock is mostly the weakest, that is, the most tender part of the entire plant. It is just there that most of them perish. Plants on their own roots have no such weakness, and of course are so far more likely to escape destruction; besides, such plants are much more easily protected. It is somewhat difficult to protect standards of any height, but dwarfs are readily sheltered, nor is it needful to protect the whole plant. If from 6 in. to 12 in. above the collar are preserved intact, there will always be a sufficiency of breaks below that point to furnish a good supply of wood and bloom, or if not the safety of the plants will at least be insured. This would prove exceedingly comforting to many this year who are sorely discouraged by the number of blanks on their Rose beds, borders, or walls. There is also another obvious means of protecting Tea Roses, and that is by wintering them under glass. It is astonishing how many Tea or other Roses may be kept in a small area of glass in small pots, and how well and how freely such plants grow and flower if planted out in good soil after the severities of the weather are over. Of course this plan of treating Tea Roses assumes that many of the old plants may be lost. But this need not be so. The spring planting of Tea Roses may proceed abreast with their protection in winter. Should both plans succeed, the result would only be the highly gratifying one of a double supply of Tea Roses; should either plan fail, our gardens would still be fairly furnished with Teas.

There is also but little difficulty in keeping up a supply of Tea Roses, as no Roses strike more readily just after the first flush of flowering than Teas. Moderately strong shoots taken off with heels and inserted in a bottom-heat of 60° or so, kept close and shaded from bright sunshine, will soon root in sandy soil. As soon as rooted pot off singly in 4-in. pots, drain with ½ in. crushed bones, and the soil can hardly be

too rich. One half of rotten manure to a half of good loam, and freely mixed with sharp sand, is a good compost. Keep them pretty close until rooted in their new pots, then give all light and air possible. See that the plants never flag for lack of water. Remove all flowers as they appear, and if any shoots run up weakly let them be stopped, so as to force the production of from three to five shoots, if possible, of uniform strength. Gradually inure them to the open air, and ripen the growth made as far as possible before the end of the season. Winter them in cold frames or houses in order that the plants may be kept from frost. They must also be kept very cool in spring, so that the buds do not break till after the plants are put out and the roots are at work in the new soil. Tea Roses treated thus mostly grow and flower with a luxuriance and a beauty unknown to many people who have Tea Roses in the open air, and who have had to battle with the severities of the winter.

Easy Way of Propagating Roses from Cuttings.—About six weeks ago I took two cuttings of Maréchal Niel Rose, ripened wood slipped from the main stem, about 6 in. long, and put them in a wide-necked bottle full of water, setting them near the glass in the greenhouse; they have now made good shoots and thrown out roots, and I have planted them in small pots, in which I shall keep them till next spring, when I shall turn them into the ground by a wall. I have a good sized Tea Rose bush which I raised thus some years ago. They would do equally well in a window in a room, and require no attention beyond keeping the bottles full of water. If a few pieces of charcoal be placed in the water they will keep it from smelling offensively.—S. M. M.

Sawdust in Gardens.—My experience on the above subject is very different from that of "Solicitor's Clerk." I have found sawdust to be very useful in correcting the stiffness of clay; not clayey soil, but actual hard subsoil clay—the parings of a stone quarry which were used to fill up a brick pond, which was formerly where my garden is now. Of course I did not use the sawdust pure and simple. This is how it is. You are aware that in Hull (near which town I live) there is a vast quantity of timber cut up, and the poorer class of horsekeepers have been in the habit of using sawdust to make the horses' beds. The prejudice against sawdust on land causes the manure thus formed to be very cheap, and some of it fell to my share for the carting. I had it thrown down on a piece of vacant land and let it lie to rot. I afterwards scattered it about very freely, as far as I could throw it with a shovel; the other parts of the same land were well manured, and had plenty of riddled ashes, but in taking up the Potatoes planted on the plot I can tell by the beneficial result wherever the sawdust has reached. The Potatoes turn out finer and cleaner, the land is drier and easier to work, and there is an absence of the long thick earthworms so plentiful over the rest of the plot. I do not enter into all the minutiæ of the case, as that would take up too much of your space, but I am satisfied that sawdust properly used is an article of great benefit to stiff, retentive soils. Further, I think "Solicitor's Clerk" ought not to be annoyed because another man's experience is not the same as his own. By your kindness we are allowed to write in your journal for each other's benefit. Let us agree to use the privilege in the spirit in which it is granted.—Roadside Cottager.

THE SHRUBBERY.

Moving Shrubs.—It is not uncommon in amateurs' gardens to see shrubs which at first, when small, were planted close to give immediate effect, with a view to some being thinned out as they got larger, left until they spoil each other. If, in the first instance, the work were done with judgment, those which were intended to remain permanently will have been put in such position as will afford them enough room by simply moving the others of less value, which were only put in to fill up for a time; but it frequently happens that this course has not been followed, and that the planting has been done indiscriminately, in which case when they are grown so as to be too close, a portion has to be taken out, and many required to remain want moving more or less from the position in which they were first planted. Where removal of this kind becomes necessary, it should be carried out before the shrubs have grown into such a crowded state as to injure the whole, as frequently permitted; for, independent of the injury inflicted upon all, the longer moving is deferred, the worse condition they individually get into for removal. There is no time in the year when evergreens can be more successfully transplanted than from the end of August to the beginning of October, but the earlier in September the better; there is no necessity to wait for showery weather, not even if the soil be apparently so dry as to contain little moisture. In fact, the heat that is in it when in this state is one of the first requisites as regards success, on account of its assisting to promote the immediate formation of roots; whereas if removed late in autumn, when the temperature of both the air and earth is reduced by waning sunheat and chilling autumn rains, all this advantage is lost. In planting, however, whilst the soil is in the dry condition above described, it is imperative that every plant should be thoroughly soaked with water when it is replanted. This should not be done by half measures; on the contrary, the whole of the soil that is put in round the roots down to the bottom of the hole should be effectually moistened. Where this is done the formation of new roots, as I have said, commences immediately, and this single thorough watering will generally be found sufficient. If any doubts be entertained as to roots being formed immediately after planting at this season, an inspection, say a month afterwards, will soon dispel them; for those who will take the trouble to look at the point of every root that has been severed will observe a quantity of young feeding fibres which will enable the plant to resist the most severe winter that may ensue, and ready to supply the demands made by spring growth. Each shrub as soon as it is taken up should be immediately re-planted, not allowing the roots to have time to dry; in this there must be no delay; indeed, this early removal is only to be recommended where shrubs can immediately be placed in the new positions assigned to them from one part of the garden or pleasure ground to another. Presuming that the surplus plants thus taken up will be again planted where more space can be found for them, ground for them should be prepared beforehand by sufficiently deep digging or trenching, so as to expedite the work.

The Ash and Holly-leaved Berberries.—The Ash-leaved Berberis (B. nepalensis) is a plant in warm southern districts. Its leaves, which resemble in shape those of the Ash, are of a deep green colour and glaucous on the underside. Its flowers, which are large and yellow, are produced in long racemes. The fruit is oblong and dark purple. Our illustration gives a good idea of what the plant is like; and we have only to add that it should never be planted in cold wet districts, or in clayey soil. The Holly-leaved Berberis (B. aquilifolium), on the other hand, may be planted in almost any position or in any kind of soil with a certainty of its succeeding. In positions exposed to the sun it bears its purple fruit in abundance, which, contrasted with the shining green leaves, renders the plant a handsome object. It is planted largely in woods in some districts as coverts.

Nepaul Ash-leaved Barberry (Berberis nepalensis); a fine shrubbery plant for southern counties.

Golden Yew on Common Yew Hedges.—Grafting the Golden Yew here and there on shoots allowed to grow up from hedges of the common Yew is frequently practised in the great Surrey nurseries The practice deserves adoption in private gardens.—V. E. R.

Balsams in the Open air.—Balsams have made a strong growth in the open ground this summer, and are now blooming splendidly. Those whose notions of Balsams are taken from meagre plants, half-starved in small pots, can have little conception of the size and vigour they exhibit in the open ground; the stems are so large and massive that they resemble miniature trees. Unless the season be more than usually hot and dry the soil in which Balsams are grown need not be too rich. Ordinary garden soil suits them admirably, as if too rich the growth becomes coarse and rank at the expense of bloom. The best effects from the Balsam are got by putting into clumps some half-dozen or so of plants of the same colour, and alternating pale hues with dark or rich coloured ones. Planted in this way they are much more effective than when indiscriminately mixed in a bed. The Balsam is not a gay plant in the same sense that scarlet Pelargoniums or yellow Cal-

ceolarias are, but is modestly pretty and never vulgar. Those who want a blaze of colour will not care for the Balsam, but all who like a pretty and quiet display of flowers, such as the most fastidious in garden decoration may look upon with pleasure, will find the Balsam a plant admirably suited to evoke satisfaction. If it be objected that the Balsam needs a carpet of some neutral tint, then patches of green and grey Sedums will give the desired hues at once. I find the plants invariably do best that are dibbled out from the seed-bed when strong; those first potted up make such a profusion of side growth that the plants become a dense bush of leafage, and the bloom comes late and is much hidden. In the other case the plants assume a pyramidal form and show the spikes of bloom to great advantage. The best colours for outdoor planting are self, such as pure white, pink, peach, purple, carmine, scarlet, and crimson, but the flaked and spotted kinds are very pleasing.—A. D.

Notice.—We this week have the pleasure of presenting our readers with a plate of Roses, drawn life-size by Mr. A. Parsons. It was our intention to have presented this plate with GARDENING early in spring, but at that time only 30,000 of the plates were ready, and these not being sufficient for our then issue, we had no alternative but to offer the plate in limited numbers with our index, and wait till a number of plates sufficient for our weekly issue could be got ready. As most of our readers are aware, this plate of Roses forms the frontispiece for the first volume of GARDENING ILLUSTRATED, for which an index is obtainable. Those who already have the plate with the index will probably value the present copy for other purposes.

ANSWERS TO QUERIES.

2628.—**Mildewed Strawberries.**—The cold wet weather is the most likely cause. The plants should be renewed from fresh runners every three years. The best practice is to strike a lot of runners every year in small pots or on pieces of turf, planting these out every autumn in moist, firm, well-manured soil, so that the stock always consists of one, two, and three-year-old plants, one-third of each. The rows should be wide enough apart to allow of plenty of manure being worked in between the rows during the winter without disturbing the roots.

2631.—**Cut Roses in Water.**—Both sal ammoniac and sulphate of ammonia have been recommended to be mixed with the water to prevent cut flowers from flagging quickly. I have tried both, but without any beneficial result. Stopping the cut end of the stem with sealing wax has also been recommended, which has also proved a failure with me. For bouquets the best way is to tie them up as tightly with a piece of string as possible without bruising the stems. When cut Roses flag as described the Roses themselves are generally weakly; when growing vigorously, and cut with a piece of stem attached, they will frequently remain fresh several days. I have cut flowers which lasted three or four days, and others which flagged immediately from the same plants this year.—J. D.

2665.—**Rhododendrons not Flowering.**—Rhododendrons ought to do better near the sea than anywhere else, as a moist atmosphere is favourable to them. The soil must be unsuitable, as the plants are described as starving, if by weak and wiry is meant having long naked branches with only a few leaves at the tips. If the sand is calcareous, which it will be on many coasts, there is no help for it but to prepare a special soil, as lime in most forms is poison to Rhododendrons. If the sand is silicious, it may be too poor, and the very best procedure in that case would be to mix it well with peat broken into small lumps, heath-mould, or the Grassy top-spit of an old common or waste. Rhododendrons require a light sandy soil, which their hair-like roots can easily penetrate, containing plenty of vegetable matter in a state of decay, and a considerable amount of moisture in the air and earth. As a rough and ready method of testing the soil for carbonate of lime, wash some of the sand perfectly clean, procure some hydrochloric acid (spirits of salt) and drop some of the sand into it; if a violent effervescence takes place from the particles the sand is probably carbonate of lime; if it remains unaltered it is most likely silica, which is beneficial. It will not do to test the whole of the soil in that way, as it will most likely contain alumina and other ingredients, which will also effervesce. I cannot remember seeing Lime trees grow to any size very near the sea.

2739&2744.—**Cyclamens not Growing.**—The Persian Cyclamen is a very easy plant to grow and to keep if its requirements are attended to, but resents mismanagement by producing few and mis-shapen blooms, and by dying off. The best time to sow the seed is in spring or early summer in pots or pans of light loam, silver sand, and leaf-mould. The seed is some time in germinating, as a minute bulb is first formed underground. No heat is required unless the seed is sown very early in spring. They do very well in a shady corner of the greenhouse. After the little plants have made one or two leaves, they become dormant and cease growing, and should only have just as much water as will keep the bulbs from drying up. The last week of August they should be lifted from the seed-pans and potted into their blooming pots. This may be done at any time while they are dormant. The compost recommended is equal parts of loam, leaf-mould, and well-rotted manure, with a very little sandy peat. The pots should be placed in the open ground, but not exposed to frost till the leaves are well formed, when they may be placed in the greenhouse until their flowers show. This is the difficult period to manage them in, as they must be kept airy and cool at a time when the weather is cold and inclement. A steady temperature of 60° suits them exactly. They require, particularly in November and December, free air and coolness till the leaves form, then warmth till they flower, and shade, air, and coolness while in flower. When the flowering is over, the water given should diminish in quantity until the dormant period begins, when the leaves die. Seedlings usually produce a few flowers the second year, but it is three years before they flower well. A little fresh compost should be added every year, but otherwise the plants may remain two or three years in the same pots. I found they could not be managed in a sunny, unheated greenhouse, the temperature was too fluctuating; and I should think they could not be grown in a cold frame, as they require a higher temperature than can be got in winter without artificial heat. In watering Cyclamens it is better not to wet the leaves, but float the water on to the earth of the pots from the spout of the watering-can or from a jug.—J. D.

2740.—**Vegetable Marrows.**—Many plants in which the male and female flowers are separate have the two kinds of flowers in varying proportions from all male to all female—there is no help for it. I remember noticing a kind with very large flowers which seemed to be bi-sexual, at least every flower seemed to produce a fruit, but as I only saw them from a distance, I cannot say with certainty if such was the case. They were purchased as plants. Perhaps some other correspondent will say whether there is such a variety and what is its name. The flowers I saw were 6 in. or 7 in. across.

2733.—**Club in Cabbages.**—I have entered this year on possession of a garden in which I was told Cabbages all took the club, so that it was no use trying to grow them. Knowing that undrained land predisposed Cabbages to be attacked in that way, and finding Rushes and other marsh plants growing, I trenched the land three spits deep, and dug a ditch 4 ft. deep along one side of the vegetable plots. I mixed a puddle of clay, soot, and Gishurst's compound, and dipped my own seedlings in that up to the first pair of leaves, allowing it to become nearly dry before planting. Some purchased plants were planted without that treatment; both are doing well and hearting nicely, and I have seen no sign of club yet, which in the same ground formerly attacked the plants in a seedling state. My purchased plants, were purposely planted on ground on which the previous crop had been Cabbages. Last summer the ground was unoccupied. The club is the grub of an insect which attacks the roots of the Cabbage family, forming a species of gallnut, and preventing the further growth of the plant by devouring its juices. The dressing I used is said to protect the young plants; it should be mixed as thick as practicable. Messrs. Sutton, of Reading, recommend rotation of crops and deep cultivation as a remedy; of course that would mean never planting any of the Cabbage family two years running on the same ground, and if three or four years intervened between each crop so much the better.

2737.—**Propagating Roses.**—The best way of propagating Roses of all sorts is by layering from dwarf plants exactly as Carnations are layered. The shoots should be nearly ripe to be suitable. August and September are the best months for the purpose. For more difficult modes of procedure, with the advantages and disadvantages of each process, procure "The Amateurs' Rose Book," Groombridge & Sons, which contains full practical details of all methods of propagation.—J. D.

2719.—**Rose Eaten by Insects.**—There are several moths whose larvæ feed on the Rose, such as the Bergmannian Tortrix (Crœsia Bergmanniana) and the Brown Cloak (Spilonota roborana). These belong to the family of the Tortrices, all of which are very small insects. S. roborana eats into the buds as well as the leaves. Perhaps one of these may be the insect spoken of by "H. B.," which eats half through the shoots.—R. T. N.

2722.—**Rusty Water.**—Iron in moderation is not injurious, being frequently prescribed as a medicine. What are called chalybeate springs, such as Tunbridge and Cheltenham waters, owe their curative power mainly to containing iron. Water even considerably discoloured by iron rust is not nearly so dangerous to drink as water carried in lead pipes; 300 yards of them would render the water poisonous. The only remedy would be to have the pipes coated inside with a silicate paint; common paint would not do, as that is nearly all lead. Iron pipes tinned inside would also be safe, as would glass tubing cased in iron. Suitable pipes are almost certain to be obtainable; consult the building papers.—J. D.

2693.—**Mushrooms on Lawns.**—The pretty little Champignons, or Fairy Ring Mushrooms, would do well on a lawn in a country district, besides adding a kind of interest by the fresh green rings they produce on the turf.—J. D.

2663.—**Vegetable Marrows Dying Off.**—Vegetable Marrows often behave in that way in a cool, wet summer like the present. It will not mend matters to remove the false blooms, as they are the male ones, and the more of them in a wet season the better, as the pollen is liable to be drenched and made useless.—J. D.

2681.—**Strawberries in Heaps.**—I can inform query 2681 that rats are the "invisible agency" by which his Strawberries were piled up, as I have seen it done by those animals.—HESPER.

2809.—**Laburnum Flowering Late.**—*Enquirer.*—It is not at all unusual for the Laburnum to throw out a few flowers in late summer and autumn.

2810.—**Pruning Espalier Apple Trees.**—*W. C.*—Cut back all the long shoots not required for extending the height or breadth of the trees within two eyes of their base.

2811.—**Cutting Leaves off Peaches.**—*M.*—It is not very good practice to cut leaves off Peach trees to any great extent, even to expose the fruit, but it is sometimes necessary to cut some of the leaves in half in order to fully expose the fruit to the sun, and it does little or no harm if done discriminately.

2812.—**When to Dig up Potatoes.**—*Subscriber.*—Lift a root, and if the skin is firm on the Potatoes and not easily rubbed off with the thumb, then they are ripe, and may be dug up, left on the ground to dry for a few hours, and then be housed.

2813.—**American Cowslips** (Dodecatheons).—*M. P.*—These are perfectly hardy in well drained soils and slightly sheltered situations. We do not recommend tradesmen.

2814.—**Roses in Pots.**—I have some Hybrid Perpetual and Tea Roses which were bought some last autumn, the rest last spring. They were in a greenhouse and bloomed well. Then they were put out, and now are plunged—still in their pots—and well mulched with good manure. They have not been potted or pruned since I got them, and have all made good growth. I intend layering some of them. Can I layer into pots plunged alongside? and when should they be repotted and pruned? They will be indoors next winter in a cool greenhouse.—HESPER. [Yes, you can plunge pots by the side of them, and layer them, or make a bed of sandy soil on each side of the plants. They should have been repotted after flowering. We would advise you to take off some of the surface soil, and top-dress them with fresh rich material. Prune slightly when you take them indoors].

2815.—**Carnations with White Petals.**—*M. A. W.*—Self-coloured Carnations often produce

flowers in which are a few petals of different colours. The whole of the Pink family is very subject to sport in this way.

2816.—**Wild Mullein**.—Can any correspondent inform me where the Mullein (Wild Plant) generally grows, and the height of the plant, and what sort of blossoms it bears?—S. M. A. [There are six species of Mullein or Verbascum indigenous to Britain. They are tall-growing herbs with yellow, brown, or purple flowers. Most of the species are natives of Central Asia and North Africa.]

2817.—**Vine for Greenhouse**.—*J. J. C.*—The best kind you can have is Black Hamburgh. Procure a good, strong, well-ripened cane at any good nursery, and plant in September or October.

2818.—**Clematis after Flowering**.—*St. E.*—We presume the Clematises are planted out, in which case let them alone. You can put a coat of coal ashes over their roots in winter, and in spring cut out weak growths and prune back a few of the strongest shoots, in order to keep them clothed with foliage from the bottom.

2819.—**Storing Seeds**.—I have placed my Potatoes, Peas, and other seeds for next year over a stable. Is it likely that the ammonia which arises from it will affect them in any way?—W. B. D. [We should think not.]

2820.—**Vine Borders**.—What compost would you recommend for a Vine border. Last spring two Vines were killed, apparently by a yellow slug, which I collected in hundreds, and all my Vines more or less suffered. I want to make an entirely new border; will you therefore tell me what compost to use?—T. F. [Use good turfy loam from an old pasture mixed with a little well rotted manure and crushed bones.]

2821.—**Coal Tar**.—Will this hinder sheep from eating the bark off forest trees? and will it injure the trees themselves?—Hortus. [It would probably injure the trees. Better tie brushwood round them till they get beyond being eaten.]

2822.—**Cucumbers and Vegetable Marrows**.—*W. J. A.*—In summer bees and other insects will do all that is needed. In the case of early Cucumbers artificial fertilisation is necessary.

2823.—**Club in Cabbages**.—I have a large plantation of Cauliflowers, Savoys, Brussels Sprouts, &c., the leaves of a large number of which are turning yellow, and on pulling them up I find the roots to be what is locally termed club-rooted; some roots are as large as a full-sized Turnip. What is likely to be the cause?—W. B. D. [It is the work of an insect. Use plenty of wood ashes on the land and in the holes in which the plants are set.]

Eucharis.—*A. K.*—See recent numbers of Gardening. The flowers of Eucharis are not sold in Covent Garden in bunches, but by the dozen blooms.

Morello Cherries.—*A. E. C.*—Send samples to Mr. Webber or any other fruiterer in Covent Garden market, and they will probably tell you what they are worth.

Brondesbury.—Kindly observe our rule and ask your questions separately.

QUERIES.

2824.—**Grape Vines Infested with Red Spider**.—I have a house of Black Hamburgh Grapes which looked well to within the last ten days, and look at present in a fair way of colouring, but I am afraid they will not come to perfection, the wretched little insects are making such skeletons of the leaves. I have syringed the Vines once a day when I closed the house, between 4 p.m. and 5 p.m., until the fruit showed signs of colouring, and I have occasionally since poured water in alleys and syringed the walls. Will some reader inform me how I can get rid of this destructive pest, and insure the present crop?—T. R.

2825.—**Poplar Roots in Lawns**.—Can any one kindly inform me how to destroy the roots of Poplars that have completely undermined a bowling-green? Suckers come up from the roots in bunches at various intervals, and form hard knots when cut down, that injure the mowing machine, and are very unsightly.—Subscriber.

2826.—**Nesida Rose**.—Can any one tell me where I can procure a Nesida Rose, the sweetest climber I know? I have applied for it in many places without success.—A Subscriber.

2827.—**Saving Flower Seeds**.—Will some one afford me a little information as to the saving seeds of plants, more particularly double Stocks?—Tyro.

2828.—**Caterpillars on Geraniums**.—My Geraniums in the open garden are infested with caterpillars; and although I pick off all I can see one morning, there are more the next. Is there anything I can do to keep them from getting on the plants?—W. D.

2829.—**Hibiscus africanus**.—How can I grow this plant? This year I have planted seed bought at two different places, and none has come up.—E. G.

2830.—**Greenhouse Carnations and Pinks**.—Will some one tell me how to grow Clove-scented Carnations, Picotees, and Pinks, in a greenhouse? Also mention a few of the best, and how can I get plants that will flower in the middle of next winter?—Christmas Rose.

2831.—**Sowing Anemone Seed**.—Will some one kindly inform me when and how to sow Anemone seed?—F. E.

2832.—**Dirty Flower-pots**.—What is the best way to remove the green substance from the outside of flower-pots, and what is the cause of it?—F. J. L.

2833.—**Preserving Vegetable Marrows**.—At what age is it advisable to pick the Marrows? Also the mode of proceeding to preserve them as a substitute for preserved ginger. Also, are the Marrows that are intended to be kept for winter cooking best hung by the stem or slung in tapes or cloths?—Amateur, *Cardiff*.

2834.—**Garden Refuse**.—I have a large quantity of garden refuse, such as Cabbage leaves, Turnip-tops, &c. Is there anything that I can apply to facilitate the decomposition without giving rise to any offensive fumes?—Amateur, *Cardiff*.

2835.—**Sowing Flower Seeds**.—Will some one kindly inform me if by sowing now I can raise any of the following in a cool frame? If not, what is the best time for sowing, and what kind of soil should I use for the purpose?—Carnation, Calceolaria, Cockscomb, Lobelia, Pyrethrum, and Pelargonium.—J. T. M.

2836.—**Magnolia not Flowering**.—I have a standard Magnolia which for many years was covered with flowers. Of late it has not had any at all, though apparently still quite healthy. Can any one suggest a likely cause of this?—E. B.

2837.—**Plants for Aquarium**.—I have made a square aquarium, with roof, &c., and have placed in it a piece of rockwork to represent two arches. Over the centre of the middle pillar I have a fountain playing, and over each arch I have made a flat stand for to place a flower-pot on. I am desirous of having a plant of some kind growing over each arch which is bushy, and which will grow down and thus hide the pot. I also require a creeper to plant in the bottom of the aquarium to climb up the rockwork. Will some one kindly give me the names of the plants most suitable for the two respective positions, and that will throw off the most oxygen?—Ferry Hill, *Durham*.

2838.—**Beard's Vineries**.—Mine is a Beard's Patent Vinery, felt and screws being used to secure glass and iron. The felt perishes quickly; can any substitute be recommended in its place?—F. H.

2839.—**Thrips on Orchids**.—Can any reader inform me whether there is any real cure for the yellow thrips [White Scale.—Ed.] which do so much damage in Orchid houses? Fumigation, I find, is powerless to destroy those which are lodged in the crevices of the sheaths and folds of the leaves; and plunging the foliage of the plants in Tobacco water, although effectual in killing the thrips, is, I find, very hazardous. Is there no other solution which will not injure the Orchids, but which will destroy the thrips? Has Quassia solution ever been tried? I find a camel's-hair brush very useful for fetching them out of the crevices where they collect, but I fancy the only effectual remedy would be some liquid in which the foliage could be dipped.—C.

2840.—**Unproductive Potatoes**.—I shall be obliged if some one will explain how it is that some Scotch Champion Potatoes growing in three different parts of my garden show no sign of tubers? Here and there is one the size of a pigeon's egg, and that is all. The haulm is splendid, in some places 4 ft. high. Will they bear a crop, or had I better dig them up?—A. E. C. S.

2841.—**Houseleeks**.—I have a very flat roof, and I have planted on it a plant of the common Houseleek; it has grown well and flowered freely this year. Are there any other sorts of the Houseleek that would do well in such a position? Mine has a large pinkflower with a yellow centre, and the flowers are in clusters. Are there any other coloured flowers of the Houseleek?—Housleek.

2842.—**Cleaning Garden Pots Equal to New**.—Will T. Brown, query 1895, kindly say if the hydrochloric acid is hurtful to the hands or at all dangerous to human beings or animals? also would it answer to put the solution into a galvanised pan? Would it damage the galvanising on the pan?—A Learner.

2843.—**Fruit of Tacsonia mollissima**.—Is this edible either cooked or fresh?—Tacsonia.

2844.—**Creeping Jenny**.—Can any of your readers inform me if it is usual for the above to be attacked by white blight? I have some in pots, and I keep them plentifully supplied with water, which I have always understood they required. Is rich soil necessary?—Marguerite.

2845.—**Mushrooms in Boxes**.—In your impression of Aug. 7 (p. 268), I see a short account headed "Growing Mushrooms," and signed "J. C." I wish he would state what sort of rotted manure he uses, as well as the nature of the compost used, and whether firmly pressed into the box or not, and as to the quantity of spawn, watering, or any other particulars with which he may be pleased to favour me.—J. Hind.

2846.—**Heating Small Greenhouse**.—The size of my greenhouse is 14 ft. by 7 ft. Last year I tried to heat it with a paraffin lamp, but could not obtain sufficient heat. I then tried the inverted flower-pots, as spoken of in Gardening, but with these I also failed through the breaking of the upper pot. This year I am willing to spend a little more money on a good heating apparatus. Will some one recommend one with which they have had experience that will consume refuse?—Pat Rooney.

POULTRY.

Disease in Poultry.—On June 19 I had eighteen strong chickens hatched, and all particularly healthy until the day before yesterday, when almost all showed signs of sickness; two have died, and I fear they will all follow. Is there any epidemic going about amongst chickens? What can be done for them? They stand in a sleepy way with drooping wings, feathers ruffled and puffed-out breasts, and have but little appetite. Any information will be acceptable. I have had a good deal to do with poultry, but never met with a similar case. Is it a delicate time with respect to plumage?—M. J.

Parasites in Chickens.—I should be very glad if some one would kindly recommend a plan for destroying insects in the heads of bantam chickens. I have dusted sulphur into the feathers twice a day, and also rubbed the heads with a strong solution of Tobacco-water, but with no result. The birds are now two months old and extremely choice, for which reason I am particularly anxious to save them. They scarcely eat anything, but are huddled together with wings drooping from morning till night. The first began about a fortnight ago, and the whole brood (ten) are now infested with the vermin, and one of the chickens is already dead. What can have produced them in the first instance? I may add that the chickens are in a roomy and lately white-washed house and have a large Grass run.—W. B. D.

Food for Poultry.—What is the best food (fattening) for ducks? also for laying hens? and how much per week should they cost respectively?—Alpha.

Breeding Ducks.—Will some one kindly give their experience as to the advantage of crossing the Aylesbury Duck with the Rouen Drake? Will the ducklings be white?—R. M. S.

Chickens Laying Early.—Two of my pullets, which were hatched in the second week in March, commenced laying the third week in June, and still continue to lay. One is a pure Houdan, the other a cross between a game and Dorking.—A. H.

BEES.

Fumigating Bees.—Mr. Letchford assumes that the method of rendering the bees in a hive insensible that I recently advised is incorrect. I can assure him that the operation has been done often with a straw skep, and that, too, successfully. The bees have been with a very tiny piece of fungus sent to sleep in a few moments, and all got out of the hive in a few more moments without trouble. It is not fair hastily to assume that because he may have been unable to do this others must have been as unsuccessful. I write now chiefly to note how much the bees are favouring the Mignonette flowers. I can conceive of no garden plant that supplies richer store of both honey and pollen than does this sweet annual. It is also a long season flower, and a mass of it must indeed be a rich feeding ground. Fortunately this plant may be had in abundance in all gardens; this summer it is especially good, growing and blooming most luxuriantly. I notice further that bees, when gathering food, keep to one kind of flower only. No doubt to this important fact do we owe the general absence of intercrossing that might well be looked for. Where bees are active amongst flowers, many come in covered with yellow pollen. These have been exploring the male flowers of the Vegetable Marrows, and perhaps the Cucumber, large breadths of rich Cucumbers being grown near to my bees. Others have a gray pollen; that is no doubt gathered from the Onion blossom, as a large quantity of these bulbs are grown for seed a few fields off. The insects work the heads of flower most pertinaceously. Just now the Runner Bean bloom is furnishing a large quantity of food, as also is the Clover, of which large breadths are now ready to be cut. Watching the flight of bees from the hives, show that by far the larger portion of them take long flights by the height to which they ascend, but a few work close home, and for the sake of these few it is well to sow seed of plants that will in the home garden give as much good food as possible.—A. D.

Bees.—Will you allow me to inform "Novice" that it is not the humane system that he has adopted, but the inhumane one. Like himself I was years now gone by persuaded to do just the same with my poor bees, to my sorrow and their destruction, but I have profited by sad experience, as he hath also done; but let me say to him, don't be discouraged; he will yet succeed, although he has lost a good season as this is for bees, as also a good stock, but he will start next season a wiser man. The "humane system" proper is to super them or to drive them; the first is much the best every way, as he will also prove if he tries it, as he will obtain his honey much sooner and much more pure, and will, if he wishes to sell, obtain double the price. I have been supering my bees for years, and do not think of adopting any other system until I am persuaded that it is a better one. I have this year some good supers—some in straw and some in glass; one of my glass supers took the first prize at a show lately held. The same stock also sent out a strong swarm, so that I have a good stock swarm and super, each of the value at least of 15s., which with the prize of 10s. make the one colony or stock of the value in money of 55s. If the honey was taken from the stock and swarm by driving them out, it would of course increase that sum to nearly £4; therefore bees if rightly managed are very profitable as well as interesting. Being an old bee keeper, I shall be pleased to answer in

quiries in reference to bees for any that may need them.—Apiary.

SNAIL AND SLUG TRAP.

The trap figured below is a very simple one. It consists of a kind of pot provided with a number of holes in the side and a closely-fitting cover, the pot being plunged into the ground so that the holes are just level with the soil. The pot is glazed inside, and the cover is made to fit tightly, so as to keep the bait that is used in a fresh condition. The holes are conical, so that when once the snail enters the pot it has great difficulty in getting out again. The interior, being thus kept cool and dark, has a great attraction for snails, slugs, mole crickets, woodlice, and other plagues which burrow in the earth. As for the bait to be used, that depends in a great measure upon the pest which we wish to destroy. A saucer of strong-smelling stale beer, or beer mixed with vinegar, is an excellent bait for snails, slugs, and woodlice, the olfactory nerves of these destructive pests being particularly sensitive. Stale wine is much used in France as a bait for the mole cricket, and earwigs seem to enjoy fresh bones which have not been too well picked, stale soup, or pot liquor with great gusto. For field mice and other four-footed vermin, flour, meal, corn, or bran may be used. As a rule, the traps should be placed in a shady position, so as to keep them as cool as possible—snails, slugs, and woodlice hating light and warmth. In the case of slugs and snails the greatest harvests ought to be made in damp or wet weather, and approaching showers ought therefore to be the signal for putting fresh bait in the traps. These pots are sold by M. Pelletier, 20, Rue de la Banque, Paris, but they might be easily manufactured by boring a number of holes in a flower pot with an old three-cornered file, the point and edges of which have been well sharpened on a grindstone. If plenty of water, and silver sand be used a hole is very soon made. The cover may be formed of a flower-pot saucer, and should be fastened down with ordinary clay. C. W.

Trap for Snails and Slugs.

Destroying Worms in Pots.—Nothing is more easy than to destroy worms in pots, providing that the operation is properly conducted. It is, however, absolutely necessary that the lime be quite fresh, otherwise the effect is only partial; the worms are merely stupefied for a time, quickly recovering their full vitality. The best way is to procure a peck of lime, in large lumps, if possible, and store it away in an air-tight tub, keeping the same in a perfectly dry place. When lime water is needed, put several large lumps into a pail, and pour just enough water in to cover them. If the lime absorbs the water and still appears somewhat hard, add a little more; cover the pail, and allow the lime to remain untouched for an hour, at the expiration of which time it will be perfectly slaked, and the pail may be filled up with water. Allow the water to become quite clear and transparent before using it, or the surface of the soil will become covered with an unsightly deposit. If a considerable number of plants have to be operated upon, then the better way is to slake a gallon of lime and put it in a large tub, in which a tap should be fixed at about 6 in. from the bottom, so that the water may be drawn off clear. The question is often asked, "How strong should lime water be made?" The answer to this is, that it cannot be made too strong; the water will only hold in solution a certain amount of the properties of the lime; consequently, all that one has to do is to ensure a sufficiency of this latter ingredient, three or four good spoonfuls of which will suffice for twice filling a 36-gallon cask with water. Every pot that is infested should be allowed to thoroughly dry out, and should then receive a complete saturation, enough to cause a free exit of water from the drainage hole. Allow an hour to elapse and then repeat the operation. The little worms will come to the surface and die, and such large ones as do not share that fate will beat a hasty retreat through the bottom of the pot, never more to return. Those who are much troubled by worms entering pot plants would do well to make a practice of watering with lime water. Its constant use cannot in any way prove harmful, for lime, like soot, is rather a strengthening than a stimulating agent, and may be used daily without the slightest fear of ill-effects; on the contrary, plants which may get frequent applications of clear lime water unmistakably show their appreciation of it. For tender-rooted subjects, such as tuberous Tropæolums, Achimenes, Ferns of many kinds, Cyclamens, &c., it is a good and safe manurial agent.—J. C. B.

Plants by Post.—I can strongly recommend the little post hampers made at the workshops for the Industrial Blind, 6, Howard Street, Belfast. They are made in two sizes, at 1s. and at 9d. each, postage 1½d. and 2d. according to size when empty. For cuttings and seedlings, as well as small-rooted plants, they answer admirably, but for cut flowers to go a distance they must be lined to exclude the air. Damp Moss or cotton-wool insures all plants keeping fresh.—Hesper.

Window Ornaments.—I was anxious to make some fronts for my windows of a somewhat rustic nature, in order to prevent the flowers falling off the sills, and to protect the pots from the rays of the sun, so I obtained from a cooper's a shillingsworth of hoops off old vinegar casks (some of the hoops had the bark on and some not). I then cut them into lengths of about 8 in., and pointed them at one end. The frame-work I made from a glass case which cost me 1s. I then fixed the lengths on with French nails, which I clenched at the back. To fasten the whole to the windows I obtained some small brass eyes, some of which I fixed to the framework of the windows, and some to the "fronts," and with some iron skewers I made hooks of the requisite lengths, so that the "points" could be detached when required. I then made a small ornament in the form of a star for the centre, and well varnished the whole. They answer the purpose admirably, and look very well. To the window boxes at the back of my house I made similar fronts to hook on and off, the only difference being that I painted the pieces of hoops at both ends.—A. H. B.

AQUARIA.

I have a rectangular tank, plate glass, holding about 30 gals. Will "W. B." (No. 58) inform me where the Frog-bit, Water Milfoil, Anacharis, and the Vallisneria are to be purchased? There are eighteen carp and five dace in it. It is supplied from a wood tank which is kept filled with river water and conveyed to the aquarium by a length of ⅜-in. pipe, the water falling into the aquarium in a shower of fine spray, whilst the bottom water is worked off by a self-acting syphon—the waste-pipe, and as soon as the water attains its maximum depth the syphon at once works; thus it cannot overflow and the water is also constantly renewed. The fish are splendidly healthy and very lively. They are fed almost daily with a dessert spoonful of vermicelli crushed up and with live flies during the summer, of which they are particularly fond. I have had them two years, and have not lost a fish from ill-health. I am persuaded that the gold fish must be fed, of course judiciously, and also that the plants should be so placed as to enable them to rub themselves; thus they are kept clean and healthy. Our neighbourhood is not rich in aquatic plants, nor can I purchase them here. Can any other of your correspondents confirm "W. B." as to the Virgin Cork being harmless after soaking and drying? If so, I shall introduce it as pots for the plants in preference to planting in the aquarium, as the plants can be more readily removed in pots, and the Cork can be so arranged as to add to the beauty of the interior. My experience is altogether contrary to retaining the water too long, and doubt any one having healthy and lively fish under such conditions. The fish deposit a large quantity of dirt which no amount of plants could possibly absorb, thus making the bottom of the aquarium foul and impure, tainting the whole of the water.

For those who have no self-acting syphon, obtain a piece of india-rubber tubing about 30 in. long; use that as a syphon to draw off the dirt accumulated at the bottom; this will keep the water clean, and you need not remove or touch your fish. Mine are never removed, and I use an india-rubber syphon as well about once a fortnight. As you draw off add more water gently.

West Country.

THE HOUSEHOLD.

To Pickle Walnuts.—Make a brine of salt and water in the proportion of ¼ lb. of salt to 1 quart of water, soak the Walnuts in this for a week. Run a larding or knitting needle through them in half-a-dozen places. Put them into a sauce-pan with some of the brine, and give them a gentle boil for one or two minutes. Drain them in a cullender and lay them on a large dish tray, basket, or on some paper. Put them in the air until they turn black, throwing them about until they are dry and free from moisture. Fill the jars three parts full with Walnuts, and fill up the jar with the following pickle hot:—To each quart of the best vinegar put 1 oz. each of black peppercorns, long pepper ginger, ½ oz. of allspice, ¼ oz. of cloves, a few chilies, and salt to taste. Boil this spice and vinegar five minutes. A clove of garlic put in after the vinegar is boiled is by some thought an improvement. They will be ready in six weeks.—J. W.

Potato Salad.—Can any one give me a good receipt for making Potato salad? [Cut cold boiled Potatoes in rather thin slices; put them into a salad bowl with a teaspoonful of chopped Parsley, half a teaspoonful of Eschalots, cut very fine, two tablespoonsful of oil, two of cream, and two of vinegar; season with a little pepper and salt, and toss all carefully together without breaking the Potatoes.]

How to Pickle Eggs.—Can any one tell me the proper way to pickle Eggs?—W. Brown. [1 lb. quicklime, one handful of salt, 1 gallon boiling water. Pour into a deep jar, stir well, and let it stand till cold. Drop the eggs gently into this mixture, occasionally stirring it up; it will keep them for months.—C. P.]

—— If pickle means to preserve, the following plan I have tried and found successful: Pour boiling water on some fresh unslaked lime and add 1 lb. of common salt; make the solution strong enough to float an egg; stir occasionally, and keep the jar or tub with the eggs in a cool place all summer, and in winter they will be found quite sound and good.—J. B. K. G.

Bottling Gooseberries.—Which is the best method of doing this?—Tyro.

GARDENING
ILLUSTRATED.

VOL. II.—No 77. *SATURDAY, AUGUST* 28, 1880. PRICE ONE PENNY.
REGISTERED FOR TRANSMISSION ABROAD.

CAPE JASMINES (GARDENIAS).

In most gardens where warm greenhouses exist Gardenias are found. They are the sweetest of all flowers, and perhaps the most appreciated of any. Their odour is peculiarly rich and satisfying, combining that of the Stephanotis and the Rose. The colour of the more popular sorts is the purest white, which renders them the more valuable for bouquet and other purposes. Gardenias, however, if crushed or when about to fade change colour ; but even when thus discoloured by time or accident they retain their sweetness. On the whole, Fortune's Gardenia (G. Fortunei) is perhaps the best ; the flowers are larger than those of florida, and it also flowers more freely. The habit and constitution of the plant are also all that can be desired. It may, however, be remarked in passing that the variegated variety of florida flowers more freely than the normal type, and produces flowers almost equal in size and sweetness to G. Fortunei. There is a larger flowered variety called G. radicans major which produces flowers nearly as large, though not so finely shaped, as those of G. florida. The variegated variety of G. radicans is almost worth growing as a fine-foliaged plant, and it flowers as freely as the green-leaved or normal type. The Gardenia citriodora figured on page 311 is a plant of a character quite different from either of these, and is comparatively rare in cultivation. It is, however, very fragrant, with a strong suspicion of Orange blossom about the perfume. The flowers are also single. The old G. radicans is also a useful free-flowering variety much prized for bouquet making. G. Stanleyana is different in habit and flower from all the others, but as regards completeness it should hardly be named with them. It is a highly ornamental stove plant, with large trumpet-shaped flowers about 8 in. long and 5 in. across. Its colour is peculiar, the interior being a sort of reddish-brown approaching to crimson and margined with white. The place for this variety is the rafter, wall, or roof of a stove, as it delights in heat and moisture, being a native of Sierra Leone. The other varieties, with the exception of G. citriodora, which comes from Natal, are natives of China and Japan. The whole of them are, however, shade and heat-loving plants when in full growth ; and the best places in which to grow Gardenias in perfection are close pits or houses where an atmosphere bordering on saturation and a top and bottom heat of 65° or so can be maintained while they are making their growth and opening their flowers. Under

WELL-GROWN GARDENIA (G. INTERMEDIA). LIFE SIZE.

such favourable conditions the foliage and flowers will be almost as large again as under drier and cooler treatment.

Potting, &c.—After flowering Gardenias should be shifted into fresh pots if needful, and any pruning or training required should also be attended to. Under good culture, however, Gardenias can hardly be said to need either. Even the flowers should be gathered singly and mounted, as if cut with branches many shoots would be cut off, each of which in the natural course of things would have developed into a flower-bud. Pruning in the same way, by diminishing the number of the shoots, reduces the flowering capacities of the plants, and should be indulged in as little as possible. After the growth is completed and partially ripened, all the hardier varieties, such as florida, Fortunei, and radicans, may be placed for a few months in cold pits, or even in a sheltered position out-of-doors throughout the warmer summer months. The comparatively sudden transition of the plants from cool to warm quarters quickly develops the flower-buds, as Gardenias bear forcing well, and seldom drop their buds, unless exposed in a dry atmosphere as well as to a high temperature. At one time the belief was almost universal that manure heat was necessary to the perfect culture of Gardenias, and doubtless many fine flowers were grown in manure beds by our fathers and by some of us in our younger days. Great merit was attributed to the ammonia, not only in developing the size of the flowers, but also in filling them with fragrance; and, considering the close affinity between ammonia and some of our scents, this idea had a scientific basis to rest upon. But doubtless the chief use of the manure heat was the maintenance of a genial atmosphere around the roots and tops of the plants. Certain it is that Gardenias are now generally grown as well or better without manure heat than ever they were by its aid, and one of the best means of keeping up a constant supply of these sweet flowers is to devote a house to their cultivation and plant them out in borders.

Houses for Gardenias.—Low span-roofed houses, with heated borders on either side of a central path are, perhaps, the most handy for the wholesale culture of Gardenias, but lean-to houses also answer well. In the case of the latter, the whole of the back wall may be covered with the plants with several rows of dwarf plants in front. Houses of this sort will produce an immense quantity of flowers, for Gardenias may be forced into producing two crops in a year. They flower on or near the extremity of the young shoots, and as young shoots are produced and ripened the development of the flowers follows as a matter of course on the application of sufficient heat and moisture. Gardenias planted out also yield a long succession of bloom. The flowers being gathered at different times, the young shoots are also formed at different seasons, and large, well-established plants under liberal treatment thus get into a very useful way of semi-perpetual flowering, which enables the cultivator to gather many a welcome flower at almost any season. But of course Gardenias, by means of changes of temperature and treatment, may also be made to flower but once in a season, as is mostly the case with those cultivated in pots. Whichever mode of culture is adopted, the best soil for Gardenias is equal parts loam, leaf-mould, or thoroughly sweet and well-decomposed manure freely mixed with sharp silver sand. Many prefer peat to manure or leaf-mould, and, no doubt, Gardenias do well in loam and peat, but they do better with the manure or leaf-mould. The drainage should be ample, but not excessive, as the plants love moisture when in full growth. When the pots or borders become full of roots, few plants enjoy manure water or turn it more rapidly to good account than these. Everything, however, approaching to over-feeding or over-saturation must be avoided.

Insects.—The Gardenia has one failing, and that is, it is very attractive to mealy bug, and once this pest gets established it is difficult to eradicate. The surest means of keeping the plants clean is to mark the first bug and touch him with paraffin oil; this oil seems to kill at once. Thrips, aphides, scale, &c., are the result of errors of cultivation mostly, and will not occur under the above treatment. Soap may, and paraffin or a touch of turpentine will, clear them off at a single dressing.

Propagating.—Few plants are more easily propagated than Gardenias. Small pieces of the young ripe wood, inserted in silver sand, either under or without bell-glasses, in a sharp bottom-heat of 80° and a moist atmosphere, root readily. When rooted, pot off singly, and grow in a warm moist temperature, stopping the shoots occasionally to induce the plants to grow bushily.

Gathering the Blooms.—The blooms of the Gardenia are easily damaged by careless gathering or rough handling, and every bruise will show before many hours are over. The flowers should always be mounted with their own leaves; the larger kinds of Myrtles form the next best setting.

Gardenias for Market.—The blooms of few plants are more valued in the market in a cut state than those of the Gardenia, and although they do not now realise such high prices as formerly, on account of the increased competition and the large numbers grown, yet good prices are often made. Mr. Ladds, of Bexley, has a house 200 ft. long and 30 ft. wide entirely devoted to their culture. The plants are permanently planted out on mounds of earth 1 ft. or so higher than the floor of the house, with the view of preventing the roots from becoming sodden through the continual heavy syringings to which the foliage is necessarily subjected in order to keep it in a healthy growing state and free from insects. The bulk of the plants are from 6 ft. to 7 ft. in height, and as much in width; they start into growth early in the year, and, from February, all through the summer, they yield a profusion of large flowers. Previous to commencing to force, the plants receive a thorough dusting overhead with a mixture of soot and guano in order to clear them of mealy bug, a pest to which Gardenias are especially subject. In that state they are allowed to remain for a few days, when the mixture is washed off the foliage by means of a powerful syringe. This treatment eradicates all insects, and, owing to forcible and frequent syringings, they are never again able to gain a footing, until the plants come fully into bloom, and syringing is necessarily discontinued. Indeed, the blooms are generally all gathered before insects of any kind can do any very serious injury to them. The guano and soot, when washed off the foliage, serve to stimulate the roots, and induce a free and healthy growth, and although the leaves are sometimes slightly burnt by the mixture, yet it does not apparently injure the constitution of the plants. Some growers, on the other hand, cultivate them in 10-in. and 12-in. pots. They are allowed to grow from 3 ft. to 4 ft. high, and from 2 ft. to 3 ft. through at the base, and in April large houses full of such plants, well furnished with deep green glossy foliage, and loaded with fragrant, wax-like blossoms and buds, are seen in the best market gardens. Some prefer growing Gardenias in pots on account of their being more easily cleared of insects than when permanently planted out, and, moreover, they can be moved from place to place, or disposed of when it becomes necessary to do so. The plants grown in 6-in. pots for market are struck from cuttings inserted thickly in pots during spring, summer, and autumn; these are plunged in bottom-heat in a warm, moist atmosphere. After the cuttings have taken root they are potted off singly into 4-in. pots, and eventually shifted into 6-in. ones, in which size they are allowed to flower. Plants from which the blooms are gathered are cut back, placed in a moist heat, and in a few weeks they break up from the bottom, and soon afterwards furnish another crop of flowers. Gardenias grown in pots, it is said, produce better formed blooms than those planted out, and, moreover, they can be conveniently removed from place to place as required, and a few can be got into flower at a time, as becomes necessary. Cut blooms of Gardenias fetch from 10s. to 15s. per dozen when perfect in shape and colour. Plants in 6-in. pots, bearing from eight to twelve flowers, fetch from 15s. to 30s. per dozen. The best kind grown by market gardeners is G. intermedia; and G. radicans is is also cultivated to some extent.

The engraving which we publish this week on our front page is from a specimen grown by Messrs. John Standish & Co., of the Royal Nurseries, Ascot, who pay great attention to the cultivation of the Gardenia in their establishment. The flower in question, one of thousands of a similar size, was from a young plant of the variety intermedia, which was not more than nine or twelve months old from the cutting. To ensure flowers of the quality and size, it is absolutely necessary that the plants should be perfectly clean and free from mealy bug from the first formation of the plant. The compost used by Messrs. Standish is the best fibrous peat with a good admixture of silver sand. Clay's Fertiliser is plentifully used in the compost. The plants are grown in a brisk heat of about 65° or 70° at night with a rise of 20° in the daytime (with sun-heat), with abundance of water and moisture, and are placed as close as possible to the glass. When the plants are well established in their flowering pots, which are 10 in. or 12 in. in diameter, they are supplied liberally with guano and soot in the watering.

Wasps, Mice, &c., amongst Ripe Fruit.—In some situations insects, birds, and small animals do a good deal of mishief amongst ripe fruits. Birds, of course, may be kept off by nets, and a covering of hexagon netting will keep off wasps, but the netting is expensive if a large extent of wall has to be covered. Somehow, too, I always think that fruit covered up during the finishing stage of ripening is not so good in flavour or colour as when fully exposed. Where close netting cannot be had for covering choice wall fruits, such as Peaches and Nectarines, to preserve them from wasps at this season, it is a good plan to hang up bottles half filled with some sweet liquid, such as honey and beer. These should be hung up the moment the first wasp makes its appearance, for if delayed, the wasps will attack the fruit, and the probabilities are that they will continue to feast upon it, whilst if the decoy bottles had been at hand, they would have been tempted to enter, and so have found death in the bottle. Scott's wasp destroyer is also a capital remedy for them. Where mice are numerous they are often exceedingly troublesome in Vineries in which ripe Grapes are hanging. They run up the Vines and nibble the berries mostly at the top of the bunches, and soon do a large amount of mischief. The remarks just made in reference to wasps are applicable in even a greater degree to mice, for, if they once begin upon the Grapes, traps and poison will have to be baited with something tempting before they will look at them; if, however, a trap or two be kept constantly set about the houses and sheds, when a hungry mouse comes in he enters the trap and is caught before a lodgment of any number can be effected. I have at various times had a good deal of trouble with mice, and I find there is no better plan than keeping two or tree traps set in different places about the premises. There is an advantage, too, in having traps of different kinds, for mice have their peculiarities. I

have often found, when they have fought shy of the old brick traps, that by substituting Pullenger's patent or one of the ordinary forms of spring wire traps with a change of bait, that they might be captured. As regards the destruction of wasps, if they are at all troublesome the nest should be hunted up and destroyed. The old-fashioned plan—and it is still as good as any—was to mix some common gunpowder with about a fourth of its bulk of sulphur; moisten it with water so as to form a thick, paste-like putty; form it into small rolls or squibs about 3 in. long by ½ in. in diameter. These, when wrapped in paper, ignited at one end, and dropped into the hole leading to the nest, give off such a thick suffocating smother, as to render the wasps insensible, when the nests should be dug up and the whole destroyed. A little practice will enable any one to destroy wasps effectually in this way, and it is just the kind of work in which boys delight, and for which a little extra pay might be given. Another plan that might be tried in some cases is to pour gas tar down the hole. This blocks up the entrance, and the fumes from the tar smother them. It sometimes, however, fails, through the nest being at some distance from the entrance and the wasps opening another outlet.—H.

VEGETABLES.

The Schoolmaster Potato.—I have just dug up my Schoolmaster Potatoes. From half a peck (7 lb.) I have netted 108 lb., making fifteen and a half fold increase.—J. M.

Showing and Storing Potatoes.—Mr. Peter M'Kinlay, the well-known grower and exhibitor of Potatoes, stores his best samples in a large, airy out-building, lined with tiers of small wooden bins ranged one above the other, but open at the top, each one holding about half a bushel of Potatoes. Covered up with dry sawdust, they remain clean and fresh until required for table. The bins are subsequently used for storing the various sorts for seed.

Potatoes on Refuse Heaps.—Two years ago I cleaned out a pond in which the small stream flowing through it had left a large quantity of alluvial deposit. This was shot into a meadow close at hand, and formed a heap about 14 rods in area. This I planted in spring with Irish Rock Potatoes, 3 ft. apart every way. The crop which we raised last week quite realised my expectations, eight bags (160 lb.) of prime tubers coming to the scale. It is worthy of remark that they were almost entirely free from disease, while Potatoes in the kitchen garden adjacent were much affected by it. Might not many of the waste heaps which we constantly see about the country be thus advantageously utilised?—W. J. F., *Somerset*.

Late-sown Endive.—This is a good time to sow the latest crop of Endive, which should be done on a border with a good slope, so as to ensure drainage. If sown in drills 1 ft. apart and thinned just sufficient to keep the plants clear of each other, they will not get large, but will be more likely to withstand severe weather than large transplanted crops from early sowings. As they keep growing slowly in the winter, they prove serviceable during the earliest months of the year, when materials for mixed salads are in great request; the Green-curled and Batavian stand the winter better than the Moss-curled varieties.

Curled Chervil.—This useful herb is often in request for culinary purposes, and for mixing with salads, &c. It is of very easy culture, and a small bed of it will supply a large household. During the greater part of the year it may be obtained from the open air by sowing a few rows across a border at intervals of a month. To meet the demand, however, in exceptionally severe weather, a few boxes of it should be sown now, and when well established out-of-doors they may be removed to pits or houses for a mid-winter and early spring supply; for, in addition to other uses to which it may be put, it is preferred to Parsley for garnishing.

Pricking out Cauliflowers.—As soon as the young plants are large enough to handle they should be pricked out in cold pits or frames about 3 in. apart each way in good soil. They should be kept as fully exposed as possible during genial weather, but covered during severe frosts, for although hardy enough to stand several degrees, checks to the growth, either from excessive drought or cold, are the conditions most likely to induce premature hearting; therefore avoid all extremes.

Mushroom Beds.—The best season for making up these is now at hand, and when a good supply of fresh stable manure is at command it should be carefully shaken over, and any dry portions thoroughly moistened, adding a good quantity of fresh turfy loam as the work progresses. The loam will moderate the heat and make the bed last longer than it otherwise would do, as the violent heating to which the manure is sometimes exposed drives off the elements most essential for the growth of the Mushrooms, and hastens the decay of the manure, thus necessarily shortening the season of production. Beds made up firmly of this mixture seldom heat too strongly, and they may be spawned almost immediately. As soon as the spawn begins to run a good coating of new loamy soil, of a rather adhesive texture, should be sifted fine and applied as a covering, beating it down as firmly as the back of a spade can make it. Beds made in this manner in situations where a moist intermediate temperature can be commanded have continued to supply abundance of Mushrooms for a long period.—J. M.

New Potatoes in Autumn.—Why should we not have new Potatoes in autumn? I have tried the experiment this season, and am quite satisfied with the results. The variety planted was Myatt's Early Ashleaf. In spring I kept rubbing the buds off a limited number of tubers, which were also retarded as much as possible by being kept in a cool place and laid out singly. The buds were rubbed off them up to within a short time of planting, when they were allowed to grow to from 1 in. to 2 in. in length. The planting was done early in June, on the same border from which the early crop was taken. It was in no way prepared, beyond adding a little leaf-mould on which to lay the seed when the drills were drawn. Potatoes, I have always observed, turn out white and clean when there is a slight layer of leaf mould placed under and above them. The drills were drawn in an oblique direction, as the border is a south one, and thus the side of the drill was fully exposed to the warmth of the sun. The crop is now becoming fit for use, and promises to be in every respect satisfactory. The haulm is of course weak, consequent on the shoots being rubbed away so often, but the tubers are a fair size, well formed, and of excellent quality. They will not be ready for lifting for some time yet, and when they are a portion will be laid in sand, where they will keep clean and fresh for a further period. By making one or two plantings from the beginning of June to July a succession of young Potatoes might be kept up to Christmas.—W. H.

FRUIT.

Figs in the Open Air.—I have lately gathered from open walls some of the finest Figs I ever saw, and from a position, too, where we could not get other fruit trees to succeed. The wall in question looks full south. We dug deep pits within 3 ft. of its base in space which is used as a footpath and gravelled, and consequently the soil over the Fig roots is very hard. Thus circumstanced, the trees make short, well-ripened wood, and the heat reflected from some glass pits built in front of the wall ripens the fruit from three weeks to a month earlier than in more open positions. This wall is never too hot for Figs, and we have some with even more restricted root-room that bear good crops if well soaked with water when the fruit is swelling, for if allowed to suffer from want of moisture, it is apt to drop prematurely. Figs should, therefore, be mulched over the roots, and a few thorough good waterings should be given them when they are in full growth. The pruning and training adopted is of the simplest kind; in short, we only stop those shoots in summer that are getting bare at the base, and remove them entirely in the following spring. Figs must on no account be trained too thickly, as the foliage, which is large, must be fully exposed to light. I allow the current year's growths to grow away from the wall, as by nailing them in closely the embryo Figs are encouraged to swell, an occurrence which must be by all means avoided. As a protection from frost the easiest method is to unnail all the shoots and lay them down by the base of the wall, where they should be covered with Fern, Spruce branches, &c. In spring what pruning they require may be given them and the branches firmly secured by strong ties at the proper distance apart, keeping up an equal distribution of young bearing wood from base to top. Fancy modes of training are not applicable to Fig culture. As regards sorts, the Brown Turkey is both trustworthy and prolific; the White Marseilles is the finest kind, but it is not nearly so prolific. Positions suitable for Figs occur everywhere, for their foliage is as handsome as that of many climbing plants, and the attention which they require is about the least needed by any kind of fruit tree, while the chances of a crop are all in their favour, as they are late in starting into growth, and consequently avoid that greatest of all drawbacks to hardy fruit culture—inclement springs. A hot, dry summer, which is so disastrous to so many other kinds of crops, will give us, with a minimum of labour, an abundance of luscious Figs in autumn.—J. G., *Suffolk*.

Gooseberries and Currants as Espaliers.—I saw a neat and excellent way of growing Gooseberries and Currants the other day. The kitchen garden is divided into the usual compartments, and at the margin of each quarter, running parallel with the walks, are small posts fixed several feet apart and about 3 ft. high; to these are strained three lines of stout iron wire, openings being only left at the corners, sufficiently large to allow a wheelbarrow to pass. The Gooseberries and Currants are planted 18 in. asunder, and three rods are carefully trained up the wires about 6 in. apart. These have reached the top of the trellis long ago, and are pruned on the close-spur system. Thus planted, they form an unbroken line from end to end, and present a very neat appearance, especially when loaded with fruit. Prominent among the Gooseberries were the Warrington and the old-fashioned small Rough Red. Gooseberries and Currants managed in this way occupy no more space than a row of Parsley; the fruit can be gathered without having to step off the walks, and an ordinary length of netting dropped loosely over the top, touching the ground on both sides, acts as a thorough protection from birds. The trees in question have been planted about sixteen years, and judging from appearances they will keep in good condition for many years to come.—H. H.

Pruning Peach Trees.—As soon as the fruit is gathered, all the small shoots should be unnailed, and all the wood which has borne fruit cut back to the point whence the young wood starts; unless there are vacancies to fill up, there is no occasion to wait for the falling of the leaves to do this, as I believe the sooner this is done in autumn the better the young wood will ripen; but shortening of the young wood had better be delayed till February for two reasons: First, because after the buds have swelled a little there will be no difficulty in distinguishing the flower-buds from those that produce wood only, and it is important to cut each shoot back to a wood-bud, as without a leader the fruit, even if it set, will be flavourless; and secondly, leaving the shortening till the buds are pushing, and leaving the tree unnailed till the last moment, has a tendency to retard its flowering, and a few days' delay in the case of severe weather sometimes saves the crop. The young wood should be cut back one-third, one-half, or two-thirds, according to its strength and firmness; always cut back to well-ripened wood.

Rust on Grapes.—Having seen in GARDENING that a correspondent attributes the cause of rust on Grapes to the thinning scissors, I thought it might prove of benefit to the readers of GARDENING to give the experiment I tried on several occasions a few years ago when I was in the Vineries at Welbeck, where Grapes are grown in abundance. My opinion is that rust on Grapes is caused by the hair of the head coming in contact with the berries when thinning. I tried several bunches, and found every bunch I let my hair touch turned rusty, and I do not think there is any other cause. I have since tried the same experiment, and always with the same results.—E. WHITING.

Choice of Apples.—I think any notes on this matter may be interesting to many of your readers, as they are to me, and I hope others will give their experience on the subject. Among twenty or more kinds, the only two which gave me a satisfactory crop this year are Duchess of Oldenburg and Small's Admirable. Keswick Codlin has a great number of Apples, but they are small and almost worthless this year. The Duchess has borne well each year since it came into bearing, and so also has Small's Admirable, but I do not rate its quality so high as some do. Alluvial soil in the east of England.—A. B. G.

AUTUMNAL-FLOWERING STOCKS.

This is a race of Stocks of a very useful character, and it is doubtful if their qualities are so well known as they deserve to be. They are termed autumnal Stocks because they flower later in the summer than the ordinary Ten-week, though like it they are annuals. When looking over Messrs. Sutton's seed grounds at Reading a few days ago I saw there autumnal Stocks growing under several names, such as the Cape, Emperor, Imperial, and East Lothian, besides others. They are particularly valuable, inasmuch as they prolong the blooming season of Stocks, and if the Intermediates are grown in pots for spring flowering they commence the floral season, which, taken up by the Queens and Bromptons, is carried on by the German Ten-week, and finished by the autumn-flowering varieties. By a little judicious management a garden may possess Stocks in bloom from April till November, or, it might be said, nine months in the year.

The autumn Stocks are remarkable for their free branching growth. The plants throw out a large number of side branches, each producing a spike of flowers, and one plant will furnish a large number of spikes. The bloom is put forth successionally, and an individual plant will bear many more flowers than one of the large-flowered kinds. Advantage was taken of the several types of Ten-week Stocks growing together to compare them, and it was difficult to say wherein the Cape Stocks differed from the autumnal and the others named above. They appeared to be all of one type, but with differences as regards precocity or backwardness, or of quality and size in the flowers. But that the type under whatever name it may be known is a very useful one there can be no doubt. In Scotland the East Lothian Intermediate Stocks are now extensively grown. Our English Intermediate Stocks are sown in July and August, and wintered in cold frames to bloom in spring. In Scotland the East Lothian Stocks, which are exactly of the character of the autumn-flowering type, are sown about the end of March in a frame or under hand-glasses, and when large enough are transplanted to the border or beds where they are to bloom. This is done about the middle of May, when the plants are 2 in. or 3 in. high, and transplant well. Throughout August, September, and October they flower freely and very finely if the strain is good, and when the autumn is fine and dry they will continue in flower till November.

The culture of these Stocks can be strongly recommended for cutting purposes. They produce side shoots in such abundance that cutting can be carried on unsparingly. Of the types at Reading preference is given to the East Lothian; and their superiority in the matter of size, brilliancy, and distinctness, as regards colours and the fullness of the flowers, can no doubt be accounted for from the fact that Scotch growers have well selected their strains, and greatly improved them in doing so. Seed of a good Scotch strain is dear, but the grower will be certain to have fine double flowers, and the free branching habit of the plants makes it necessary that they should be planted farther apart than the ordinary Ten-week. One best realises the beauty of Stocks when they are grown in masses. This is what our Scotch friends do to perfection; grouping Stocks is with them an essential part of flower gardening, and they are enabled to work out charming pictures that command admiration from all who see them.

R.

Rice-paper Plant (Aralia papyrifera).—This plant, of which the annexed engraving is an illustration, is one which has of late years been much employed in what is termed subtropical gardening. In northern counties it can only be put out-of-doors from May till October, but in the south it is almost hardy. Anyone having an unheated house might grow it with advantage, for it could be put out during the summer, and would help to decorate the greenhouse during the winter. This Aralia is chiefly propagated by means of its fleshy roots, which are formed at the base of the stem. When the plants are taken up in autumn these roots are taken off and cut into 1-in. lengths, and placed in pans of light soil about ½ in. below the surface. The pans are then placed on the shelf of a greenhouse, or in a frame close to the glass, in a temperature of about 80°. In due time these roots throw out shoots, which are potted on, and when well established they are removed to a cooler temperature, and finally hardened off ready for planting out-of-doors.

Rice-paper Plant (Aralia papyrifera); hardy in the south of England.

Alstrœmerias.—In soils and situations where Alstrœmerias are found to succeed, a more useful or showy class of plants cannot be had, their large, Lily-like heads of bloom being exceedingly useful for cutting, as well as particularly showy and attractive. In order to get them to do well, however, the soil in which they are to be planted should be deeply trenched or stirred, and if at all stiff, or of a wet, retentive nature, it should have plenty of leaf-soil and sand worked into it, the tuberous roots of Alstrœmerias, when lying dormant in winter, being readily injured by stagnant moisture, which soon brings on decay. To prevent this, the best way is to prepare the bed for them at starting by thorough drainage, as it is an operation that pays well for the labour bestowed on it, Alstrœmerias being plants that when once fairly established will last a lifetime without much care or attention. A narrow, south border along the front of a greenhouse or other similar position is the best situation for them, as there they get the protection of the wall, and from the slight warmth maintained inside are not subjected so much to the action of frost as they would be elsewhere. Being naturally deep-rooting plants, the drainage should be placed at least 2 ft. beneath the surface, and have some rough material, such as half-decomposed manure or fresh-cut turf, laid on the top to insure the interstices being kept free and open. This done, the filling in and planting may be carried out either now or at any time between August and May; but the best season is after winter is over, as then there is no risk from frost or wet, and the plants soon start away and become established. A good way in which to manage Alstrœmerias is to sow the seed where they are to remain, as of all herbaceous subjects they are the most difficult to transplant, an operation that can only be successfully performed by trenching the tubers out just as growth commences, and if they are then carefully handled, so as not to bruise or break them, most of the more fleshy portions will be found to grow. In the case of seed sowing, drills of about 1 in. deep should be drawn, in rows 1 ft. or so apart, in which, when the plants come up, they should be allowed the same distance asunder. They will soon furnish the bed or border, and make a grand display. To protect them from frost during severe weather, a slight mulching of some kind is necessary, and nothing answers the purpose better than half-decomposed leaf-soil, which is a capital non-conductor, and as neat-looking as anything that can be used.

The Spotted-leaved Arum (Richardia albo-maculata).—Grown in groups in deep, rich soil, this plant produces a fine effect. It should be planted early in spring, and, if in a light, sunny position, its leaves will become large and finely spotted, and from good roots flowers will be produced freely. After the leaves have died down in autumn the roots should be lifted and stored in sand or dry soil in a shed or cellar. If wanted for pots a few roots may be started when required; they force well and make excellent window plants. Market growers are paying attention to its culture, and it will soon be as plentiful as the green-leaved form.

Triteleia laxa.—I would specially recommend this plant for the herbaceous border. It is a most beautiful plant resembling, when in bloom an African Lily (Agapanthus) in miniature, but with flowers of a deeper richer shade, being of a fine Tyrian purple. The present is a good time to get bulbs of this plant, which should be planted in deep loamy soil, and have some sand scattered on and around them to preserve them from excess of wet while lying dormant during winter.—S.

Prolonging the Blooming of Sweet Peas.—When Sweet Peas are getting rather past their best they should be cut down level with the tops of the sticks, and renewed growth will be the result. From the bottom to the top a new growth will spring up, and there will be an abundance of bloom until the end of October. All seed pods should be kept clipped off unless seed be wanted, and if a good soaking of manure water be given when the plants commence to make fresh growth it will do much good.

How to Raise Verbena venosa.—Since the ordinary varieties of Verbena have almost disappeared from flower gardens the peculiar colour afforded by this sort (a bluish-violet) has been more than ever valuable, not only for furnishing whole beds with that particular shade, but more especially from the good effect produced by it in mixed beds, as, for instance, associated with variegated-leaved Pelargoniums, such as P. Manglesi, &c. Its wiry, upright habit of growth, not exceeding 18 in. in height, renders it a suitable plant for many combinations. It will survive the winter out-of-doors in dry, warm soils, and if lifted and placed in a warm house or frame abundance of cuttings may be procured in spring that will strike freely. If, however, a large quantity of good, hardy, bushy plants be required, the best plan is to procure seed of it and sow it in shallow boxes in autumn, and by keeping the seedlings in a cool house or pit during winter, dwarf, bushy plants in abundance may be secured by May.—G.

The Cardinal-flower Lobelia (L. fulgens) **in Towns.**—This, as a pot plant, may be well flowered in London. I purchased some plants in May in 2½-in. pots. Instead of transplanting into larger pots, as I had done before when I failed to flower them, I placed the pots in 5-in. ones, and packed the space between with Cocoa-nut fibre. The experiment succeeded well, and every plant so treated has flowered. Many plants do well when treated in the same manner. Little root room, if only the roots can be kept moist and protected from extreme heat and cold, seems to be favourable to the formation of flowers.—L. B.

Bouquet or Pompone Dahlias.—During these last few years this section of the Dahlia family has become very popular; the blooms being small and compact, resembling a Ranunculus more than those of a Dahlia, makes them much more serviceable in cut-flower decoration than those of ordinary border Dahlias. I have also found them most effective as a background in mixed borders or for large beds. The roots, left in the open ground all winter, are quite safe if a good coating of coal-ashes be put over them when the tops are cut down. If lifted for purposes of propagation they may be safely stored in any cool shed secure from frost, and if covered with any partially dry material, such as old tan, Cocoa-nut fibre, or leaf-mould, they will start more strongly into growth than if over-dried by exposure to the atmosphere. At this season the flowers are especially useful in floral decorations of a large character, where delicate or fragile blossoms are not nearly so effective; and the Dahlia, moreover, will last in a perfectly fresh condition for some length of time, even without inserting its stalks in water—a great gain where, as in the case of harvest festivals, school treats, &c., the decorations have to be extemporised without having recourse to the best preservatives. I have found the following varieties all that could be desired, viz., Angel of Peace, Bessie, Bijou, Crimson Beauty, Fireball, floribunda, Glowworm, Golden Canary, Jubilee, Little Bobby, Little Darling, Little Dear, Little Helen, Little Nigger, Little Snowball, Pearl of Lilliputs, Prince of Wales, Pure Love, Sacramento, Sappho, Seraph, Sunshine, Tomtit, and Voltaire.—G. R.

Chrysanthemum Burridgeanum.—This beautiful hardy annual, which is now in full flower in some gardens, bas been some years in cultivation. It was raised from seeds of C. tricolor by Mr. Burridge, a seed grower in Suffolk, after whom it has been named. The parent species or type, C. tricolor, or C. carinatum, as it is often called, is a native of Barbary, whence it was introduced about 1796, and has since been grown as a distinct and effective autumn-flowering plant. The improved variety, as shown by our illustration, is a compact and bushy-habited plant, and bears large golden-yellow flowers, each having a dark purplish-brown zone and a purple eye or disc, the colours being very bright and well defined. It is best propagated from seeds sown towards the end of May in open beds or borders where the plants are to flower, or they may be sown earlier in pans or boxes of light, rich earth, in a pit or frame, from which they can be transplanted after all danger from frost is over. Planted singly in rich soil in an open and sunny position, it forms one of the most beautiful of all composite-flowered annuals, and well deserves culture. It generally blooms in August, and lasts fully three months in beauty, or until cut down by frost.—B.

Antirrhinums as Annuals.—Many who treat the Antirrhinum as a biennial have had to deplore the loss, through the severity of last winter, of many a promising plantation, hopelessly killed root and branch. This calamity has occurred two years in succession; hard frosts following a wet autumn appear to be most destructive to Antirrhinums. I saw in a nursery a few days ago some large beds in full bloom of very fine Antirrhinums, all of which had been raised from seed sown in heat in January and February last; the young plants had been grown on into size as fast as possible and then planted out in the open ground. This is not a new, though it is an uncommon, practice, and the great advantage derived from it is, that it makes one independent of the severity of the winter. The plants in bloom were of large size, and were producing large spikes of very fine flowers, some of the striped varieties being of great beauty. The Tom Thumb varieties, also sown at the same time, are very attractive, and well suited for small gardens.—D.

Echeveria secunda glauca.—This pretty little succulent, so highly valued on account of its neat, compact habit and the glaucous hue of its foliage for bedding-out purposes, is equally valuable as a flowering plant. Those who carefully pick off each flower-stem as it appears are probably little aware that by so doing they are depriving themselves of half the pleasure that this plant is capable of affording. A well-developed plant will throw up half-a-dozen flower-stems, which, being of a bright coral-red, and bearing a profusion of orange-red wax-like flowers, offer a pleasing contrast to the glaucous tint of the foliage. The blooming period is a long one, lasting from the middle of May to the end of August, the flowers, owing to their great substance, possessing the ability of withstanding any amount of wet weather.—C. B.

ROSES.

Pruning Marechal Niel Rose.—Considerable diversity of opinion has been expressed from time to time as to the best method of growing this Rose, some asserting that it does best on its own roots, others being equally sanguine that it succeeds most satisfactorily on the seedling Brier or some other stock. Leaving these differences out of the question for the present, permit me to allude to another peculiarity in the cultivation of Maréchal Niel, and that is the time at which it should be pruned, and also how that operation ought to be performed. When in a semi-dormant state this Rose dislikes much knife work. Several examples of it planted out here two years ago, and which were unusually strong (one having made a main rod from 25 ft. to 30 ft. long last year) got infested with green fly, and in fumigating it some of the more tender leaves got injured through the Tobacco smoke. This was when the buds were about half developed last spring, and, of course, wherever the leaves were most injured the flowers suffered in proportion. After flowering, I decided on heading back some of the plants with a view to strengthening them when they began to push. I find, however, that the rods that are strongest at the base are the weakest in pushing, and one or two of the plants are so weak that they will have to be replaced; other plants of moderate growth have pushed vigorous shoots from their base. It is hard to get over facts like these, which point directly to the Rose doing best on its own roots. Had our plants been worked on the Brier or any other stock, the probability is that most of them would have died, whereas every succeeding shoot that is produced from the base is a degree stronger than its predecessor, and tends to increase and invigorate the roots. I would recommend, therefore, that all pruning, or rather thinning out, necessary in the case of this Rose should be done when the plants are in full growth, and not before they start after flowering. The strongest shoots should be selected, and the weaker ones rubbed off with the fingers at an early stage of their growth, and if further thinning be necessary it should be done before the season of growth is very far advanced. It is so easy to propagate a few fresh plants every season that those who desire to cultivate this Rose by the simplest method should be prepared for the loss of an old plant from time to time by having young ones ready to take its place.—W., *Liverpool.*

Tricolor-flowered Chrysanthemum (C. Burridgeanum).

Rose Souvenir de la Malmaison.—Few Roses are more effective just now than this, all the strong shoots of which are crowned with lovely bunches of the most delicate flesh-coloured blossoms. Beds of this kind, in which Tritomas and other autumn flowers have been planted, have a fine effect at this season of the year.—J.

House and Window Gardening.

HINTS ON WINDOW PLANTS.

Pots 6 in. in diameter are large enough for most window plants, and some would require pots of less size. For various reasons it is a bad practice to use pots a second time till they have been well cleaned out. All potting should as far as possible be done by the end of August. It gives time for the plant to get well established before the short days of winter. If the importance of this were more generally recognised, there would be fewer deaths among window plants in winter. Late potting, accompanied, perhaps, by a too free use of the watering pot, causes soft, sappy growth at a time when maturation should be the first consideration. As a rule, when the days shorten less water will be required, but even then, whenever it is necessary to water at all, enough should be given to moisten all the soil, only it will be required much less frequently. These strictures upon late potting do not refer to bulbs. September is time enough for Hyacinths, Tulips, Crocuses, &c., as their natural period of growth is in the winter. Plant culture in rooms requires constant watchfulness; cleanliness is as important for the health of plants as for human beings. If the leaves be coated with dust, or the young growths infested with green fly, it is a sure sign of neglect on the part of the cultivator; the sponge should be used as often as convenient to remove dust from the leaves, and advantage should be taken of every warm shower to place the plants outside for a few hours.

If a strict watch be kept, the green fly, when it makes its appearance, may be easily kept down by picking them off without resorting to other remedial measures, which are all more or less troublesome to apply. The object should be to keep the plants clean and healthy, and by giving plenty of ventilation on all favourable occasions to make the growth hardy and strong. The ventilation of rooms where plants are growing is well worth some study, especially as I believe the more perfectly that is done the better will be not only the health of the plants, but also of the human occupants. In cold weather ventilate, if at all, only at the top of the window. Never allow a cold, keen blast from the east or north to blow through them, chilling their sap and almost shrivelling up their foliage. Be particular to open the windows early in the morning when the weather is favourable; and on warm sunny days, especially in early spring, a free ventilation will be beneficial to give colour and strength to the young growth.

In spite of all the care taken to insure strong, healthy growth, should insects attack them in large numbers, they must be destroyed, or they will ruin all hopes of obtaining good blooms. This may be effected either by fumigation or by washing with an insecticide. A friend of mine, whose windows were the admiration of all who saw them, made a wire frame and covered it with oiled calico; and whenever he saw any flies on his plants he moved them to the back kitchen table, placed his calico cover

over them, and introduced a small iron plate on which a red-hot coal or two had been placed, with sufficient Tobacco placed on the coals to fill the calico cover full of smoke, which very effectually destroyed the insects; the Tobacco, however, must never be allowed to flare or blaze, or the tender foliage of some plants will suffer. A very useful dip may be made by dissolving 2 oz. of soft soap in a gallon of soft water; then place 1 oz. of Tobacco in a basin or other vessel, and pour over it 1 quart of boiling water; when the strength has been extracted from the Tobacco, the liquid may be passed through a strainer and mixed with the soap and water. The plants should be taken one at a time and their heads dipped in the mixture, taking care that none of it gets into the pots. After dipping lay them on their sides for a few minutes, and before the solution dries on them rinse them in clean water. Either of these methods will effectually destroy the insects without injuring the plants; but, as I have previously stated, never allow the plants to suffer from want of water; pay special attention to ventilation, taking advantage of warm showers to place them outside for an hour or two, and keep a watchful eye for the appearance of the first fly, and destroy it before there is time to found a colony of them. H. E.

A Pretty Table Ornament.—Few persons know what a simple and truly exquisite ornament for the centre of the table can be had by those who are fortunate enough to procure some common white Water Lilies, which are, I think, the greatest gems of our wild flowers. Get a large full-blown flower and put it in a shallow dish or soup plate filled with water, and arrange some of the dark green leaves all round the plate; then put the Lily in the middle; with a few more leaves and place one or two half-open buds here and there, and you have your centrepiece complete, and one which everyone will admire. The natural growth of the Water Lily makes it a useful and valuable subject for arrangement, as suggested, because when thus settled we see it as it is found in its native home, and therefore has no artificial look about it.—W. A. G.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

August 30.—Sowing Radishes, also Lobelias in pots for winter blooming; potting off and plunging in bottom-heat Neapolitan Violets; shifting the few remaining spring-struck scented-leaved Pelargoniums into 6-in. pots; potting up cuttings of double Wallflowers; potting off Hollyhocks, also Brompton Stocks for planting in spring, and young Callas; shifting Primulas into their flowering pots; shifting some seedling Cinerarias into their flowering pots; putting in cuttings of Gazanias, also of Alyssum, Oxalis, Centaurea, Petunia, Tropæolum, and Agathea; planting Endive beneath hedges, also more July sown Coleworts; getting off all Strawberry runners in pots, and placing them ready for planting; putting stakes to tree Mignonette; tying Chrysanthemums; washing Orange trees for scale; digging land for Cabbage Lettuce; beginning to stub up useless fruit trees, and prepare ground for others; going over trees again in order to remove breastwood; thinning latest Turnips; hoeing and thinning winter Spinach.

August 31.—Potting off autumn-struck Coleus, Pelargoniums, and latest-sown Cinerarias; planting some young Cucumbers in large pots; beginning to plant Strawberry runners; tying up Endive to blanch; washing Camellias; cutting Lavender; pulling up Marjoram for drying, also spring-sown Onions; getting land dug for August-sown Lettuce; stopping growing shoots on Vines.

Sept. 1.—Arranging conservatory, and introducing to it Celosias, Maize, late Fuchsias, Pelargoniums, Coleus Verschaffelti and Duchess of Edinburgh, Cannas, Caladiums, Centaureas, Wigandias, and Palms; putting in cuttings of Heliotropes, Verbenas, and Antennaria tomentosa; pricking out young Pinks; staking and tying various hard-wooded plants; manuring Pea land for Strawberry plantation.

Sept. 2.—Sowing Mignonette in pots, Radishes, and Mustard and Cress regularly; shifting Gesneras into their flowering-pots; shaking out Pelargoniums and repotting them in smaller pots; shifting the latest-sown Balsams, also the latest-struck Fuchsias and latest-sown Primulas into their flowering-pots; putting in some Hydrangea cuttings; planting All-the-year-round Lettuce; gathering orchard Apples, also some Beurré Benoit and autumn Bergamot Pears; budding the last of the Briers; top-dressing Roses with horse manure and loam.

Sept. 3.—Sowing a little more Spinach to come in useful in spring; potting layered Anne Boleyn Pinks; shifting hardy Rhododendrons into larger pots; putting Salvia and Ageratum cuttings out-of-doors; putting Daturas where they could receive full sun to ripen their wood; planting Violets in frame; syringing out-door Peaches every evening to keep down spider; salting walks to keep down weeds.

Sept. 4.—Sowing Centaureas and Radishes to come in in October; potting young Czar Violets, and putting Calceolarias into pit; also potting layered Carnations; shifting some Ghent Azaleas into larger pots; putting half the orchard-house trees out-of-doors; inserting cuttings of Coleus and of variegated Sedum; planting Tennis Ball and Bath Cos Lettuce, also Sweet Williams; tying up straggling shoots of Irish Yews, staking Mignonette; bunching up Basil and placing it in a cool, airy place to dry; netting Plums; exposing Tomatoes to direct sunlight; making some beds ready for Winter Lettuce by spreading manure on undug ground, and throwing soil from the alleys over it, a method which answers well; stopping Tomatoes.

Flower Garden.

Walks must be rolled frequently, edgings cut at least once a fortnight, and lawns kept short and trim. This is the season in which to propagate Pelargoniums; but if, for want of cuttings, this cannot be done, provision should be made for wintering the old plants and propagating in the spring. A few store pots of cuttings of each of the following should be got in as soon as possible now: Coleus, Iresines, Alternantheras, Heliotropes, Verbenas, Petunias, Ageratums, Lobelias, and all plants of a similar character. Violas and Calceolarias need not yet be propagated, as they strike well in cold frames if put in any time before the middle of October. In mixed borders the first opportunity should be taken to stake Phloxes, Potentillas, Chrysanthemums, &c., and any vacant spots may be utilised for sowing a few hardy annuals, such as Limnanthes Douglasi, Collinsia bicolor, Saponaria calabrica, Silene pendula, Nemophila atomaria, and Candytufts, all of which are perfectly hardy, and will flower very early in the spring, and at a time when other flowers are scarce.

Salvias.—The kinds intended for autumn flowering, as well as those to succeed them in winter and spring, should by this time have their pots tolerably filled with roots, and from their naturally strong vigorous habit they with difficulty retain their lower leaves, or keep in a healthy green colour, unless they are assisted with liquid manure; but in this it is necessary to proceed with caution and not to apply it so strong or so often as to excite an undue amount of growth, as after this time it is better to treat the plants with a view to maturing the growth which they have already made than encourage its extension further.

Greenhouses.

Where any inside painting has to be done there should be no delay, in order that the houses may be fit for the reception of the plants now placed out-of-doors. Before housing them the glass should also be well washed, and where no painting is required the woodwork also as well as the stages, and any repairs needed should be attended to. Where there are any defects in or insufficiency of piping, it can likewise be best set to rights at this season.

Camellias.—Any of the latest flowered plants which have been late in making their growth will be now about setting their buds, and in the case of those that want more root room, they should at once be placed in either larger pots or tubs, as by being moved now their flowering during the coming spring will be little affected, and through the autumn they will have time to root into the new soil, which will evidently place them in a much better position for making growth next year than if the potting were deferred until after they had bloomed in the spring, when their roots are in the tenderest condition. Those who have not potted these plants in this stage of their growth will, if they give it a trial, find it the best. Camellias are plants that require little training, and should not be submitted to the twisting and interlacing sometimes practised, and when they have got into a thin straggling state heading down is often the best remedy. But yet with plants in such a condition any strong branches may with advantage be tied in to a moderate extent when the work is done, so as not to give them a formal appearance; but branches so treated should not be bent down too much, or they generally cease to make further growth from the points, simply pushing out young shoots where bent.

Oranges.—Where these are turned out-of-doors in the summer after their growth is made, it is doubtful whether they are ever benefited by such exposure, especially if the plants are deficient of roots proportionate to the size of the pots or tubs they occupy. Specimens in the best of health should at once be got under cover, for although they often bear a good deal of indifferent treatment and seldom die suddenly, it is a very common occurrence to see them in a dwindling state. They come from latitudes too warm to be benefited by exposure to the fluctuations of our climate. Previous to taking them in, it is well to give them a thorough cleaning, especially where affected with scale, as at this time when such as have been thus out-of-doors will have made early growth, and had their wood and leaves hardened up, they are much less likely to have their foliage injured by the sponging and brushing necessary to remove the insects. The removal of the dirt deposited on the leaves by brown scale is essential to keeping them in a healthy condition.

Fruit.

Gathering fruit as it ripens is now an important point, and requires great attention. Fruits must not be gathered when wet, nor during hot sunny weather, and they must be handled very gently. In the case of early Pears it is not well to leave them on the trees until they are quite ripe; and as a rule they should be gathered a day or two before they are in that condition, otherwise they are apt to become dry and rotten at the core. The choicest wall fruits should be protected from wasps, birds, and flies with hexagon netting or other material of that kind. Remove all unnecessary lateral growths, and expose the fruits as freely as possible. Morello Cherries should now all be gathered, the trees thoroughly cleared of vermin, and the new shoots of the current year nailed or tied in. Established Strawberry plantations should have all the runners cut off, and the ground between the rows "pointed" over, and afterwards thickly mulched with good manure. Newly-planted plots should also have the runners persistently pinched off. The plantation made with the earliest forced plants may be expected to fruit freely this autumn, and for these a layer of clean straw to keep the fruit clean should now be applied. The ligatures of grafts ought now to be removed, and the shoots produced by the stocks should be kept rubbed off. In some instances, such as where the union has not been properly established, a temporary tie may be requisite, in order to prevent injury from windwaving.

Vines.—Now is the best time to cover outside borders attached to Vineries in which Grapes are intended to hang during the greater part of the winter; when delayed until further on in the season the soil often gets thoroughly wet, and the benefit which should result from covering is never realised. Where the border is thatched or covered with litter clear it away, and lightly fork over the soil before putting on the covering. Thin deal shutters, in breadths of 6 ft. by 12 ft., make the best protectors. One end should be placed close against the front of the house on two bricks, one above the other, and a shutter 12 ft. from this is generally sufficient protection. The lower or bottom end should rest on one brick; thus sufficient incline is given to throw off the water, and space is left between the boards and the soil to allow a free circulation of air. Glass sashes do just as well as wooden shutters, but during autumn and winter these are generally needed for other purposes. Tarpaulin may be used where neither of these protectors can be had, but it is inferior to both of them.

Vegetables.

Sow American Red Stone, White Stone, and Strap-leaved Turnips on Potato ground, and hoe and thin previous sowings, always using the most advanced roots first. Sow Radishes according to the demand in a warm position; the early autumn sowings generally yield first-rate produce. Sow some Spinach for spring use, and also some Early Horn Carrots on a warm border for the same purpose. Earth up Leeks as they grow. Clear away exhausted crops of French Beans. Potatoes, when lifted, should be stored in a dry place, and not laid more than 1 ft. or so in thickness. Under such conditions, they can be turned over three or four times at intervals of ten days or so, each time picking out any that show signs of decay. Those that remain sound after that will be likely to keep. Potatoes should always (but more especially when disease is prevalent) be stored in a cool and thoroughly dry shed, where air can get to them, except in frosty weather. As a matter of course, they must be kept in the dark, or they will become more or less green, which impairs their value as food.

GLASSHOUSES AND FRAMES.

HYACINTHS IN POTS.

Now the various bulb catalogues are daily reaching us it reminds us to say a few words on the culture of the Hyacinth. The first thing is to have fine, heavy bulbs to start with, although there are exceptions to this rule. Many varieties never make large roots, but form, notwithstanding, magnificent spikes. Do not, therefore, be disappointed if you buy a few small bulbs; but the great average should consist of large roots, which should, as said before, be weighty and plump, not light and loose or advanced in growth. The better the bulbs, the better the flowers assuredly are. Much also depends on securing the bulbs early. Orders should be given early, for the first-comer is the first served, and carries off the cream of the bulbs. Again, early potting secures early rooting, and early rooting strength and health. No Hyacinth will force satisfactorily unless it is made first to root well; and without this is attended to, the finest bulb will do badly, and only prove a mortification to the grower and be an utter failure.

The soil for the Hyacinth should be rich, light, and porous, and rather loose. It is one of those bulbs that does not like firm potting, and cannot endure cramming in; above and around the bulb the soil should be but slightly pressed; the latter should be a sandy loam, but mixed with old decayed cow manure; drain liberally, and fill a 6-in. pot up to rather above one-half, put a thin layer of clean, sharp, silver sand at the base of the bulb, place the bulb upon it, cover the crown, but do not bury it; let the soil be in a fair state as to moisture, for the bulbs will not receive water for some time. The next step is to choose the right place and treatment for the development of the roots; it is obvious that if the pots were placed in full light that the tops would come forth in advance of the roots. This is the one thing to be guarded against at this stage; we must first have roots in strength and number; place the pots in a cool, well-drained, dry situation in the garden—best in an old frame with the lights off—and place a 3-in. pot over each bulb; this will keep it clean and from rotting; cover the drain-hole of the pot with a small stone or potsherd, and place about 6 in. to 9 in. or 1 ft. thick of clean ashes over them, taking care that the sides of the frame are also well covered with this material. The darkness and seclusion encourage root growth, and in about six weeks the pots will be quite full of roots, and the tops will start with strength and vigour.

Practically after four weeks the ashes should be removed, and a more moist substitute, such as Cocoa-nut fibre or spent tan, should replace them. Now the pots should be moved into a low, well-lighted house, and be placed close under and near the glass—not on a shelf, however—this does not suit them, but on a moist substance or ashes; the small pots should be left over the bulbs for a while, so that the young growth may get steadily used to the light; many growers leave a 4-in. pot over the bulbs for some time. The flowers will grow towards the light, that is, towards the opening in the top of the pot, and the leaves will keep down. This is a very essential point, and one to which much attention should be given. The leaves should stand well under, never above, and never covering the spike; and keeping the pot over the bulb will be the first step towards obtaining fine dwarf leaves. If quick forcing be wanted, the pots should be placed on a bottom-heat of 60° or 65°; the flowers will start with extraordinary rapidity, but greater strength will be obtained in a temperature 5° lower. In adopting this mode of forcing, great care must be taken in applying an excess of heat; the roots must also be thoroughly watered once or twice a day; do not let the material on which the pots stand get dry, but keep it very moist. A Hyacinth once dry enough to flag is half killed. With pots well drained it is next to impossible to over-water.

Doubtless Hyacinths flower best forced slowly into blossom, and we should advise a top temperature of 55°. Strongly grown and richly nourished with manure water, they will need the support of wires or sticks; the succulency of their stems and the strength of their flowers prevent them from standing alone with safety. Almost all nurserymen sell wire supports of the most improved forms at a very low rate. Early white Roman Hyacinths should be potted in August or September. Planted in a pot and forced, they flower quickly, and are very handy for cutting before Christmas. They are useful for bouquets and decorative purposes. F. S.

Sowing Auricula Seed.—A 6-in. pot is well adapted for Auricula seed. The pots should be nearly one-third filled with crocks, and over these a little coarse soil should be laid before the fine soil is added. A good seed soil is made up of finely-sifted loam, leaf-mould, and some finely-powdered charcoal. This should be put into the pots till within ½ in. of the rim, then press down gently till level, and the seed thinly spread over it; then the seed should be pressed into the soil, a piece of glass placed over each pot, and then put away in a cool shady part of a house or frame, shading from the sun as requisite. If the soil be used a little moist, no water will be required for a few days, but it is best to keep the soil in the seed pots fairly damp. If it gets dry, it is a good plan to place the pots in water up to the level of the soil, and allow it to rise in the soil, and gradually moisten the whole. There is a great amount of interest attaching to the raising of seedling Auriculas, especially when the seed is saved from choice flowers, but there are cases in which fine varieties have originated as chance seedlings.—D.

Souvenir de Malmaison Carnation.—This deserves a place in every garden where cut flowers or choice decorative plants are in request. The blooms are extremely large, and of a very delicate flesh colour. Young plants are preferable for pot culture; those struck in May from soft side growths in a brisk bottom heat flower within twelve months. They should be potted off into 3-in. pots in a compost of fibry turf and dry cow manure, and as soon as they are well rooted transferred to cold frames, in which they are set on coal ashes, the lights being drawn off entirely on all favourable occasions. In August they should be shifted into 5-in. and 6-in. pots, great care being exercised in watering, as if at all soddened or the drainage imperfect the plants are liable to die off. Green fly must be guarded against by fumigation or the use of Tobacco water. During winter they should be kept in a light, well-ventilated house with intermediate temperature. Such plants, if successfully handled throughout, develop splendid heads of bloom.

Plumbago capensis in Small Pots.—This, when grown in pots, is usually trained over a balloon-shaped trellis, and little is thought of it until it attains an exhibition size. When planted out it drapes a wall or rafter with excellent effect, but it is seldom one sees well-flowered plants of it in 5-in. or 6-in. pots. A week ago, however, we saw some twenty or thirty plants of this description, remarkably showy. They were in 6-in. pots, and each plant was furnished with from two to four shoots, each of which bears in succession or otherwise from three to five handsome clusters of blossom, the colour of which no other plant in cultivation can supply. These plants were not more than from 12 in. to 18 in. high, pot included, and for vases or mixing with other plants in small conservatories, and similar purposes, they are admirable. After flowering the plants should be rested and the wood well ripened, and if dwarf plants are required they should be cut down to within a few inches of the base, when they will send out shoots in spring, and yield abundance of flowers during summer and autumn. If large specimens are required, there is no reason why they could not be grown into a bush as well as other plants, and in this way they would be much more effective than formal trellis-trained plants.—S.

A Good White Pelargonium.—White flowers amongst zonal Pelargoniums are always valuable for bouquet making, and they may be had, with little trouble, every month in the year. The greatest difficulty, however, has hitherto been to obtain a kind which would flower freely, as most white Pelargoniums of the Madame Vaucher type are strong growers and shy bloomers, especially in a young state. Jean d'Arc and White Vesuvius will supply this want. In habit and leaf the former closely resembles the well-known pink Christine, whilst its flowers, which are produced in great profusion, are large, well-formed, and of the purest white. During winter this Pelargonium would be especially valuable, and any one having good plants of it, the wood of which is well ripened, would have no difficulty in obtaining a good supply of bloom during the dullest months of the year. White Vesuvius is exactly the counterpart of the Scarlet Vesuvius as regards habit and freedom of bloom.

TREES AND SHRUBS.

Pruning Conifers.—I noticed the other day a fine plant of Pinus Pinsapo, the lower branches of which had a few years ago become rather straggling and bare, and which were therefore pruned back in order to get them to make fresh growth. This plan has resulted satisfactorily, for the branches at the bottom are now as dense as at the top, and equally green and healthy. No one need, therefore, fear to prune Pinus Pinsapo should such an operation become necessary.—S.

Jasminum nudiflorum aureo-variegatum.—This is one of the best golden-foliaged wall climbers at this season of the year that we possess. It is a vigorous-growing plant, and one which ought to be cultivated by every one who values a contrast of colour on open walls, and it is as hardy as the type.—J. G.

Aspidistra lurida variegata.—This is one of the best plants that can be grown either in windows or greenhouses, being of easy culture and rapid growth, and making fine, healthy foliage, which, when well matured, will continue in good health in ordinary dwelling-rooms for a lengthened period; being of a smooth, shining character, too, it is readily divested of dust by sponging or syringing. This Aspidistra will withstand a wide range of temperature, but it retains its foliage best in an intermediate greenhouse.—J. G.

Ivy on Rockeries and Rootwork.—The small-leaved variegated kinds of Ivy have a pretty effect when introduced here and there amongst rock and rootwork. Being of comparatively slow growth and of smaller dimensions than the green kinds, they are easily kept in bounds, and do not encroach upon the other occupants of such places. If trained along the lower part of rockwork they form a neat and pretty edging, affording a charming contrast to Ferns and other dark-foliaged plants. I have remarked that in a north or shady aspect the variegation is much purer and better defined than when they grow in full sunshine.—J. C.

Myrtles on Walls.—The Myrtle is scarcely hardy enough to withstand our severest winters as an exposed bush, but on walls it does well in most parts of the kingdom, and is most effective. Its sweet-scented, evergreen leaves are welcome at all seasons for mixing with cut flowers, and at this time of the year it will in most places be beautifully in blossom. Beyond firmly nailing the strongest shoots to the wall, no training is necessary, as it looks best growing freely with its spray-like growth loose and unfettered.—G.

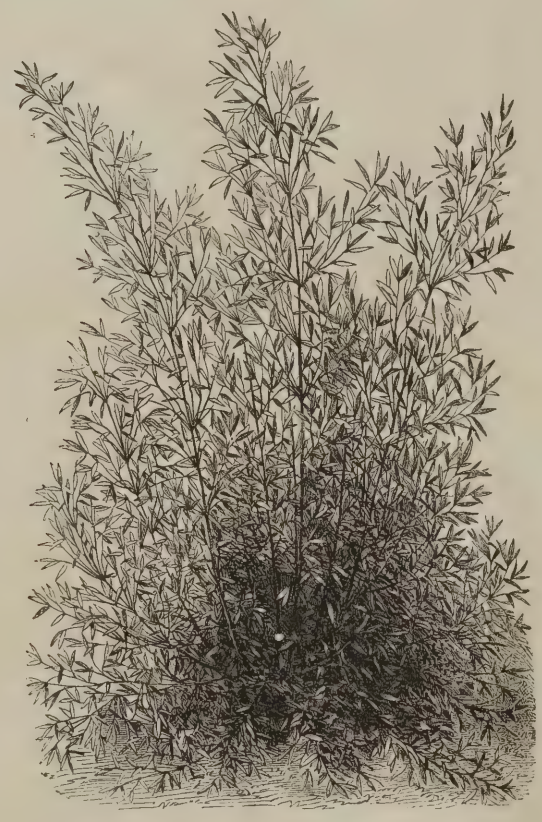
Salt-water Resisting Plants.—The Tamarisk and Sea Buckthorn will grow where washed by salt water, and the first is a very beautiful evergreen, having branches that hang over in graceful sprays, and in colour and form quite equal in appearance to many Fern fronds, and as useful as most of them for cutting to dress with flowers during the winter. The evergreen Oak succeeds uncommonly well quite close to the sea, and appears to enjoy the saline matter in the air; but whether it would grow in soils occasionally soaked with salt water, I know not, although I think it quite likely it would, if kept from them till they got their roots well down and became thoroughly established. If the ground can be thrown up into large mounds before planting, so as to get it above the general level, then Pinus Laricio and P. austriaca, with other hardy Coniferæ and other trees, might be made to succeed and form quite a feature in the landscape. The Spindle trees (Euonymuses) also succeed well near the sea.—S. D.

The Golden-stemmed Bamboo (Bambusa aurea).—This not very common Bamboo is one of the best for growing in unheated green-

houses. It is hardy only in southern counties, but given a little shelter under glass it thrives vigorously, and supplies abundance of lance-shaped, light green leaves, with wiry stalks for mixing with cut flowers. Under good culture the plant attains a height of 10 ft., but grown in pots or tubs 6 ft. probably would be the greatest height it would attain. Its stems are of a pale golden colour when matured. Moist, sandy soil suits the plant best.

ANSWERS TO QUERIES.

2749.—**Annual Perennials, &c., to be Sown Now.**—Having a greenhouse, there is no reason why it should not be utilised to the fullest possible extent by sowing annuals and perennials; but even under glass it is late to sow many such things in the hope that they will bloom next year. However, Hollyhocks, Pansies, Polyanthus, Myosotis dissitiflora and sylvatica; Aquilegias or Columbines, such as cœrulea and chrysantha; pot Marigolds, Lobelias, Pentstemons, Wallflowers, Antirrhinums, Sweet Williams, Canterbury Bells; and of greenhouse plants, Cinerarias, Primulas, and Calceolarias; of annuals, Candytufts in colours, especially the new carmine, Nemophila, Silenes, Saponaria, Chrysanthemums, Stocks (Ten-week and Intermediate), Mignonette, Bartonia aurea, Eschscholtsias, and indeed almost any hardy annual, of course, if sown so early, it will be difficult to keep these things from getting much drawn in a greenhouse. Iresine and Amarantus you could not winter in an ordinary greenhouse. Get cuttings of the first and sow seed of the other in spring. Echeverias will keep very well. Get cuttings of Pelargoniums and Fuchsias and strike them at once.—A.



The Golden-stemmed Bamboo (Bambusa aurea).

2750.—**Inferior Pelargonium Blooms.**—You doubtless allude to the ordinary forms of zonal Pelargoniums, and as no plants, as a rule, flower more freely or abundantly at this time of the year, we can but assume that your plants are either kept too dry at the roots, or are starved, or are in soil which the roots do not like. If you have plenty of light and air it would be useless to advise the giving of more, but if the plants are grown in a room, there may be some other conditions in the atmosphere not known that may cause the trusses of flower to die off. But for what you say we should have at the first advised more air and plenty of it, although no flowering plants are, as a rule, more free to bloom anywhere in pots, boxes, vases, windows, houses, or in the open air, than zonal Pelargoniums.—D.

2743.—**Wintering Plants.**—As long as frost does not exceed from 8° to 10°, a turf pit may do very well for the housing of certain kinds of plants, but when that is exceeded, then it is only by covering all over and around the sides with litter that frost can be excluded, but at what cost! You say the bottom of the pit is dry; perhaps it is now; but how will it be in the winter when the earth is full of moisture? Then if the pit is covered up close for a few days even you will be surprised to find how prevalent damp and mould is amongst your plants, and you will wonder where the moisture came from. When all the soil outside is locked up in frost, the thermal moisture will be only too pleased to find means of escape into the air through the bottom of your pit, and it will cause your plants to damp off fearfully because there is no room for its escape. It would be worse than folly to advise the wintering of plants that are tender in a mere cold pit or frame of any kind. An oil lamp may help to exclude some frost and absorb some of the damp air, but these things always break down just when most needed, that is, in very severe weather. It will be far better to keep the plants in rooms and windows where the frost can be excluded; but to make sure that such is the case, a small thermometer should be hung just inside the window, and if this showed a low, dangerous temperature within at night, then the plants should be removed to a safe distance from the window. Of course all kinds of hardy or some half-hardy plants may do in a cold frame all the winter, but if the weather necessitated the keeping it covered up for several days or weeks at a time, the things you name would inevitably only escape the frost to be killed by damp. Your Primulas, &c., may do in the frame very well until the end of even November, but not later.—A. D.

2780.—**Onion Maggot.**—Soot is one of the best remedies for Onion maggot. Its tendency is to prevent the fly that produces the maggot from depositing its eggs. Dress the land heavily before sowing the seeds, and give lighter dressings in spring. Salt also is beneficial, especially in dry seasons, by inciting the plants to rapid growth. Nitrate of soda may be beneficially used with a like object. Heavy dressings of charcoal-dust, or the bottoms of fire-heaps where rubbish has been burnt, are useful.—E. H.

2742.—**Storing Potatoes and Cropping a Garden.**—When taking up the Potatoes select the handsomest-shaped, medium-sized tubers for seed, and lay them thinly in a cool shed for the skins to harden. Afterwards pack them away in single layers, if possible in some light frost-proof place. As regards cropping his garden, "Alphonso" must read and study Gardening weekly; to go into details as to the cropping of ½ an acre of land for the season will require more space than the editor can give to it now, even supposing I had the time to write, which I have not. March is the fittest month for general spring sowing and planting. In that month, selecting a time when the land works well and cleanly, Potatoes should be planted. Peas, Beans, Onions, Parsnips, Carrots, Lettuces, Cabbages, Radishes, Brussels Sprouts, Spinach, Parsley, Celery, Leeks, Asparagus, and other things should be sown. The work for April is a continuation of March, with certain additions, such as sowing Broccoli, Cauliflowers, Vegetable Marrows, Beet, and at the latter end Scarlet Runners, and more Peas at fortnightly intervals up till the middle of June. In May and June successional sowings of various things will be necessary, and the planting of those things that require it from the seed-bed, such as Winter Greens, must be done promptly. Salading plants, such as Mustard and Cress, Radishes, and Lettuces, must be sown at frequent intervals all the summer. Celery will require pricking out. A slight hot-bed should be used for the sowing of this if possible, and plant into the trenches in June and July. At the end of the latter month or beginning of August the main crop of Cabbages should be sown; also Winter Onions and Spinach.—E. H.

2714.—**Clematis Dying at the Point.**—The points of the shoots of Clematis plants may have been injured by winds or possibly affected by electricity if growing upon galvanised wirework. The feature complained of is quite unusual, as the kinds named are very hardy and invariably do well. If neither of the probabilities above mentioned seem suitable to the case, then perhaps the roots have got into some sour soil, and would be the better to be replanted; but as the plants were planted so recently this seems hardly probable. The roots of the Clematis will feed freely on the surface if fed there with a mulching of manure and plenty of water given in hot dry weather. Fork the soil round the roots lightly, then add a mulching of long manure, and follow with a good soaking of water. This may induce renewed robust growth.—A. D.

2730.—**Uses of Ash Berries.**—It is possible to make jelly from the berries of the Mountain Ash, but not very profitably. Deduct skin and pips, and what is there left after the material has gone through the jelly bag? We once made jelly from the berries of the Berberis aquifolia, which are far more juicy than are those of the Mountain Ash; but the result was rather costly and the article not worth all the trouble. Apples, Plums, or Vegetable Marrows would make a preserve ten times more acceptable; and needing less sugar, the product would also be far more wholesome. As to the employment of the berries for Christmas decoration, that would chiefly depend upon the forbearance of the birds, who are rather partial to the fruit; and if gathered the berries would soon spoil and discolour. They are pretty on the trees; but there their merits are likely to end.—A. D.

2727.—**Edging Plants.**—Is it good taste to put a yellow edging to your borders? Does it not really border upon the vulgar? and would not the border look much better without this kind of decoration? To say the least, it is a tawdry style of gardening. If you prefer some such edging, we should suggest the silvery woolly-leaved Stachys lanata as better than the Golden Feather, and it is perennial; or you might have a line of the pretty silvery Sedum glaucum. This latter would be better than anything else for an edging. Nice clumps here and

there of Daisies, Pansies, Primroses, dwarf Campanulas, Saxifrages, and other dwarf hardy plants would be much more pleasing than any straight lines of edgings of any kind.—A.

2721.—**Cucumbers Dying.**—I remember being bothered with the same disease years ago in a house of winter Cucumbers, and I got rid of it by planting in stiffer soil and growing the plants in a lower temperature. I don't think there is any cure for it. When the canker attacks the roots nothing will save them; and the plants, even those that look healthy, won't stand a gleam of sunshine.

2806.—**Blooms Dropping from Scarlet Runners.**—The blossoms have not been fertilised, so they failed to set. The absence of insects might in some sense be looked upon as a disadvantage, as they are commonly fructified by bees and other insects. They will probably set better now the weather has become dryer, as the pollen will be in a more active condition.—E. H.

2789.—**Uses of Sewage in Gardens.**—The best way of using sewage is to pour it over the roots of plants requiring nourishment, such as Cauliflowers, Lettuces, Globe Artichokes, Peas, old fruit trees, Asparagus beds, &c. If too strong, dilute it with pond water. A mulching will be useful on the shallow soil over chalk, after the sewage has been given, to prevent too rapid evaporation. If it is not convenient to mulch, use the hoe freely.

2795.—**Greenhouse on East Aspect.**—Peaches may be grown in a house facing east, so also may Roses and flowers; but do not aim at too much at first. Plant the Peaches out along the front of the greenhouse, and train them on a trellis fixed about 16 in. from the roof inside. Plant the Roses against the ends, which they may be permitted to cover, or grow them in pots. The other flowers may also be grown in pots. Camellias, Heliotropes, and other plants for the supply of cut flowers may be planted near the back wall, and be trained to its face.—E. H.

2733.—**Club in Cabbages.**—Club in the Brassica family is caused by an insect. Plant on fresh ground if possible. If it cannot be had in any other way, trench it up from below, using heavy dressings of lime and soot. Frequent transplantings are useful, dipping the roots in a puddle composed of soot and manure water just previous to planting, trimming off all warty substances from the stems at the same time.

2794.—**My Failures.**—The Raspberry canes are probably too thick; thin them out now to let in sun and air to ripen them. Do not shorten them at all, but train them the full length by arching them over from stool to stool, tying their ends together. Give the Red Currants a good dressing of manure now, and fork it in lightly, just covering it. The Onions have been attacked by a fungus. In future dress the Onion bed heavily with soot in autumn before sowing, and again in spring.—E. H.

2734.—**Cinerarias Dying off.**—Are there any wireworms or other destructive insects in the soil? Examine it and see. Perhaps the drainage is defective or the soil not suitable. Good turfy loam with about a third of old mellow hotbed manure or decayed leaf-mould will do, adding some sand to insure the necessary porosity. Water carefully and ventilate freely.—E. H.

2735.—**Cucumbers Dying off.**—The soil is probably too light, and the plants lack stamina. Top-dress with some good sound loam with a little good manure mixed with it; press it down firmly. When the plants require water give them weak liquid manure, allowing it to stand in the sun a few hours before using it to take the chill off. A peck of soot tied up in a coarse cloth, sunk in a barrel of water, and allowed to stand a day or two, stirring it occasionally, will be suitable.

2799.—**To Keep Rain-water Pure.**—Keep it in an underground cistern and as little exposed to the air as possible. Make your cistern circular if small, oblong if large; have the bottom and sides carefully built of brick bedded in cement, and the top arched over. Cement the surface of the bottom and sides, and insert in the bottom, if necessary, a pipe to carry the water in, a waste pipe to carry off the overflow, a stone slab with a circular hole, covered with an iron plate for a man-hole, and a pipe for pump if required. If a small affair the water may be reached through the man-hole.—A. B. G.

2805.—**Dandelions on Lawns.**—The best and cheapest plan to adopt with the lawn in question would be to dig it over with a steel fork, picking out every Dandelion root or particle of root. Then make the surface fine and firm and sow a good mixture of fine Lawn Grass seeds. The beginning of next month would be a good time to sow the seeds.—E. H.

—— When these are in such force, as described by "Constant Reader," the best and most satisfactory way of proceeding is to dig the ground all over, and take out all rubbish and sow the lawn again, for which the present time is well suited. If, however, digging is objected to, they might be spudded out as deeply as possible, grass seed sown, and the lawn covered with a good compost. When the grass is all well up constant mowing and rolling shou'd be attended to. But these two latter operations cannot be depended upon to effect a cure by themselves.—James Carter & Co.

Orange-scented Gardenia (G. citriodora).

2793.—**Stove and Greenhouse Plants.** Gardenia Fortunei, G. radicans, Glonera jasminoides (a most free and continuous flowerer), Pentas carnea, Eucharis amazonica, Thyrsacanthus nutilans, any of the winter-flowering Begonias, such as Ingrami, Digswelliana, Dregei, manicata, and sanguinea, and Jasminum Sambac fl.-pl. In a temperate house, with an average temperature of 55° by day and 50° by night, Cyclamens would flower well if placed in a light position. Tropæolum Lobbi should be grown strong in the open air to be trained to the roof at the commencement of winter; Epiphyllums of various kinds best grown in baskets near the roof, Libonia floribunda, Fuchsia Dominiana, Heliotropes of kinds, Agathea cœlestis, Erica persoluta alba (the only kind that likes constant warmth), and Linum trigynum. You will succeed best by keeping them in pots, as they may then be treated according to their several requirements. Planting out for winter flowering in a glass house only answers when but one or two kinds of plants are grown.—J. C. B.

2755.—**Fruit Trees on Houses.**—On a south-east wall, therefore, with sun till noon, we have had for years a Green Gage ripening its fruit, as a rule, about the first week in August; a portion trained on to a north-east wall ripens its fruit some ten days later; they are equally good in flavour. Large Moorpark Apricots are at present ripening on the same wall. For fifteen or sixteen years a Peach tree flourished and yielded us delicious fruit; Nectarines have likewise done well. We have young trees coming forward of Coe's Golden Drop Plum and the Royal George Peach, and have no doubt the fruiting will succeed well. For a north aspect, if surface is of sufficient extent no fruit tree I know does better than the Syston Plum. Where a large space is to be covered by one tree, a means of utilising the empty wall rapidly is to put in stout cuttings of Red Currant 8 in. apart, and train them in upright cordons; these soon cover a space, and as the large fruit tree spreads, one by one can be dug up without sacrificing much room.—Midland County.

2786.—**Planting Bulbs.**—The month of

November is the best time in which to plant all kinds of border bulbs, or in pots or boxes if wanted for window or house decoration. Where bulbs are lifted from the borders in the summer that should be done as soon as the leaves are quite decayed, and the bulbs stored in paper bags in a dry cool place, or in very dry sand. Crocuses are the better not to be lifted, as are all similar bulbs that always keep best in the soil; but if in boxes the soil should not be permitted to become parched, but should be kept just as moist as the open ground would be. As far as pots are concerned, perhaps the bulbs are best out of them when ripe, as they are apt to get baked dry in the hot weather.—D.

2732.—**Cypripedium insignis.**—This Orchid belongs to the so-called cool section, requiring a night temperature of 45° to 50°, and 50° to 55° by day, to be increased if possible in spring to 60° by day and 55° by night. Like all the Cypripediums, it requires plenty of water at the root during its growing period, and should be placed in a light position in the structure, shading from hot sun. The greatest care must be taken to ensure perfect drainage, filling the pot half full of crocks, the compost to consist of fibrous peat of the best description, mixing with the same some chopped Sphagnum and small pieces of charcoal. During the winter season and when coming into flower, this plant may be kept in a warm room, and will expand its blooms perfectly therein. In fact, this Orchid makes an excellent window plant, and with careful attention in the way of sponging the leaves twice a week, might remain in the dwelling the whole year through. Those who desire a change in the way of subjects for their windows should try this plant. It is by no means difficult to grow, and charms by its novelty.—J. C. B.

2779.—**Culture of Coleus.**—The Coleus requires to be wintered in a temperature of 50° by night and 50° to 55° by day. Unless this amount of warmth can be accorded it, there is but little chance of bringing it through the winter. Cuttings struck now in a close frame, putting about six in a 4½-in. pot, and thus cared for, if potted off in March, will make fine plants by July. Or old plants may be wintered, keeping them on the side of dryness, taking off the young free shoots as early as possible. The Coleus likes a moist, warm atmosphere during the spring and early summer months, requiring a light situation, at the same time thriving best if screened from the hot sun. The soil should be free and rich—a good compost consisting of two-thirds leaf-mould and one-third loam and well-rotted dung in equal parts, adding thereto a good portion of coarse silver sand. The cuttings, however, strike best in sandy peat; and when they are potted off into small pots a little of this material added to the above-mentioned compost will be of service. Do not pot hard, and water carefully until the plants are well established. By the middle of July they will have developed into good-sized plants, and may then receive their final shift and be placed in a cool greenhouse.—B.

2797.—**Araucaria imbricata Failing.**—The roots have probably penetrated into a damp, sour subsoil. If that position of the garden where the tree stands is not well drained we would run a drain through it at a distance of some 30 ft. to 40 ft. from the stem, taking care to ensure a proper outlet for the surplus water. At the same time we would apply a top-dressing some 6 in. in thickness of good sound loam, which will have the effect of encouraging the formation of surface feeders. In this manner decay will probably be arrested.—J. C. B.

2718.—**Ferns for Shady Corner.**—Presuming that frost is to be excluded, any of the ordinary greenhouse Ferns would succeed in the position named. A suitable selection would be found in Pteris serrulata and its crested varieties, P. cretica albo-lineata, P. scaberula, Onychium japonicum, Adiantum Capillus-veneris, A. cuneatum, Asplenium bulbiferum, A. funcatum, A. lucidum, Platyloma rotundifolia, Davallia dissecta, D. bullata, Nephrodium molle, Lastrea glabella, Niphobolus Lingua, and Doodia caudata. With these may be grown such pretty Mosses as Selaginella Kraussiana and its variegated variety S. Martensi, S. Wildenowi; also Tradescantia zebrina, Panicum variegatum, and Nertera depressa, which forms a neat verdant cushion of foliage, studded in winter with scarlet berries. If a bare piece of wall exists plant Ficus repens, which will quickly cover it, and Lapageria rosea may be planted out (in peat) to cover the roof. The Ferns might be grouped around a nice Palm, such as Chamærops excelsa, Rhapis flabelliformis or Corypha australis, carpeting the soil between with Selaginella, a nice hanging basket or two completing the arrangement. Good subjects for the latter purpose are to be found in Platycerium alcicorne and Woodwardia radicans. Lygodium scandens and Selaginella cæsia arborea are climbing species both pretty and effective.—J. Cornhill.

2731.—**Spots on Rose Leaves.**—The plant in question is probably attacked by the larvæ of a small moth, which eats away the under surface of the leaves. They are exactly the colour of the leaf, are very small, and consequently not easily perceived. Hand-picking is the most effectual remedy.—C. B.

2808.—**Freesia refracta alba.**—Pot the bulbs about the middle of September in a tolerably light soil, consisting of two parts leaf-mould and one part turfy loam. Plunge the pots quite to the rims in a cold frame, keeping the soil just moist. Thus treated, they should start freely into growth.—C.

2723.—**Plants for Walls.**—You will find the following plants to do well in your house: Habrothamnus elegans, Jasmines of sorts, Lapageria rosea, L. alba, Plumbago capensis, Passiflora, of which there is some fine sorts.—E. L.

2751.—**Geraniums Turning Yellow.**—*A Learner.*—The cause of your Geraniums turning yellow must be the gas. The best way to do with the plant now is to cut it down, so as to leave a few eyes. It then will soon begin to "break" and make you a nice plant.—E. L.

2791.—**Columbines.**—All they want is shade. They do best in an east or north aspect, and require water in dry weather.—A.

—— If "H." had stated what the soil of his garden was, it would have been more possible to surmise the cause of his failure with Columbines. On the soil in my garden (upper oolite just below the chalk, of a light, sandy nature, and plenty of lime in it) Columbines do well, even the hybrid varieties, including glandulosa, which is a shy flowerer. The common kinds seed themselves freely in the border.—H. C.

—— The ordinary varieties of the Columbine are not fastidious with respect to soil. In a general way they reproduce themselves like weeds, needing but little or no care on the part of the grower. This family of plants, however, prefers a rather light, well-drained soil, some of the more tender species being apt to die off in wet winters in cold retentive soils. If your soil is naturally heavy add to it some leaf-mould or river sand, or light mould of any description. Sow in May and success will follow.—B.

2787.—**Pansies Rotting off.**—Woodlice are evidently at your Pansies, and there is no remedy but trying to trap them in flower-pots with some Moss in them, and in the morning scalding them in hot water.—A.

2720.—**Thistles in Meadows.**—Much patient labour will be required to get rid of the Thistles. Keep a man going over them with a scythe. If not permitted to make growth the roots will in time die from exhaustion.—E. H.

2757.—**Cactus not Flowering.**—Your Cactus not flowering is probably from your not using lime in the soil. I use half lime and sandy loam with good drainage of cinders, and unless the plants flag from October till March they get no water, and I have splendid flowers in June, but mine are red.—E. G. T.

2675.—**Climber for Scotland.**—Might I be allowed to suggest Tropæolum speciosum, as seen as a climber on Drummond Castle and all the houses and cottages for miles round?—J. M.

2783.—**Gooseberry Caterpillars.**—Most of the Gooseberry trees in this neighbourhood have been completely cleared of leaves by the caterpillar of the Saw Fly (Nematus Ribesi). The caterpillar of the V-moth (Halia wavaria) is also very destructive to the Gooseberry. I presume the trees of "Ruby" must have been attacked by the former.—W. J.

2751.—**Geraniums Turning Yellow.**—The roots from some cause or other have suffered injury. Allow it to get quite dry, then shake away all the old soil, cutting off the decayed points of the roots and repot in the same sized pot in a nice free soil. Place in a light position and water only when dry. In watering every second day you committed an error; plants must only be watered when the soil is dry, giving enough to thoroughly saturate it.—C.

2799.—**Sowing Everlastings.**—Helichrysums may be sown in the autumn to bloom early in the summer, but they must be kept in a frost-proof frame or greenhouse. Keep them in the open air until about the second week in October, and then place them under glass.—J. C. B.

2721.—**Cactus Turning Brown.**—This often occurs in the case of old specimens, and is generally a sign that the drainage has gone wrong. Turn the plant gently out of the pot, give fresh drainage if needful, and dust the old ball of earth with white sand, replacing in the same sized pot.—C. B.

2629.—**Vallota purpurea Turning Yellow.**—One cause of the leaves turning yellow is having the bulbs covered too deeply; half covered is quite enough; and in winter water seldom. Just when the leaves feel a little soft give a thorough soaking, but do not leave water in the saucer.—E. G. T.

2700.—**Irish Ivy.**—I read in Gardening Illustrated of the 7th that a gentleman signing himself "R. A. M." wishes for plants of Irish Ivy. I should be very happy to send him a bundle of the finest by rail if I knew name and address, and if he thought it worth while. The month of October or November would be the best time.—J. A., *Co. Carlow.*

2738.—**Evergreens for Covering Rustic Work.**—There can be nothing better than Ivies for the purpose, such as algeriensis, the large-clouded white, the small-leaved variegated variety, and the common Irish. There are also Cotoneaster microphylla and the evergreen Roses, which are of quick growth, very hardy, free flowering, and vigorous.—J. C.

2792.—**Honeysuckle Dying.**—It is impossible to give a reason for the plant dying off in the manner described. We can only imagine that it has sustained some injury at the root. The situation is favourable, and the soil is suitable. In early spring cut it back to the healthy part; it will probably grow away freely; if it does not, root it up and plant another.—B.

2725.—**Orange Trees and Jessamines not Blooming.**—As the plants in question are making good healthy growth, there can be only one reason for their not flowering. It is evident that the wood does mature. At this period of the year place them where they get plenty of light and enjoy a free circulation of air. The Orange tree should get no shade from this time.—C.

2795.—**Aspect for Rose and Peach House.**—You could not place a house for Roses or Peaches in a better aspect than east or south-east.—J. F.

2781.—**Leeks not Growing.**—It is not easy to see without more details where the management has been wrong. Have they been planted long enough to become established? Perhaps the soil has been pressed too firmly round the stems. Loosen the soil up deeply between the rows, and keep the surface freely stirred. I have no doubt with such treatment an improvement will be soon visible.—E. H.

2801.—**Grass Going Brown.**—We suggest that the brown appearance and bare places are caused by cutting the Grass too short, and especially in hot, dry weather. The best treatment will be to sow seed on the bare places, give a slight top-dressing of manure over all, and water in the evening in dry weather, keeping all traffic from it until it is green again. Set the knives of the mowing machine as high as they will go.—James Carter & Co.

2785.—**Lily of the Nile not Flowering.**—It is probable that your Calla does not throw up flowers because the bulb has not attained to sufficient size. The getting of flowers is all a question of cultivation the preceding year. The plant now would be better in the open air, and even better still if it had been planted out in the open ground in the spring, and lifted again in the autumn. As it is, the plant should be incited into growth with a little weak manure water, and be kept standing in a saucer in which there is always a little moisture.—D.

2787.—**Pansies Rotting off.**—It is a common complaint of Pansies and Violas thus to suddenly collapse and die off. There is no known remedy for it, nor can the cause be ascertained, but it is more common in hot weather than at any other time. It is a kind of shanking, and is a cause of great annoyance. We have found autumn-planted Pansies to be much less subject to it than spring planted ones are. It may be alleviated if the soil be kept stirred, and a thick top-dressing given of either old pot soil or Cocoa nut fibre refuse.—D.

2726.—**Bedding Violas.**—The best blue Viola for perpetual blooming, though the flowers are rather small, is Bluebell; but the best really blue hybrid Viola or bedding Pansy is Blue Beard—the habit dwarf and the flowers a deep colbat-blue. The best summer yellow Viola is Sovereign, dwarf and very free; but the best spring yellow Viola is Yellow Boy, because so very early. The best white Violas are Vestal, a true Viola of good quality and substance, very free and effective; and Mrs. Pease, having larger flowers, free and telling.—A.

2728.—**Violas for Continuous Blooming.**—To secure a constant supply of bloom from Violas it is best to have a quantity of plants put out in the autumn to flower in the spring, and again a fresh lot planted out in the spring to flower through the summer. To get a good stock of young plants for winter planting, all the bloom should be cut away now to enable the new growth to spring up from the roots; but it is the autumn-planted Violas that should be treated thus, and not those planted in the spring, to furnish a summer display.—D.

2662.—I have never seen any explanation or preventive of Calceolarias behaving as described but one, and that is contained in the two words "plant firm." Press the earth well to the roots in planting, and see that it does not become loose afterwards.—J. D.

Although the following questions are answered by the Editor, he will be obliged to any of our readers who may think well to answer them again.

2847.—**Standard Currants**—*E. B.*—We do not know of any nurserymen who keep standards, but it is not at all a difficult or a long task to grow good, strong plants into that form.

2848.—**Distribution of Plants at London Parks.**—*Phlox.*—Public announcements are usually made in regard to this matter.

2849.—**Window Plants Failing.**—*Ignoramus.*—Plants bought from the market seldom last long in windows. The only way to succeed is to begin with young plants and grow them in the window.

2850.—**Watering Musk.**—*Ignoramus.*—This needs plenty of water, but not too much overhead, or too much left in the saucer.

2851.—**Best Time to Sow Flower Seed.**—What is the proper time to sow Lupinus seed, Jacob's Ladder, Sweet Williams, and Sweet Peas?—A. H. C. W. [Autumn or spring.]

2852.—**Phlox Drummondi.**—*Phlox.*—This is not a hardy annual, and should be sown in February in a frame and planted out in May, or sown in March in the open air.

2853.—**Carrot Basket.**—*Butterfly.*—Cut a piece off the top of the Carrot, scoop it out and fill it with water,

letting the crown of course be downwards. Suspend it with thread or fine wire. When it grows train the green tops up the wires.

2854.—**Ivy-leaved Geranium for Bedding.**—Would the Ivy-leaved Geranium named Kœnig Albert answer as a bedding-out plant? The flower is lilac and double. It succeeds well in our cool greenhouse.—M. W. [Yes, if pegged down.]

2855.—**Old Myrtles.**—I have several fine Myrtles in pots, two of the same being more than twenty years old. Previous to last winter they were in a flourishing condition; since that time, however, they appear to be declining. Can any one recommend any particular treatment to be applied to them?—L. B. [Place them out-of-doors for a month or so, putting them in an open, but not too sunny a position. In spring they may be pruned back, and if placed in a warm house or frame and kept syringed, will make bushy plants again.]

2856.—**Climbers in the Open Air.**—Will Bignonia radicans, Clematis lanuginosa, and Passiflora cœrulea grow in the open air on a 5-ft. wall facing S.W.? The situation is on a hill in the suburbs of Bristol; the soil is of a clayey nature, but has been dug several times; and what is the right time to plant?—C. H. B. [All will grow, no doubt, fairly well if you add plenty of well-rotted manure to the soil, and a lot of road sand or Grass cuttings from the edges of roads or walks; also give good drainage. Plant now or in spring. Cover the roots with ashes in winter.]

2857.—**Currants for Show.**—*Ignoramus.*—Black—Black Naples, Lee's Prolific, Goodall's Seedling. Red—Raby Castle, Red Versaillaise, Red Cherry. White—White Dutch, White Cut-leaved, Victoria.

2858.—**Hardy Plants.**—*William Hirst.*—All the plants you name are perfectly hardy in well-drained soil. If you wish to move any of them the present is a good time for the operation. A coating of good rotten stable manure would do them no harm.

2859.—**Cropping Vines the First Year.**—*Roseville.*—If the canes are very strong when planted they might be allowed to carry one bunch of Grapes each next year, but if weak it would be better to sacrifice the fruit for at least one season, and crop only lightly the next.

2860.—**Roses for Walls.**—*J. G. C.*—Gloire de Dijon is one of the best light Roses, and General Jacqueminot is a capital red kind.

2861.—**Propagating Araucarias.**—How are Araucarias propagated?—A RUMMUN. [From seed imported from the native habitat (Southern Chili) of the Araucaria.]

2862.—**Fuchsia fulgens for Pillars.**—Is this Fuchsia capable of being trained against a wall to any height as a pillar Fuchsia?—WARWICK. [Yes; it is one of the best for the purpose.]

2863.—**Fruit Eaten by Wasps.**—My Plums in North Wales are all being eaten before they get ripe by thousands of wasps. What must I do to destroy them—SUBSCRIBER. [Take their nests when possible and use Scott's Wasp Destroyer, which can be obtained at any good seed shop. Of course we presume the trees are too large to be covered with tiffany or muslin.]

2864.—**Mildew on Roses.**—*Scotus.*—This is very prevalent at this season of the year. Well syringe the trees with water in which has been dissolved some flour of sulphur, or dust the leaves with sulphur from a pepper box. Also give plenty of water at the roots, and put a coat of rotten manure on the surface of the soil, to be forked in next spring.

2865.—**Violets for Windows.**—*W. H.*—If you lift some roots in September with a good ball of earth adhering to them, and drop them into well-drained pots just large enough to hold them conveniently, and place them in a shady situation for a week or so, then expose them fully to the sun and air, and house them when cold weather sets in, you will doubtless get them to flower early in spring.

2866.—**Soil for Vines.**—I am informed that red clay, ground, and lime mixed are good for Vines; is this correct?—P. N., *Jersey.* [Yes; when plenty of good turfy loam is added and a few bushels of inch bones.]

2867.—**Slow Combustion Stoves.**—There are now so many stoves for heating greenhouses (many of which are excellent in their way), that we cannot undertake to recommend any particular one. Consult our advertisement columns from time to time. There were some very good stoves advertised in Vol. I.

2868.—**Geraniums in Windows Turning Yellow.**—*Amateur.*—Place them outside and wash the leaves occasionally, and give them a little clear soot water once or twice a week. It can easily be made by putting a handful of soot into a bit of canvas, and sinking it in a can of water for a few hours.

2869.—**Sowing Geranium Seed.**—Should Geranium seed be shaded after being sown in August?—E. W. B. [Yes; till it germinates.]

2870.—**Pruning Black Currant Trees.**—*J. E., Dunstable.*—Do not prune now. In winter cut out a few of the oldest and barest branches. The Black Currant bears its fruit on the young wood.

2871.—**Green Caterpillars on Window Plants.**—*Amateur.*—Caterpillars are very prevalent this year. We know of no effectual remedy but that of picking them off morning and evening and killing them.

2872.—**Tuberous Begonias from Leaves.**—*Heath End.*—This would be a troublesome process if it succeeded, and as plants can be raised from seed in a few weeks it is not worth the trouble, we should say. If you try it, take off matured leaves, stalk attached, and, if possible, a bud at the base of the stalk. Insert in sandy soil in a hotbed, and cover with a bell-glass.

2873.—**Oleander Covered with White Scale.**—*N. C. L.*—Well sponge the leaves with strong Tobacco water, after which well wash them with soap and warm water, using a tooth or nail brush for the purpose. In a week's time repeat the operation, and do all you can to encourage the plant to make free growth.

2874.—**Seedling Solanums.**—*M. S. B.*—Pot them in any good sandy well-drained soil, and place them in a frame close to the glass, keeping them rather close and moist, and stopping the shoots occasionally to make them grow bushily.

2875.—**Rhynchospermum and Hoya in Cool House.**—Will Hoya carnosa and Rhynchospermum jasminoides grow on wall of cool greenhouse where it is difficult in winter to exclude frost?—ERIN. The Rhynchospermum would probably succeed, but the Hoya wants more heat.]

2876.—**Storing and Cooking Salsify and Scorzonera.**—*Erin.*—In October or November when the tops have withered, and before severe frost sets in, dig up the roots, taking care not to break them; wring off the tops with the hand and store the roots in a cool shed or cellar, packing them in layers one on the other, with plenty of dry sifted soil or sand, and use as wanted. As regards cooking, scrape off the outside skin, and put them in cold water. Cut them in pieces about 3 in. or 4 in. long, and put them in boiling water. Boil them from forty to sixty minutes, or till tender; then drain, and serve them with white sauce, rich brown gravy, or melted butter; or, when boiled, dip them in stiff batter, or in bran tea boiled to a strong jelly, and fry them; then serve with brown sauce, &c. When boiled, mashed, formed into cakes, and fried in butter, they are said to have the flavour of oyster patties, or of smelts.

Cuttings of Begonias.—*Amy.*—Pot them on; it is not too late to strike more cuttings.

Ferns.—*T. M. M.*—Apply to some Fern dealer. See our advertisement columns.

Book on Roses in Pots.—*W. W. C.*—Paul's "Roses in Pots," price 2s. 4d., post free from our office.

Primulas Showing Flower.—*W. B. W.*—Pinch out the flower-buds as soon as they can be seen.

Disease in Melons.—*T. G. B.*—It appears to be a fungus, but we can suggest no cause for its appearance. Rub a little quicklime into the affected parts.

Heating Greenhouses.—*P. C. Stanmore.*—If you get a medium-sized tubular boiler it will heat three houses of the size you name with ease, and will need but little attention. Consult some horticultural builder.

Currants for Dessert.—*J. G. C.*—The best White dessert Currant is the White Dutch, and the best Red is the Red Versaillaise.

Large White Convolvulus.—*A. E. T.*—We suppose it is a variety of the common Cornbind (Convolvulus arvensis).

Planting Strawberries.—*G. B.*—We have lately given several exhaustive articles on this subject.

Number of Pots to a Cast.—*Inquirer.*—There should be seventy two thumb pots to the cast.

Book on Amateur Gardening.—*R. B.*—You cannot have a better book than the first volume of GARDENING ILLUSTRATED. It contains more information for the amateur than any book you can get.

Book on Small Kitchen Gardens.—*E. W. B.*—Hobday's "Cottage Gardening," price 1s. 9d., post free from our office.

Book on Gardening.—Which is the best and cheapest book on gardening? [GARDENING ILLUSTRATED.]

Books on Roses.—*R. G. H.*—"The Rose Garden," by Wm. Paul, 10s. 6d., coloured 21s; Hole's "Book about Roses," 7s. 6d.; Rivers' "Rose Amateur's Guide," 4s. 6d. All post free from our office, 6d. extra.

Book on Mushroom Culture in Orchard Houses.—*Kincora.*—The best book on the subject is "Mushroom Culture in England and France," by Wm. Robinson, price 1s. 9d., post free from our office.

W. R.—We do not understand your query.

Names of Plants.—*Pat.*—Omphalodes linifolia.——*A. P. H.*—Dictamnus Fraxinella alba, Melittis Melinophyllum.——*M. S. B.*—Macleaya cordata, commonly known as Bocconia cordata.——*Alpha.*—It looks like a Sedum of some kind. Send better specimens.——*Scotus.*—Echeveria of some kind. Lift in October and place in a dry cool house or pit. Very little water is needed during winter; damp is worse than frost.——*Mrs. H.*—1, Bartonia aurea; 2, Silene pendula alba; 3, Viscaria agrostemma probably.——*Const. Sub.*—Desfontainea spinosa.——*Sposa felice.*—Crassula (Kalosanthes) coccinea.——*Richmond.*—Begonia Rex. The leaf is very thin; give the plant more air and light.——*W. R. T.*—1, Achillea ptarmica; 2, Origanum vulgare.——*M. C. R.*—Spiræa callosa.——*A. Millard.*—Annual Spiderwort (Commelina pilosa).——*Newt.*—Siebold's Stonecrop (Sedum Sieboldi).——*R. P.*—Apparently Catalpa bignonioides. 1, Verbascum nigrum; 2, Potentilla atro-sanguinea; 3, Centranthus ruber.——*Rev. St. A.*—Heuchera ribifolia. Fern not recognisable.——*E. J. R. R.*—1, Adiantum cuneatum; 2, A. formosum; 3, Pteris serrulata; 4, P. cretica albo-lineata.——*G. A., Kent.*—Eccremocarpus scaber.——*C. H.*—Eupatorium cannabinum.——*P. S.*—Silene viscosa.——*H. C.*—1, Campanula fragilis; 2, C. muralis; 3, Veronica austriaca.——*Jellalabad.*—Euphorbia Lathyrus.——*F. A. S.*—Sedum album, Campanula rotundifolia.——*A. B. C.*—Adiantum Capillus-veneris.——*C. J. H. S.* Lysimachia punctata ——*J. R.*—Devil in a Bush (Nigella damascena).——*Anon.*—1, probably a Pyrus, but cannot say without flowers or fruit; 2, White Poplar (Populus alba); 4, Tulip Tree (Liriodendron tulipifera).

QUERIES.

2877.—**Making a Garden.**—I have a piece of land, which I intend to convert into a garden; it is of a clayey nature. So far I have merely dug it up roughly. Would any kind reader advise me how to proceed?—A. O. A.

2878.—**Cocoa-nut for Ornament.**—Can any one inform me if the Cocoa-nut can be grown in an ordinary greenhouse? If so, what treatment does it require?—C. W.

2879.—**Striking Rose Cuttings.**—What is the treatment of Rose cuttings from the moment of cutting till the cutting is rooted?—F. J. L.

2880.—**Propagating Azaleas.**—How and when are hardy Ghent Azaleas propagated?—A. RUMMUN.

2881.—**Saving Stock Seed.**—Can any reader inform me of the proper way to collect and preserve the seeds from German Stocks? Mine this year have made remarkable bloom, and I should like to preserve seeds from the best of them.—AMATEUR.

2882.—**Soil and Treatment of Orchids.**—Will anyone give treatment and full description of soil, &c., necessary for the following Orchids: Cypripedium insigne, Odontoglossum Fairfaxianum, Dendrobium nobile, Bletia hyacintha?—ERIN.

2883.—**Trees for Front Garden.**—Will any one inform me what trees are most suitable for the forecourt of a house 5 ft. deep, facing west? I want some which will not spread their roots out far, and grow green and bushy. The centre under the window I wish for flowers or evergreens.—W. J.

2884.—**Vines in Pots.**—I have six seedling Vines, two years old, in 6-in. pots, full of roots, and 18 in. high. Will any one help me with information how I should proceed to grow and fruit them in pots? I have a greenhouse with a flue.—ENQUIRER.

2885.—**Heliotropes and Verbenas.**—Will some reader kindly tell a subscriber of GARDENING ILLUSTRATED the best method of propagating Verbenas and Heliotropes, and the right time? also the soil best suited for them?—P. E. U.

2886.—**Heating Greenhouse.**—I have a greenhouse 18 ft. by 9 ft. Can any one tell me if a paraffin lamp would be sufficient to heat it in winter?—FINCHLEY.

2887.—**Water Lilies in Bouquets.**—I should be glad to know the secret of keeping Water Lilies when cut from closing, so many used for table and other decorations which appear wide open at all times.—M.A.C.

2888.—**Night-scented Petunia.**—I have had a few seeds sent me marked Night scented Petunia. Not having seen or heard of such before, can any reader give me any information respecting it? also the best mode of growing it?—PETUNIA.

2889.—**Early Tomatoes in Greenhouse.**—Can any reader give instructions in the early culture of Tomatoes in a greenhouse (heated)? Is it better to sow the seed now and keep on growing through the winter? or from cuttings, and how to take them, and the best time?—KNOWLEDGE.

2890.—**Plants for Shady Situation.**—What plants will grow in a bed shaded by Beech trees, and with only morning sun?—E. W. B.

2891.—**Pansies in Pots.**—Will some one inform me how to grow Pansies in pots?—R. B.

2892.—**Maréchal Niel not Blooming.**—I have a Maréchal Niel Rose; aspect south and south-east, has the sun from early rise to about noon, has made a large quantity of wood, been planted five years, and yet it has never had a Rose on it. What can I do with it to make it flower?—C. W.

2893.—**Saving Cabbage Seed.**—I have a Cabbage run to seed, but do not know whether the seed will be any good. Will some one tell me the proper way to act with it?—C. F.

2894.—**Plants for Baskets in Winter.**—I want to fill some small circular tins, intended to be fitted into baskets, with any plants that would look nice in November and December; which would be best? What kind of Moss would look fresh and green then? Is there any plant of a neat habit that would flower at that time? and any that could be trained over the handle?—H. H. H.

2895.—**Vallota purpurea in Windows.**—My best thanks to "J. C. B." for his reply to my query, but will he or some other correspondent kindly inform me if I may repot my Vallotas at once, as there are two good-sized bulbs in one small pot, and I find the roots are growing through? also, if they would be better separately? and what is the proper course to pursue with the tiny bulbs or offsets produced on the sides of the larger ones? I have been taking them off and planting round the margin of the pot, and have now about eight of them, and should be glad to know if my treatment of them is right?—A. A. STAFFORD.

2896.—**Best Time to Buy Hay and Grain.**—Will some readers tell me from experience which is the cheapest time for laying in a stock of Oats, Barley, Maize, and Hay? I have a large granary.—CONSTANT READER.

2897.—**Saxifrages Dying off.**—I have lately lost several large plants of Saxifrage, among others S. Wallacei and S. atro-purpureus, each of them forming cushions 15 in. or 18 in. in diameter. They had grown rapidly and flowered freely all the summer. A few weeks since some of the tufts began to wither, and came away with a slight pull. The mischief spread rapidly until the whole plant was gone. They were growing on a raised bed formed of good soil over 1 ft. or more of broken stones and bricks, with the surface thickly covered with large stones partially buried, between which they were planted. Can any one suggest what is the probable cause of their suddenly going in this way, and how to preserve the remainder from a like fate? I lifted one of them and examined the roots, but could not discover anything wrong.—W. D.

2898.—**Storing Potatoes.**—Will some reader kindly enlighten me as to the best mode of saving Potatoes, of which I have a stock sufficient to last me a year? My appliances are (1st) a large attic loft at the top of the house, not frost-proof, (2nd) a cupboard under the stairs, (3rd) a shed in the garden. Ought they to be kept in bags or loose?—CHAMPION.

2899.—**Flowers for Window.**—I have a large bow window which I am about to utilise for flowers; what would be the best flowers to select for blooming through the next six months? I have a cold frame in which to raise seed, but fear it is too late this season.—E. M. H.

2900.—**Law Respecting Greenhouses.**—As the district surveyors have been very busy interfering with the erection of the above in my neighbourhood, I should

be glad if some one would state what really is the law on the subject. I had intended erecting a portable greenhouse, but if they can interfere, of course I shall not do so.—E. M. H.

2901.—**Mezereon Daphne.**—Can any one tell me how to raise this? If from the berries, when should they be gathered and when sown? If from cuttings, when should they be taken? what kind of soil and situation?—TANNEBERG.

2902.—**Eucalyptus in Winter.**—I brought six plants of Eucalyptus globulus about 1 ft. high from the south of France eighteen months ago. Four I planted out in March last year, and they speedily succumbed to a hard frost we had that month. The other two I planted out in June and repotted them in October. They were again planted out last June, and one of them is now about 12 ft. high; the other not more than 6 ft. Can any one inform me if there is any chance of the larger one surviving the coming winter if left out? I am afraid it will have made too large roots for potting, and it would take up more space than I can afford in my greenhouse. Would matting be sufficient protection against an average winter?—W. D.

2903.—**Cropping a Garden.**—How can I best utilise part of a garden which has had a crop of Broad Beans and Peas? The soil is clay, and those mentioned above are the first crops that have been grown; it is near London and is in an open situation. I wish to grow some other vegetables, and wish to know how the ground is to be prepared, and what to grow.—M.

2904.—**Renovating a Garden.**—I have a garden of the following description lately come into my possession: It is surrounded by an 8-ft. wall; one side is shaded to an immense height by the trees of a park; the other side has very high Apple and Pear trees against the wall. The garden itself is studded by large unpruned fruit trees of all descriptions, so that on all sides it is very much shaded. The Gooseberry and Currant bushes have not been pruned for years, so that they are like wild Blackberry bushes. The soil is heavy clay, deep, but evidently pretty well drained. It is an old garden and thick with weeds, wild Convolvulus, Crowfoot, &c. It has not been cultivated for about five years. I want some hints as to how to begin to work at it, how to destroy the weeds, prune the fruit, what manure to use, and the best kind of crops for a shady place?—J. W. R.

2905.—**Geraniums and Fuchsias for Winter.** What Geranium or Fuchsia would flower before or about Christmas if I procured them now and looked well after them in window (south)?—A.

2906.—**Climbers for Trellises.**—Suggestions wanted for hardy creepers for the above. Roses do not seem to prosper; the trellis stands out along a garden walk.—J. L., *Ireland*.

2907.—**Lapageria rosea not Flowering.**—I have a healthy plant of the above; it is four or five years old, is planted in the border in a well-lighted and ventilated conservatory, has sent strong shoots to the roof, but never had a single bloom. Can any one suggest a remedy?—J. L.

2908.—**Slugs in Larders.**—Can any of your readers tell me how to rid a house of slugs? They crawl over the food in the larder, and we cannot trace them to their holes. I have had all the apertures round the floor stopped up and the walls washed with lime, but they appear to increase, and we cannot catch them, as they disappear before daylight.—A SANDY CAT.

2909.—**Maiden-hair Ferns.**—Will some one tell me if in a small Fernery the Maiden-hair refuses to flourish side by side with a common hardy Fern? I find that my Maiden-hair plants do so much better when placed in a pocket alone. Is this usually the case? or is there any other likely reason why some of them have withered during the last month?—J. B.

2910.—**Delphinium nudicaule.**—I should feel greatly obliged for some information on the cultivation and soil for Delphinium nudicaule. I have raised some from seed, and have just lifted one and find it is a minute tap-root or tuber, somewhat of the shape of the little French forcing Carrots. I cannot find any description of the plant or instructions, beyond planting them two or three together, as giving the best effect. I know they are hardy, but do not know whether they would stand the winter in a small state.—J. D.

2911.—**Mushrooms in Asparagus Beds.**—I have heard of Mushrooms growing spontaneously year after year in an Asparagus bed. Would it answer to plant the spawn in such beds? and if so, what would be the proper season?—M. W.

2912.—**Insects in Beans and Cabbages.**—What occasions "clubbing" in Cabbages, French Beans, &c.? and the cause of so many white maggots forming at the roots of the latter? Is there any remedy against these evils?—J. B. C.

2913.—**Wintering Cuttings and Ferns.**—Can any reader tell "A Novice" how to make a 2-light Cucumber frame available for preserving cuttings through the winter? The frame stands on a gravel path; it is too near the house to have a hotbed in it. Would plunging the pots in Cocoa-nut fibre answer? or is some kind of heat indispensable? My aim is simply to preserve the plants from frost. Also, would Ferns in pots live through the winter if plunged in the borders? and how deep must they be?—ALICE GRIMES.

2914.—**Mushrooms Infested with Maggots.**—I have a Mushroom bed made in an unused coach-house. About a month ago they first made their appearance, and I gathered from the bed nearly 3 lb. of very fine Mushrooms. Since then they have not come up so plentifully, and after they have been up a day or two they have fallen to pieces on the bed, and have appeared quite decayed and wet. A few days ago I gathered 2 lb. more, and when breaking them in two I found the top or white part decayed and full of maggots like those we find in cheese. The smell, too, is so unpleasant, that I must throw them all away. They are very large, thick Mushrooms. Can any correspondent tell me the cause of their decay? or what I should do to prevent further waste?—CREEPING JENNY.

2915.—**Incarvillea sinensis and Loasa Herberti.**—Seeing these recommended as greenhouse creepers, will some one give me instructions for raising them and for their general cultivation? also inform me as to their value for that purpose?—PHLOX

2916.—**Keeping Flowers in a Cut State.**—Can any one inform me how to keep cut flowers, such as Dahlias, Gladiolus, and Hollyhocks, fresh? Should the stems be placed in water? and how often should the water be changed? also the best situation for them? Would they do in a dark, moist cupboard, with a little air? or in a light, shady situation with plenty of air?—SEVEN SISTERS.

2917.—**Striking Magnolias.**—Has any one succeeded in striking slips of these in the open ground? If so, under what conditions?—A. COVENTRY.

2918.—**Plants for Small Basin.**—I have a small fountain, and should very much like to grow a few plants in the basin, but they must be in pots. I have two pots of Creeping Jenny; it grows and looks nice and green, but does not flower, and is growing rather weak. I think, perhaps, it is rather too close for it. I have asked several gardeners for Cape Pondweed, but cannot get it What plants would be most suitable? They must be of dwarf habit. The house is heated in winter.—W. H.

2919.—**Rhubarb for Wine Making.**—I have about an acre of land to spare. I am thinking of growing Rhubarb for wine making; what sort would be best for the purpose? and when is the best time for planting?—J. S. L.

2920.—**Verbenas from Seed.**—Which is the best way to raise Verbenas from seed? also what soil, situation, and treatment are required?—AMATEUR.

2921.—**Fuchsias and Zonal Geraniums.**—Will some one kindly name a dozen of each of the above, half the number doubles and the other singles?—STOKE-ON-TRENT.

2922.—**Mimulus cupreus, &c.**—Would Mimulus cupreus (scarlet) be a suitable plant to bed along with Marshall's Musk and Lobelia? if so, would it succeed raised from seed in the spring? or if any more suitable plant (scarlet) please name it and oblige.—G. G.

2923.—**Gardening on Clayey Soil.**—My front garden lies in a sheltered situation facing about south-west, and the soil is rather of a clayey nature. I am told that I should succeed with Roses if I could but obtain the proper varieties. I shall be greatly obliged by hints or instructions. I should like to have a climber up the side of the house, and the John Hopper variety has been mentioned to me as a good sort, but I have no knowledge of its habits or growth. My back garden was (until I became tenant of the premises, seven weeks ago) a waste covered with rough Grass. I have had the sods (beneath which I discovered that there is a few inches below the surface a lot of clay) turned over in the hope that they will rot by next spring. I have planted a few Cauliflowers and Winter Cabbage, Spinach, Peas, Turnips, and Celery (using good manure); they seem to be doing reasonably well, except the Cabbages, which are now being attacked by an insect looking like the green fly, which gets inside the tender leaves and makes them curl and wither. I hope next season to do better with my garden, and have thought that I had better have (a few weeks further on) several loads of soil laid on to make a respectable bed. I have already taken out a small load of clay and thrown it away as worthless. I shall be glad of any advice on the subject.—CROFT.

THE HOUSEHOLD.

How to Pickle Eggs—In answer to W. Brown's inquiry in GARDENING of August 21 (No. 76), I send the following recipe: Boil five or six dozen eggs in a capacious saucepan until they become quite hard; then after removing the shells lay them carefully in large-mouthed jars, and pour over them scalding vinegar well seasoned with whole pepper, allspice, a few races of ginger, and a few cloves of garlic. When cold bung them down closely, and in a month they will be fit for use.—M. E. I.

—— Take 1 quart of strong brown vinegar and simmer in a saucepan over a slow fire for half-an-hour; put in 1 oz. ginger race, 1 oz. whole mustard seed, 1 oz. whole black pepper, 6 cloves of garlic. Have ready forty-eight hard-boiled eggs. As this is the important point please observe that the eggs are put in cold water set on a very brisk fire and kept on for at least fifteen minutes after the water boils; then drop them immediately into the coldest spring water. This separates the shells from the whites, and renders the removal of the inner skin easy. Lay the shelled eggs in circles in large earthenware jars, pour the pickle over them as soon as it has boiled sufficiently, and when quite cold bung down. They will be fit to use in a month, but will keep good six months.—A. B. T.

Preserving Eggs.—A much more satisfactory way of preserving eggs than keeping them in lime water is to rub them when warm from the nest with grease made of white wax and good salad oil. Eggs thus preserved may be used six months after. They should not be packed in bran.—M. C.

—— Take the ashes from the grate and put them through a fine riddle, then cover the bottom of any box you have with them, say 2 in. deep; place the eggs (fresh) therein, large end downwards, as close as you like, but not to touch each other; cover them with more ashes 2 in. deep, and so on till full. If they are put in a dry place they will keep twelve months.

Preserving Vegetable Marrows.—Can any reader tell me how to preserve Vegetable Marrows to imitate preserved ginger.—A. C. T.

Preserving Green Peas.—Can any of your readers inform me of a way to preserve green Peas for winter use? I keep Scarlet Runners by simply putting them in a pan with plenty of salt; when I want to use them I soak them all night in water and cook them as fresh-picked ones.—QUISITANT.

Pot Pourri.—Will any one kindly inform me how to make pot pourri as our great grandmothers used, so that it may be sweet for years?—F. F.

BEES.

The Value of Bees.—A great bee master, the Rev. M. Sauppe, of Lückendorf, makes the following calculation, intended to prove the eminent agricultural and economical importance of the rearing of bees:—Of each of the 17,000 hives to be met with in Saxony, 10,000 bees fly out per diem—equal to 170 millions—each bee four times, equal to 680 millions, or, in 100 days, equal to 680,000 millions. Each bee before flying homeward, visits fifty flowers, therefore the whole assemblage has visited 3,400,000 millions of flowers. If out of the ten only one flower has become fertilised, 340,000 millions of fertilised flowers would be the result. Supposing the reward for the fertilisation of 5000 flowers to be one German pfennig, the united bees of Saxony have obtained per annum a sum of 68 million pfennige—680,000 marks (£34,000 sterling). Each hive represents in this way a value of £2 sterling.

Bee Keeping.—If "W. W." will visit some of the bee shows which are held in various parts of the country, and ask any bee-keeper he meets there to coach him up in hives, and he will get more knowledge in half-an-hour than he can get by reading for days. Let him enter the manipulating tent, and he will see the operation of "driving" bees from straw hives, which will teach him how to force his bees to swarm at his will, instead of having to watch and wait their wills. If he lives in the neighbourhood of London, he cannot do better than visit the shows of the British Bee-keepers' Association, held at the Horticultural Gardens, South Kensington. He will see exhibited there hundreds of hives of all kinds and makes, and all kinds of apiarian appliances, honey, bees of various races, &c., and will be much interested. Let him ask some one to show him an improved Woodbury hive, and let him see the bees from the Holy Land, and from Cyprus, and from Italy.—APIS.

HOME PETS.

Keeping a Tortoise.—I have kept a tortoise twelve years. It buries itself the first week in November, and reappears the first week in March. It will then only eat Dandelion flowers and Buttercups, but its appetite improves, and it has now devoured several large Lettuces, also Sow Thistles. Nothing more is needed, but it is necessary to watch that he does not get out of the garden, which, in the summer, he is always trying to do.—P. S. L.

—— We have had a tortoise many years in perfect health. He requires to be put in a garden where he can have a good supply of short Grass and Clover. In spring he eats Dandelion blossoms and Buttercups, also Lettuces. In summer he is so fond of fruit, such as Strawberries, Currants, or Raspberries, that he will follow us round the garden for it. He goes down about September or October, generally choosing a sheltered spot under a shrub, and remains until March or April.—A. N.

Treatment of Canaries.—Would some experienced reader of GARDENING give a full account of the treatment of canaries?—BIRD FANCIER.

Tortoise Eating Insects.—*Bath.*—We do not believe that a tortoise either eats slugs or woodlice, but lives entirely on fruit and vegetables.

REGISTERED FOR TRANSMISSION ABROAD.

JAPAN ANEMONES.

THE White Anemone (A. japonica alba) which we now illustrate is supposed to have originated from a sport of the better-known rose-flowered A. japonica. It is, however, probable that the white variety is the original and the rose-coloured one the sport, for never have we seen the latter grow with anything like the vigour of the white kind, and it appears, moreover, to be of a weaker constitution altogether. Both are, however, worth culture, but the white kind should always be cultivated both in large and small gardens. It flourishes in any ordinary garden soil, either in the shade or in the sun; even under trees it flowers well, although in such a position the plant becomes more lanky and less attractive in habit.

THE WHITE JAPAN ANEMONE, 3 FT. HIGH.

When well grown in an open situation and in warm sandy soil, it is a really charming plant, its flowers being large, handsome in form, and very effective. Not only is this Anemone valuable in beds and borders, but it is equally desirable for pot culture, and when placed in a cool greenhouse it is safe from winds, and lasts in bloom till a very late period. In order to grow either kind well, they require a deep rich soil and plenty of moisture while renewing their foliage, as otherwise they are subject to the attacks of red spider. The great point is starting them fairly at first, and then leaving them alone ever after, as old-established clumps are always the strongest and best. Most kinds of herbaceous plants are greatly improved by being taken up now and then and divided; but not so these, as their nature is to form large roots low down, and it is from the young feeders on these they draw their supplies. In hot dry weather a mulching placed about them, and a soaking or two of liquid manure is of great assistance to them, as it enables them to push up their flower-spikes freely, and make fresh

White Japan Anemone—showing habit of plant.

crowns around their base. Those who wish to begin with them in pots will, find this a good time to lift any of the young side-shoots that spring up so freely from old plants. If these are dug out of the ground with care, and, after being potted, are kept close for a week or so in a cold moist frame, they will be found to have taken well hold of the soil, and in a condition to bear the air and exposure. Although perfectly hardy, when grown in pots it is always advisable to keep them plunged in a position secure from frost, as it should be borne in mind that a plant having its roots in such a small body of soil is very differently circumstanced to others in the open ground, where, deep-rooted as they there are, they cannot be injured. To obtain fine strong pot specimens requires some years of rich feeding, but so serviceable are they, that they are worth more than the care and attention which their cultivation entails.

For those who do not know this lovely flower we would describe it as being like a very large Wood Anemone, growing from 3 ft. to 4 ft. high, and bearing from a dozen to twenty flowers on each stalk. As regards purity and beauty, it is fit for a bride's bouquet. For room decoration it is also exceedingly useful, either in pots or in the shape of cut blooms. The latter last fully a week in water if cut when freshly opened. The plant is perfectly hardy, needs no skilful cultivation, and is cheap. In mild seasons this Anemone blooms from early in August till the end of October. We may add that there is a supposed robust variety of the White Anemone known by the name of A. Honorine Joubert, but it is no variety at all, it being only Anemone japonica alba well grown. We have seen fine plants of Japanese Anemones growing under the most unfavourable conditions in the smoke of London, proving it to be a good town plant. The flowers from which our illustration was prepared were gathered from strong plants in Messrs. Osborn & Son's nursery at Fulham.

This Anemone is easily increased by means of root cuttings. In November dig up a plant from the open ground, and cut up the roots into pieces 1½ in. long. Well drain some pans about 3 in. deep, and fill them with finely-sifted soil, consisting of loam, leaf-mould, and sand, to within ½ in. of the rims; press all down gently, make the surface level, lay down pieces of root all over it, and cover up to the rim; give a good watering and place them on a shelf in the propagating house. In about three weeks they will push through the soil, and in another fortnight will be ready for potting off. They ought to be kept gently moving till they can be gradually hardened off in a cold frame. Plant them out in March, take them up and pot them in September, and transfer them to the greenhouse as required, *i.e.*, if wanted for indoor decoration.

FRUIT.

Gathering Apples and Pears.—In keeping these sound for the longest period much depends on the care with which they are gathered, and also on each kind being gathered at the right moment. Every one is capable of gathering carefully, but a certain amount of practical experience is indispensable as regards the second requisite. Imagine Williams' Bon Chrétien Pear and a Winter Nelis gathered at the same time! yet such I have known to have been done. It is well known that Apples or Pears gathered before growth is complete shrivel and dry up prematurely, or, if this does not happen, they are "sticky," and never so thoroughly mature as to be usable. More Pears are made bad than are bad naturally through this one cause of premature harvesting; therefore I would recommend grumblers about "sticky" Pears to this season leave them longer on the trees. Unfortunately, no one rule is applicable to every case as to when an Apple or Pear is fit to gather, as soil, position, exposure, and shelter have much to do with the season of fitness to gather. But as a sort of guide to the inexperienced who may be in uncertainty, I would say, if the fruit be very gently moved upwards and part readily, without the slightest pull, from the tree, then it may safely be gathered. Another good test is to cut open a fruit, and if the seeds or pips be quite brown or black, then the crop is fit to gather. Another test, in the case of the earlier ripening kinds more particularly, is when birds or wasps begin to attack them; these depredators are too good judges to make mistakes. Apple gathering in some parts is looked upon as a very ordinary operation, capable of being performed by anybody and anyhow, a plan which might answer if the fruits are to be ground into cider or used forthwith, but if they are to be kept in sound condition for any length of time, too much care cannot be bestowed on gathering them, as the slightest bruise induces decay; and the same remark is applicable to Pears, with the addition that, if possible, even more care should be taken with them. The manner of storing in fruit rooms is also of importance. If space can be spared, the fruit should be put in single layers only, and certainly in no case should it be more than two layers deep. The room ought previously to have been well cleansed and dried, and for the first two or three weeks after the fruit is gathered all the air possible should be given, as when first housed a moisture is given off by the fruit, which, if not driven out by free ventilation, lays the foundation for decay. Specky, bird-pecked, or wasp-eaten fruit should not be put in the same room with that which is sound. If it cannot be used at once, better throw it away than allow the fungus which it engenders to spread to the fruit which is good.—W. H.

Prolific Fig.—This is a name very appropriately given to a Fig now being largely grown in Messrs. Osborn's nursery at Fulham. The plants are grown in 6-in. and 8-in. pots in an ordinary span-roofed greenhouse, and at the present time many of the plants bear from nine to a dozen fine fruits which will ripen in the course of the autumn. The Fig is one of the most delicious of fruits, and any one may grow it. The kind mentioned above is well worthy the attention of those who are fond of Figs, but who have but little space under glass or in the open air in which to grow them.

Selecting Pear Trees for Planting.—One seldom looks over a new plantation of Pears without finding a number of varieties that are in every way thriving and giving promise of good results, while an equal number is by no means satisfactory. As a rule, the aim seems to be to have as many varieties as possible, some of which might succeed on a wall, but in any other way are useless, and others are not suited to the locality. The season for planting being now at hand, I would recommend the selection of varieties that would succeed in the district in which the new plantation is to be made, for what can be more vexatious than spending time and labour on the culture of a given number of trees the produce of one-half of which turns out to be useless? Few fruits, in fact, are more variable than the Pear, or are more capricious under haphazard culture. The best way of converting vigorous, but unfruitful Pear trees, or such as produce fruit of inferior quality, into remunerative ones, is to head them down while the sap is dormant, and to re-graft on all the extremities as soon as it begins to flow in spring with some tried sort from the neighbourhood. The double grafting will be certain to induce fertility, and in a few years the produce will exceed what it is possible to obtain by any less radical measures.—J. G.

Raspberries on Light Soils.—The Raspberry is difficult to manage on light soils, especially where the climate is very changeable; under such circumstances the Raspberry requires a deep moist soil, a shady situation, and plenty of water during the growing season, *i.e.*, while the young fruit-bearing canes are being formed. Where the ground is gravelly or light, it may be improved by removing a portion of the natural soil and adding fresh compost, such as decomposed vegetable matter, mixed with the refuse collected from the potting bench, or other similar material. A crop of Cabbages planted between our rows of Raspberries was removed early last month; the old canes were cut away, and the young ones reduced to from three to four to each stool. The surface of the soil was then loosely forked over and a heavy mulching of horse manure, from the stable yard, was spread over it, and in addition to all this the ground has been thoroughly soaked two or three times since with liquid manure. The result is, the canes are growing apace and thickening, and by the end of the season they will be good for this locality. Too much importance cannot be attached to the position allotted to Raspberries where the soil and climate are naturally unfavourable. I have never seen such Raspberry canes as I once saw in the north of Scotland in a deep light soil in a low-lying district naturally shaded by trees from the fierce rays of the sun. Conditions such as these do not, however, exist in every garden, but they may to some extent be imitated. A cool position, surface mulching, and copious supplies of liquid manure will go far towards counteracting unfavourable con-

ditions both of soil and climate.—W. H., *Liverpool.*

Coe's Late Red Plum.—I find this to be a useful variety when very late Plums for culinary purposes are required, and when grown and ripened on a wall it is even good for dessert. If netted and kept secure from the attacks of insects it will hang very late on the trees.—R. O. O.

VEGETABLES.

GROWING MUSHROOMS.

Mushroom Houses. — It frequently happens that an outbuilding of any description that can be spared for the purpose will answer as well or better for the growth of this vegetable than houses that are built expressly for it. For amateurs to succeed in the cultivation of Mushrooms it is necessary to reflect a little upon the natural conditions of their growth. As every one connected with rural affairs is without doubt aware, Mushrooms grown in the open fields are not equally plentiful every year. In seasons when they are the most abundant it will invariably be found that it is when the earth has been warmed to a considerable extent by a long continuance of hot, dry weather before August, with a copious rainfall during that month; this produces in the heated ground something almost approaching to fermentation, as will easily be ascertained by plunging the hand during a hot season in loose earth a day or two after it has been well moistened by rain. The heat and moisture thus combined start the spawn (which in some land is always present in quantity) into action, and should the atmosphere be still and moist and cloudy weather follow, then there is an abundance of Mushrooms out-of-doors. This at once points to the conditions necessary to be observed when they are to be grown in houses. From the present time to the close of the year they may be produced with the greatest facility and certainty; they can be grown in a very small building, but the larger the internal space, within reasonable limits, the less fluctuations there will be in the temperature, especially in changeable weather—a condition of great importance to success. An empty stable, or any similar place on the ground-floor, will generally be found to answer; if there be an apartment above, all the better, and a thatched roof is much to be preferred to either slate or tile, for the variations in the weather will have less influence upon the internal temperature than if the roof be covered with slates or tiles.

Making the Beds.—Manure in quantity proportionate to the space at command, or the size of the bed to be made, should at once be procured; this may consist of from a few wheelbarrowsful up to an ordinary cart-load or more; let it be fresh, and such as has not been saturated by rain, or has previously fermented to any considerable extent. Shake out all the long litter, leaving nothing but the droppings and short bits of straw; throw it together in a heap, either in an open shed or in the place where the Mushrooms are to be grown; do not allow it to remain so long as to ferment violently—to avoid which turn it over two or three times at intervals of four or five days; by this time it will have discharged the superabundant moisture, and can be at once made up. The bed or beds may be made altogether on the ground-floor or can be constructed in the form of wide wooden shelves, two or three above each other, with spaces between of 3 ft. or 4 ft.; but where there is room I should recommend their being made altogether on the ground-floor. Shake the manure well together, and beat it solid with the fork as the work proceeds to the thickness of about 1 ft., making the whole smooth with the back of the spade.

Spawning.—Insert a thermometer in the middle of the bed, and as soon as the temperature falls a few degrees under 80° put in the spawn, which should previously have been broken into pieces about the size of a small egg, and thrust in just below the surface 8 in. or 10 in. apart. It will be safer not to soil the bed for a few days until the heat appears to be declining; the depth of soil used varies considerably with different cultivators, some using several inches, others being equally successful with only a couple. I have generally found, when the greater depth is laid on, that the beds are longer in coming into bearing, as it takes more time for the spawn to run. The soil (any ordinary loam) must be of a medium moisture, neither too dry, nor so wet as to be adhesive; beat it quite firm, and cover at once with dry hay.

Watering.—In the course of a month the Mushrooms should make their appearance—about which time examine the bed, and if it be too dry, which will be indicated by the buttons not swelling freely, give it a moderate moistening with tepid water applied through a rosed can, after which replace the hay on the surface. When the bed has been in bearing for some weeks and the growth of the crop begins to slacken, soak it moderately with tepid water, which will often have the effect of inducing a further production. Of course I am supposing that the building is not provided with any heating medium. As the autumn months advance other Mushroom beds may be made up, and the warmth given off by the manure for these will keep up the requisite temperature for the growth of the Mushrooms. Towards the close of the year, when the weather becomes cooler, a little more covering may be used to the beds; the door in all cases should be kept shut, and any windows or other apertures through which the external air can get in quite closed.—T. P.

Potato Crop.—I have just finished taking up my second early Potatoes. On the whole, the crop has been a capital one, and generally pretty free from disease, especially Excelsior, Beauty of Hebron, and last, but by no means least, Snowflake. Out of some thirteen of the very best varieties grown in a dry, sandy loam from seed obtained from first-class houses, I find that the last-named of the above trio is, with the exception of International, the heaviest cropper and handsomest tuber of any second early variety in my garden; and, what is of far greater importance to the general grower, its cooking and keeping properties are immeasurably superior to that variety. In fact, with me it is only second in these respects to Magnum Bonum, which up to the present, and for the past three seasons, has entirely escaped the disease, which is more than I can say on behalf of either Woodstock Kidney or Reading Abbey, although grown in the same plot—aye, and in the same row—with Magnum Bonum, and which, moreover, had the extra advantages of soot and wood ashes.—Subscriber, *Towcester.*

Potato Notes.—Alpha (Pringle's) spread thinly on a loft, and lightly covered with straw, not moved all the winter, budded freely—buds some 3 in. long, with green leaves, when the Potatoes were planted, on the 28th April, in a south border. On the 28th June a luxuriant healthy growth, and, when dug, nice Potatoes, of size up to a hen's egg. Beauty of Hebron, planted on 13th February, produced on the 26th May Potatoes as large as hen's eggs. The stalks replanted when dug on the 28th June had a lot of small Potatoes, which would evidently have given a second crop if left in the ground. The old sets of this Potato, after the crop was dug in June, sent out new buds, as if never planted. Large mealy delicious Potatoes were used of this sort on the 25th of June. Extra Early Vermont, planted the 4th of March, were covered with white blossoms and the foliage strong and healthy, with large Potatoes and a heavy crop.—Wm. Johnston, *Ballykilbeg, Co. Down.*

Radishes for Winter.—For autumn and winter use these must be sown at intervals, from the beginning of August till the middle of September. To produce a crop fit for table at Christmas they must be sown in a frame the first week in October—say, a frame that has been used for Cucumbers or Melons—which should be filled within several inches of the glass with light soil; sow the seed not too thickly, protect from birds, and give plenty of air when the weather is mild. Protect from frost by covering and mulching round the frame, and there will be plenty of Radishes for salad on Christmas Day. For sowing in the open ground in summer and autumn I prefer the white Turnip, and Wood's Short-topped and French Breakfast for the frames.—H. O.

THE HARDY CACTUS.
(OPUNTIA RAFFINESQUIANA.)

Where variety is sought for this plant should certainly be grown. It is so entirely distinct from every other kind of hardy plant, as to render its presence in a garden highly desirable. Its perfect hardiness is beyond all question, as I possess a plant which has braved without flinching the rigours of ten successive winters. Excessive cold it does not mind, but stagnant moisture at the root will soon carry it off; therefore, plant it in a high and dry position, where it may catch every ray of sun in the summer, and where superfluous moisture may easily drain away. It is strange that this interesting plant should be so little known in English gardens; it is only within the last few years that growers in this country have taken it in hand. It is by no means a new plant to European gardens, having been for many years in general cultivation in Germany, where I have seen specimens some 6 ft. across, completely carpeting the surface-soil with their curious fleshy stems and producing a quantity of handsome bright yellow flowers. In this stage of development it is very interesting, presenting a remarkably distinct, quaint, and ornamental appearance. Those who possess a rockery will have no difficulty in affording this plant the conditions indispensable to its welfare, as if planted in the sunniest and driest place it will be sure to thrive. Where such a suitable situation does not already exist, it is

Hardy Cactus (Opuntia raffinesquiana).

very easy to form a raised mound of earth and stones on which to plant it. The soil should be free and sandy, mixing with it, in order to insure porosity, some brick rubbish, river sand, or mortar rubbish. Snails and slugs are extremely fond of this plant, and will in the spring, and even in mild winters, completely destroy it if not prevented. A liberal dressing of soot will keep these pests at a distance, and will impart luxuriance to the plants, for although the Cactus family object to manure in the soil, they fully appreciate a top-dressing of some concentrated manure, soot, or guano. The propagation of the hardy Cactus is easily effected. The cutting, consisting of a single joint, is placed in very sandy soil, placing the pot containing it in a sunny, airy situation under glass, and watering very sparingly. In a short time it will form roots, and will then commence to push out several young shoots, which in their turn may be taken off.

J. Cornhill.

The Smaller Scented Water Lily (Nymphæa odorata minor).—This may be grown in any vessel if it be of sufficient depth and width to allow room for the full development of the leaves. The soil, which should be laid at the bottom from 4 in. to 6 in. in depth, should consist of one part fibry loam, half part well decomposed leaf-mould, and half part river sand and gravel. The vessel should be quite filled, and should be made to overflow daily by watering with a fine-rosed watering-pot, as this removes all floating green matter. A layer of fine gravel, spar, or similar material should be laid on the surface of the soil, in order to keep it from mixing with the water.—W. G.

Sunflowers.—These are generally regarded as suitable only for cottagers or for gardens to which little attention is given. As ornamental plants they are, however, not to be despised, their robust growth and commanding aspect rendering them suitable for many situations where plants of smaller growth would be quite lost. If placed where protection is afforded from high winds, and allowed sufficient space,

they assume a somewhat dense, branching habit; and when covered with bloom present a very distinct, and by no means unattractive appearance. On no account should more than one plant be put in a place. Crowding Sunflowers destroys their distinctive characteristics. The double Sunflower (Helianthus multiflorus fl.-pl.) is a fine perennial, which is very effective when planted in large masses along with Dahlias, Hollyhocks, Tritomas, or other tall-flowering plants. It looks extremely well, too, in shrubbery borders, or in mixed beds in which bold and striking colours are desired.—G.

Tropæolum Hunteri.—This is a dwarf Tropæolum of the compactum type. It is singularly dwarf in growth, has leaves scarcely larger than a shilling, and bears numbers of small bright scarlet flowers. It is well adapted for small beds and moist districts, as in the wettest weather it does not make a very profuse growth. Like all dwarf bedding Tropæolums, it should be raised from cuttings to keep it true and dwarf, as all the compactum section have a tendency to run out when raised from seed.—D.

Foxgloves and Ferns.—There is no mixture superior to these for effect. The long spikes of brilliant colour resting on verdant Fern fronds, with now and then a fine leaf towering up among the coloured spikes, are inimitable. The two also agree well together if neither be planted so thickly as to predominate over and smother the other.—D. T.

Sweet Peas for Furnishing Cut Bloom.—Blooms of Sweet Peas are universal favourites, and one great advantage in growing Sweet Peas for this purpose is that the oftener the expanded blooms are gathered the longer the plants continue to produce them. By sowing early in November we have had them in full flower in May, and with attention to mulching, watering, and gathering every expanded flower as it is ready, we have had plenty of blossoms the whole season.—G.

Two Useful Annuals.—A gay effect has been produced in the herbaceous borders here by alternate tufts of the richly-coloured Convolvulus minor and the Crimson Flax (Linum grandiflorum). These were sown in the borders early in spring, and thinned out to a few of the strongest plants. Hardy annuals such as these when thus treated produce most beautiful effects not excelled by Pelargoniums and other tender plants that require wintering under glass.—A., *Sussex*.

The Neapolitan Violet.—Winter is fast approaching, and the season for growing winter-flowering plants will soon be over. Neapolitan Violets suffer much from drought and red spider, and they must, therefore, be well looked after till the end of September, especially as regards watering. If the soil and situation chosen for them be suitable and good, crowns selected and planted out in spring will require very little attention beyond watering and keeping them free from weeds and runners; but if extra fine crowns and flowers be required, they will need greater care. The best plan is to confine the plants in spring to a single crown, selecting such as are strongest and best; prepare a border facing the north with some fresh loam and rotten manure, and plant the crowns out on it 9 in. apart. Wireworms and slugs are two of the greatest pests which Violets have. Therefore, in using fresh loam it should be well looked over, so as to pick out all the wireworms; a little soot put in it will tend to keep down slugs. Red spider is also very troublesome to Violets, but a sprinkling twice or thrice a week with water will keep it in check. A mixture of soot and sulphur is also a good remedy for this pest, but it should be syringed off afterwards, well washing the under sides of the leaves. Sometimes this Violet will grow very weakly, and the leaves become yellow, as if attacked by red spider. If a plant in this condition be lifted it will be found that the cause of the disaster is in the soil; the roots will be seen to have turned black, and, at the same time, no sign of blight will be found on the plants. Lime-water applied to such plants will often restore them to health. This disease seldom attacks them, except in wet seasons. This season let the runners be all taken off carefully; pick all the yellow or bad under foliage, so as to keep the plants free from slugs; hoe among them once a fortnight, so as to keep the ground fresh, and allow the rain to penetrate to the roots. Water once a week with soot and cow-manure water, in which a few sheep droppings have been steeped. Mix them in a large tub, putting about 2 quarts to 4 gallons of water; with this water the plants every other day during hot weather; but if rains come they only require a little manure water about once a week till the time of transplanting has arrived. If Violets are required to be in flower early in December, they should be lifted and planted in their winter quarters earlier than if they are to flower in spring.—H. G.

Two Good Carnations.—In a large collection of Tree Carnations grown in pots I noted two which ought to occupy a prominent place in every collection. One named Mons. Baldwin is a tall grower, and bears very large, well-formed, bright crimson flowers, which last on the plants in good condition for two or three weeks. Garibaldi is the name of the other; it is a dwarfer grower, but an equally abundant bloomer, its flowers being 3 in. across, and of a bright scarlet.—S.

Acanthuses in Bloom.—These are beginning to get a well-deserved place in our flower borders, and also occasionally in the sub-tropical garden. It, however, takes some time to get them thoroughly established, and hence we do not as yet often see them at their best. The large dark-leaved one, called A. latifolius, requires considerable time and good deep, rich soil before it attains its full size; it is then very effective. In some heavy cold clay soils these

Spiny Bear's-breech (Acanthus spinosus); showing habit of plant.

do not appear to flower freely. In warm open soils they bloom freely enough, and their flowers have a very distinct appearance from any others, and much quiet beauty. By the way, it is said that the firmly but delicately-chiselled beauty of the flowers and their surroundings led the Greek sculptors to adopt them as the original model of the celebrated Corinthian capital. Acanthus longifolius, A. latifolius, and A. spinosus are all kinds that flower well in good sandy loam, and which are much admired by all who see them. Where plants for indoors have to be largely provided, the Acanthus latifolius and mollis will also be found to be most useful, not only on account of their beautiful green foliage fitting them so well for large vases, but from the fact that they retain their health and vigour, and continue to produce fresh foliage in positions so imperfectly lighted and ventilated, that scarcely any other plant would exist for any length of time.—J. G.

Tyerman's Groundsel (Senecio pulcher).—This fine garden plant now flowers in London nurseries. It is a stately species, the flowers of which are fully 2½ in. in diameter, and of a rich crimson-purple colour with a yellow disc. The plant attains a height of from 15 in. to 18 in., the flower-stem being branched. It is not an annual, as was at one time supposed, and as the seed rarely ripens in this country, the period of blooming being late, it may be useful to know that it is readily increased by means of root-cuttings.—B.

Phlox Drummondi a Continuous Flowerer.—Not the least amongst the many good properties possessed by this beautiful annual is that of its flowering continuously late in autumn; when most of the occupants of the summer flower beds begin to fade this is even more floriferous than in the height of summer.—J.

AUTUMN FLOWERS AND ANNUALS TO BLOOM IN SPRING.

There are plenty of beautiful flowering plants which bloom freely and naturally in autumn but they require to be thoroughly established, and should, therefore, be planted early in spring and carefully tended during the summer months. Let us take, for instance, the herbaceous Phlox, the colours of which are both chaste and brilliant. They should be planted in rich soil in March, and should be mulched and well supplied with water throughout the growing season. The same may be said of the Chrysanthemum, which requires generous treatment. Anemone japonica, of which both the white and red varieties should be grown, is a beautiful autumn-flowering plant, as is also the brilliant Lobelia fulgens. This latter plant should be planted in free light soil; sandy peat is the best material, as in this the roots are not so liable to decay. Then there are Rudbeckia Newmanni, a showy perennial with yellow flowers; Hydrangea paniculata grandiflora, flowers snowy white, lasting far into the autumn; various kinds of Michaelmas Daisies; the Golden Rod, Stokesia cyanea, and last, but not least, the beautiful family of Clematis, which last in beauty up to the close of the autumn. By means of the above-mentioned plants a garden may be made gay and interesting throughout the autumn months. Annuals for spring flowering should be sown at once. They may be sown where they are to bloom, which is the least trouble, but as they need full exposure to sun and air, they should be sown where they are not hemmed in by tall-growing plants. Choose, therefore, a piece of ground in an open, sunny situation, and fork it up, so that it may come into a nice free mellow condition; rake it perfectly level, and then sow in very shallow drills. If the weather is dry water the drills before sowing the seed, and sow thinly. Thin out the seedlings when up to 4 in. apart, so that they get robust, a point of the utmost importance, as they have to endure the vicissitudes of the winter months. By the commencement of October they should be placed in their permanent situations, planting them quite 9 in. apart, for it should be remembered that autumn-sown annuals attain much larger dimensions than those sown in spring, and consequently require much more space. A square foot is none too much for a spreading plant like the Nemophila, the beauty of which cannot be properly estimated unless thus treated. J. C.

What is the Use?—The following sensible note from an American contemporary may be read with profit by many of our readers who ask queries:—If "J. B. H.," of New Holland, Ohio, had signed his full name, he might long ago have had an answer by postal card—telling him that there were probably no Cashmere goats in the country.—There was nothing in the question that "J. B. H." need be ashamed of; even were he candidate for President, no capital could be made against him. What is the use of writing letters and omitting to sign them? The general fate of such is the waste-paper basket. If a letter is not of sufficient importance for the writer to sign it, it is of no sort of importance to us, and three cents may be saved if the writer puts it into his own waste-basket.

New Grass-cutter.—We have lately had the opportunity of seeing a handy little tool for cutting Grass where a machine is inconvenient or too costly. It is patented by Mr. Ridgway, 18, Market Place, Macclesfield, and so far as our experience of it goes it does its work satisfactorily; and if it proves durable, as it appears likely to do, it will doubtless command a large sale. An illustration will be found of it in our advt. columns.

Improving Lawns.—We have read with pleasure "J. D.'s" interesting notes on this subject. As to the varieties named by "J. D.," he is quite right as far as he goes. We find it advisable to add other fine-growing sorts, and such as are naturally inclined to tiller, especially when mown. It is to the careful selection of grasses possessing these desirable qualities that the close and springy nature of the lawns produced at the Paris Exhibition is attributed. With regard to turf, it is, as "J. D." remarks, very often carelessly chosen, and our experience is that so great

is the expense, trouble of after management, and coarse appearance of many lawns produced by turfing, seeding is becoming much more general, and the fact is, that if people would only seed more liberally, a more satisfactory result would be obtained in as short a time as with turfing. It is a very common error to suppose that grass seed will grow well, however sown, and however little attended to. But the fact is, it requires a very finely disintegrated seed-bed, and especially so the fine growing varieties recommended for lawns. The depth to which the seed should be covered is another important point, which is not sufficiently attended to. The looser the texture of the soil, the deeper may the seed be covered with impunity. But we consider the safest plan is to rake the seeds in very lightly, and give a good covering of old hotbed or some similar substance, which protects the seed from birds and sun, at the same time encouraging germination and growth.—Carter & Co.

Cure for Celery Blight.—Having been for some years troubled with Celery blight, the attacks of which are readily recognised by the leaves of the plant looking as if they had been scalded, I determined to seek a remedy which should either kill or cure. I directed my kitchen gardener to fill his 36-gallon water-barrow with sufficient water to dissolve two 1-lb. boxes of Gishurst Compound, mixing with it 1 lb. of Pooley's Tobacco Powder, and filling up the whole with boiling water, stirring all well together. The mixture, after being allowed to stand for some twenty-four hours, was used to water the affected Celery plants, a watering-can with a very fine rose being employed for the purpose. The plants having been well saturated with this mixture were then examined, and the grubs which had burrowed in the leaves were all found to be dead. The crop at the present moment looks most flourishing, the mixture having evidently acted not only as an insecticide, but as a fertiliser. About three weeks after I repeated the same treatment with another crop, with precisely the same results.—J. R.

RE-ISSUE OF PAXTON'S "FLOWER GARDEN."*

The re-issue of this old work, the first number of which is before us, we should say is both an unwise and unprofitable undertaking. It is too expensive and uninstructive to ever become popular, and the coloured plates are anything but good. In the face of the great amount of good work which remains to be done, and may be done by even those who only look at matters from a business point of view, it is not desirable that descriptions of plants which have been banished from our gardens as undesirable should be re-issued in the form of a new gardening work. The first number begins with two new plates, both hard, and poor, and crude in execution and colour as plates can be. The plate of Spiræa palmata is a dirty dull purple, the plant being of a fine bright crimson-red. No doubt succeeding numbers will contain old plants re-issued, and we hope with a better result than the present one. The editing is done by Mr. Baines, who, of course, is well acquainted with the cultural details of many plants, and is well able to describe the conditions under which they are most likely to succeed. The arrangement, however, is as puzzling as it well can be. On the first page we get a short description and some cultural hints on a genera of Orchids; next, we get similar information respecting a Spiræa; then, short botanical descriptions of an Aristolochia and another Orchid, a Cactus, a few words about a hardy plant; then we get to a rare Dracæna. Next, we come to a Berberis, then a few more common greenhouse and half-hardy plants, and a rare Anthurium, a line on a rare terrestrial Orchid, then more Berberries. We turn over leaf, and come to a mixture of hardy, and stove, and greenhouse plants, and another Anthurium, and presently another Spiræa, and another dose of half-hardy annuals, &c.; and, coming to the last page, we have Orchids, with which we started, a couple of Ferns, and finish off with a magnificent Trumpet flower belonging to the Bignoniads. This being the case in the first number, we must leave our readers to judge what the work will be like when completed, or rather finished.

* Re-issue of Paxton's "Flower Garden." London: Cassell, Petter, & Galpin.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

September 6.—Sowing annuals in 3-in. pots for spring bedding; potting cuttings of Centaurea candidissima and Cauliflower plants for early work; removing plants of Coleus from cutting frame, and putting them where they can have more air; setting Strawberry plants out singly to ripen their crowns; putting pot Vines into an airy situation; shifting late-sown Primulas into 6-in. pots; planting latest sown Endive; also some Endive in Asparagus trenches; planting Violets in frames, the manure in which should not be too hot, or they will not succeed; removing all nets from trees where not wanted; placing boards over some Endive to blanch it, but this is not so good a plan as tying it; syringing Gardenias well with clear water for bug, afterwards with 5 oz. soft soap to a large potful of water; manuring land for August-sown Cabbages; fumigating Orchids for thrips.

Sept. 7.—Sowing the latest Radishes; potting bulbs in loam, manure, and sand, and potting up Pelargoniums from the flower garden; tying up Chrysanthemums and spring-sown tree Mignonette; getting frames on Violet beds; digging land ready for Lettuce; getting manure for a new Mushroom bed; giving a little guano

Flower of the Spiny Bear's-breech (Acanthus spinosus).

to Celery and sloping sides of trenches slightly to let in more light and air.

Sept. 8.—Potting Hollyhocks and putting them into a pit; also Roman Hyacinths (five to a pot) and Roman Narcissi (three to a 4½-in. pot); planting main plantation of Strawberries; gathering Cox's Orange Pippin Apples; all Onions nearly harvested; earthing up latest planted Cauliflowers. Plants ready for house decoration:—Asters, Mignonette, Sedums, scented-leaved and double-flowered Pelargoniums, Fuchsias, Maize, Zinnias, Scutellarias, scented Verbenas, Heliotropes, Amarantus, Petunias, Balsams, Vallota purpurea, Musk, Rhodanthe, Coleus, Lilium lancifolium, L. auratum, Justicia carnea, Nerine, Agapanthus, Hydrangea, Tuberose, Plumbago, and Primula.

Sept. 9.—Sowing Mustard and Cress, some under cover, and some in boxes in heat; re-sowing Spinach where first sowing had failed; potting off Mangles' variegated and Mrs. Pollock Pelargoniums, putting the latter under glass; potting and plunging bulbs in sand; put in cuttings of Cerastium in a frame; planting some more July-sown Cabbage and some more Endive on Onion ground; taking off runners from Strawberry plants in pots; tying up more Endive for autumn supply; gathering Williams' Bon Chrétien and some Louise Bonne Pears; pruning Laurels again, being particular not to injure the foliage, also Cotoneasters on walls; exposing Tomatoes to the sun; Calceolarias, Pelargoniums, Phloxes, and Fuchsias, that were put at the back of a north wall early in June and stopped, and which were about the first week in August put on the south side, and when the flowers began to expand removed under glass, are now in small pots, and in good condition for stands.

Sept. 10.—Potting all outdoor struck variegated Pelargoniums; shifting Primulas from cold frame behind wall to pits in the sun; pricking out Cauliflower and green and red Cabbage; sponging Camellias; syringing young Vines with strong soap-water for thrips; gathering autumn Bergamot Pears and Keswick Codlin Apples; lifting first field Potatoes; putting hand-glasses ready in which to prick out Cauliflowers; cutting from Cabbage quarter any useless heads, in order to induce the stumps to form sprouts; pinching off all runners from Strawberry plants in pots, and clearing old Strawberry plantation.

Sept. 11.—Potting Tom Thumb and other green-leaved bedding Pelargoniums; moving Heliotropes in pots under cover; planting a large piece of August-sown Bath Cos Lettuce, also Cabbage Lettuce, Stanstead Park, Victoria, and Wheeler's Tom Thumb for winter and spring; staking and tying October Mignonette; going over and nailing wall trees; gathering Peaches, Nectarines, Cherries, and Currants, also Apples, Fondante d'Automne and Thompson's Pears, and Capsicums; putting Basil and Marjoram in a box in a dry place; cleaning Asparagus beds, seed beds, and Celery ridges; getting all frames and cases painted, and putting sulphur on pipes to keep down mildew on young Vines.

Glasshouses.

Primulas.—Late-sown Primulas required for flowering in spring should now be shifted into 6-in. pots, which, with the aid of manure water, will be found large enough for fast-growing, soft-wooded plants. Primulas like a compost consisting of good fresh loam, with one-sixth leaf-mould and a little sand. Press the soil firmly in the pots, letting it come well up to the base of the under leaves, so as to keep the plants secure in their places without rocking about, as they do when not potted low enough. Let both these and the earlier sown plants intended to flower through the last months of the year and early portion of the next be for some weeks yet in cold frames exposed to plenty of air, elevated close up to the glass, with the lights off in fine weather, particularly at night, as exposure to the dew is of considerable service to them. A piece of very thin, open netting stretched over the frames during the daytime when the sun is on them will be much better than exposing them to its full influence.

Cinerarias.—Attend well to those which are rapidly filling the pots with roots, as any deficiency in the way of water will so far injure them as to cause the loss of their lower leaves, and when that happens, however well flowered they may be, they lose half their beauty. Let the plants be looked over every ten days in order to see that aphides do not get a lodgment on them, or a like loss of leaf will be the result. If the plants be fumigated to destroy aphides it should be done lightly, or the foliage will be liable to get injured. The safest course is to watch closely, and immediately a plant is affected with either aphides or thrips to dip it in Tobacco water, a supply of which ready for use should always be at hand in every garden, large or small, especially during spring and summer, when these insects come to life so quickly.

Double Petunias.—Cuttings of these should now be put in for flowering next spring and summer, after which the old plants, when done blooming, may be thrown away, as young ones are in all respects better, and occupy less room.

Nierembergias.—These are very suitable to edge vases for summer decoration, where their drooping habit and profusion of flowers are seen to advantage. They are particularly adapted for use in window boxes or for room plants. Cuttings should at once be got in, selecting the softest shoots that have not a disposition to bloom. Put in the points of these 1 in. apart in 5-in. pots in sandy peat surfaced with ½ in. of sand; water them immediately and cover with a bell-glass, putting them in a warm house or frame. When they are struck they should be placed singly in small pots for the winter and kept near the glass. If they can be accommodated with a temperature of 45° in the night it will keep them growing.

Ferns.—In places where Ferns are grown, if the plants stand on any loose material that will hold moisture, such as ashes or sand and fine gravel mixed, kinds like Pteris serrulata, and the varieties of Adiantum, such as A. cuneatum, formusum, and pubescens, will drop their spores and vegetate in quantity without the

trouble of a special preparation in sowing them. The young plants that thus come up in spring will now be large enough for putting singly in small pots; for these do not use them too large, but in all cases let them be proportionate in size to the plants. Peat is the most suitable soil in which to grow them when it can be had good, but where not easily procurable, these and other Ferns will grow in ordinary loam, always taking the precaution of keeping it porous by a liberal admixture of crocks broken to the size of Horse Beans; or coal cinders will do equally well broken small, to which some sand has been added; the proportion of this latter, for these as for all other plants, cannot be exactly determined, being dependent upon the quantity of sand the soil naturally contains. Ferns, unlike many plants, should, as soon as potted, be immediately watered, for if ever the soil be allowed to get so dry after potting, as is needful for subjects that do not require so much water, they will flag, and whenever this occurs to a Fern, especially when its roots have been disturbed, as in the case of potting, it receives serious injury, and generally loses many of the fronds. The cultivation of Ferns is often associated with the idea of a dark, heavily-shaded situation. This produces a disposition of the fronds to damp off in winter, especially if the growth has been made in too close and warm an atmosphere. Ferns so treated generally make very large, deep green fronds, but not enduring; the varieties above named, which are so useful for general purposes, can scarcely be grown with too much light, provided they are shaded slightly from the direct rays of the sun when it is powerful. Older plants of Ferns, such as the above grown for cutting, should be kept in comparatively small pots; by this means any disposition to luxuriant growth is checked, and they will stand in water for several days.

Flower Garden.

Beds and Borders.—The mixed or herbaceous border should now have careful attention, as Phloxes, Pentstemons, and many other late autumnal flowers will now be in full beauty, and should not be in any degree marred or disfigured by being associated with the decaying flowers and foliage of other occupants of the border, nor should such plants be by any means cut down prematurely or in an unripened condition; but, at the same time, all dead and decaying matter may be removed with advantage to them as well as to the general appearance of the garden. As regards annual plants, they should be at once removed as soon as their beauty is over, unless in cases were seed may be required, and this should be carefully picked as it becomes ripe. A border of herbaceous and Alpine plants and bulbs, whether situated upon the margins or belts of flowering and evergreen shrubs or otherwise, should be so arranged as to have the flowers peculiar to the different seasons so distributed throughout the entire length and breadth of the border that no part of it will, at any season of the year, be entirely destitute of flowering plants; and care should also be taken to properly graduate the various species as regards their height, so that dwarf-growing plants may not find themselves partially hid or overshadowed by taller-growing sorts. Beds or clumps of double-flowered Zinnias are now in fine condition, and are most valuable as autumnal-flowering plants, and possess the power of resisting drought to a very considerable extent, especially if a deep, rich, and well-manured soil has been selected for them, and such encouragement they well deserve. Go carefully over the beds now and select a few of the very finest and most distinct blooms as seed-bearers, and mark them by securing to them pieces of coloured worsted or other material, and pick them as soon as they are ripe. By this means the strain will be continually improved, while the reverse will be the case if the seeds are gathered indiscriminately. Let Chrysanthemums, German and other Asters, as well as all other late-flowering plants, be carefully staked to prevent them being blown down or injured by high winds. Order, or get in readiness, the various bulbs which will soon be required for furnishing the flower beds for spring. The cuttings of such plants as the Verbena, Petunia, Coleus, and Alternanthera, which may have been struck in close frames or pits, will now, in most instances, be well rooted, and the store pots or pans containing them should be placed on cinder ashes in the open air, fully exposed to the sun for some time, or as long as it can be done with safety; this will have the effect of rendering them robust and hardy, and it is of the greatest importance to have them in this condition before the approach of winter.

Window Plants.—Remove plants that have done blooming, and always endeavour to have good healthy foliage if flowers are scarce. The Ivy-leaved Pelargoniums are the best of all window plants; display them to advantage, and pick off seeds and decaying leaves from Tropæolums. Balsams and Asters are now very pretty in windows, as are also some plants of Tagetes and African Marigolds. Give plenty of water to plants of Creeping Jenny, and permit the shoots of the Virginian Creeper to droop in graceful festoons. Introduce a few Cockscombs, yellow Calceolarias, Grasses, and any other miscellaneous plants obtainable. Indeed, a very pretty ornamentation in the window is the Japanese Maize grown in pots. Mesembryanthemums, too, are very useful for a dry position, and Gazania splendens for a sunny one. The various small-leaved Ivies, too, should not be forgotten; they are useful for suspended baskets, screens, or for spreading over balconies, and they grow and thrive under even adverse circumstances. Ferns and Selaginellas are also, as everybody knows, excellent for windows, especially those facing the north or east; and for windows facing the brightest sunshine, Acacia lophantha, and other kinds of Acacia, some sorts of Asparagus, Convolvulus mauritanicus, Grasses, and other plants of that sort are suitable.

Fruit.

Vines.—Examine the inside borders of late Vineries, and see that the soil is not too dry before the Grapes become nearly ripe. Where such is the case, lose no time in giving sufficient water to mature the crop, and also to keep the soil moist enough to prevent the fruit from shrivelling during winter. Every favourable opportunity must be taken advantage of to push on very late Grapes this month, for the decrease in the amount of sun-heat, which will be felt in subsequent ones, will be unfavourable to their development. Late Grapes are better flavoured when thoroughly ripe by the end of September than later, and they are not so liable to damp throughout the winter when in this state as when only partially ripe. Gros Colman is in many instances a bad kind to colour, but it often eats well when tinted with green. No anxiety need be felt about the colouring of the Black Alicante; it will do so under all circumstances. The surface of the border under Grapes ripe for autumn use should now be kept very dry, to prevent damping amongst the fruit; and do not rake or stir the loose surface-soil, or a great deal of dust will rise to rest on and disfigure the berries. Keep the ventilators of all Vineries in which the fruit is all cut wide open night and day, so that the fruit may become ripe as soon as possible.

Peaches and Nectarines.—If it is found difficult to get the wood of these fully ripened in orchard houses owing to the growth being more profuse and luxuriant than usual, the only way of aiding maturity will be as soon as the fruit has all been gathered to cut out all useless spray and shoots, tying out the remainder thinly, and then to apply artificial warmth, accompanied by a moderate amount of ventilation, till the wood begins to get brown and hard; the trees may then be gradually inured to bear full exposure. Though the fruit is gathered, inside borders must still receive good supplies of water, and syringing must be resumed to keep down insects, and so preserve the foliage in a healthy condition till the fruit-buds are well developed.

Strawberries.—Plants in pots should now have abundant space, in order that air may play about the foliage. The pots should be occasionally lifted, to prevent any roots entering the ashes or gravel on which they are placed. Keep all runners persistently pinched off, and pull out weeds as soon as perceived, for if left to get large there must necessarily, on their removal, be a certain amount of mutilation of surface rootlets. If after heavy rains any are waterlogged, turn out the plants and rectify the drainage, for there can be no healthy root action whilst the plants continue in such a condition.

Vegetables.

In a well-managed kitchen garden what is termed the busy season extends throughout the year, but if there ever were a slack time it would be during the present month, when, for the most part, all winter crops have been sown or planted, and others, such as Onions, Potatoes, &c., harvested. Any spare time, however, may be devoted to the destruction of weeds. All Potatoes of whatever kind ought now to be lifted. Winter Greens and Broccoli planted between the rows of Potatoes will now require earthing up. Regarding the utility of this practice, there can be no doubt that it is highly beneficial, both as a support against wind and as favouring the production of a large amount of stem rootlets, which are of the greatest service to the plant. Continue to plant all ground as it becomes vacant either with Coleworts, Cabbages, or sprouting Broccoli. If not yet sown in sufficient quantity seeds of the following vegetables should be got in at once, viz.: Chirk Castle Blackstone Turnips, Bath Cos and Hardy Hammersmith Lettuces, Early French Horn Carrots, Turnip-rooted Radishes, and Winter Spinach. Thin out former sowings as early as the seedlings can be handled, and keep the surface soil about them open by hoeing whenever the ground is sufficiently dry to admit of that being done. August-sown Cauliflower plants ought not to be left in the seed bed to become drawn or weakly; a good sturdy plant that will winter well can only be ensured by pricking out early. If the ground be ready for them, those that are intended for wintering under the protection of handlights may be planted in that position at once, and the lights can be put over them any time before there is danger of injury from frost. Box edgings should be clipped, also hedges, and all decaying vegetable refuse should be removed to the manure heap.

Unless where a deficiency of winter vegetables has been put in, and there are good strong plants at hand of Kale or Coleworts, it is not advisable to plant more of the ground that becomes vacant after this, as the time intervening before the growing season is over is not sufficient to admit of these late-planted crops attaining a useful size, and they seriously interfere with the preparation of the ground for another year without making any adequate return. Let all haulm of Peas, French and Broad Beans, or Lettuces that have run to seed, or anything of a similar description, as soon as they have ceased to bear or to be of further use on the ground, be at once removed. It is a mistake to allow anything of this kind to remain, for so long as any growth continues, it is so much extracted from the soil to no purpose. They should, therefore, be conveyed to the refuse heap as soon as possible. Let all ground be well hoed as often as weeds make their appearance. These will not cease to spring for some time yet, growing, as they do, with a lower temperature than most cultivated crops. Where salads are in demand, especially in the spring, it is well now to sow a little Corn Salad and American Cress.

Warm Exposures for Flowers, Fruits, and Vegetables.—From observations made in different parts of the country, I have come to the conclusion that the south, south-west, and west are the only exposures in a garden worth utilising for the culture of early crops of flowers, fruits, or vegetables. A south-east wall gets the full force of the sun when it shines from early morning till about 11 a.m., but it never experiences the intensity of the sun's rays like a west wall, which is always much the warmer of the two; and, besides, the crops on an east border are more liable to suffer from frost, because the sun shines upon the frozen plants before they are thawed; this they are sure to be on a west border before the sun reaches them. For producing early crops of such fruits as Apricots, Peaches, and Cherries—the latter of which do uncommonly well on a warm wall—there is hardly any position so favourable as the angle of a dwelling house facing the south-west. The heat radiated from both walls after twelve o'clock on a sunny day is often more than tropical, and greater than the temperature of an ordinary south wall. We have seen the thermometer record about 140° in the angle of a house wall in the north. When early Roses are wanted, no better situation can be had for them. A good climber,

like Gloire de Dijon, Maréchal Niel, or, indeed, any of the dwarf kinds that naturally flower early, produce flowers three weeks or a month earlier in such corners than elsewhere. It is the shelter from cold winds more than the protection from frosts which hurries vegetation.—J. S.

ROSES.

Rose Hedges.—We never heard any one remark that they had too many Roses; indeed, in nine gardens out of ten there are no more than are sufficient for room vases and other indoor decorations. If Roses be, however, wanted in profusion, either for cutting, for pot-pourri, or for other purposes, plant Rose hedges on the fringes of the lawn or alongside woodland walks and drives; or if Briers already exist, bud them with any of the vigorous, free-blooming varieties that may now be found in cultivation. Bud, in short, all the Briers that exist within half a mile of the house, and then after a time there will be Roses enough for everybody. It should never be forgotten that the soil on which Briers will grow will produce the most lovely Roses, and that wherever there is a fence of Hawthorns, Crabs, or Sloes, there the finest Pears, Apples, and Plums would grow equally well. A hedge of Sweetbriers is a luxury, even in the most princely garden; there is one at Moor Park, and most fragrant it is after every summer shower. Among the Roses best suited for hedges, none are better than Gloire de Dijon, Maréchal Niel, Noisettes, Banksian, Ayrshire, Boursault Amadis (itself one of the best of stocks on which to graft or bud delicate Teas and Noisettes), climbing Devoniensis, Lamarque, and the common Sweetbrier. If variety of colour or fragrance be desired, then interplant with Clematis and golden or scarlet-flowered Honeysuckles and the white Jessamine. A Rose hedge once well planted requires very little attention afterwards; a little shortening back of the too luxuriant shoots, and a mulching of rotten manure and leaves every winter will be sufficient, an outlay which will be amply repaid in the shape of plenty of Roses.—B.

Striking Rose Cuttings.—If "Mark" will leave the striking of his Rose cuttings until the end of September, when the sap is running down, and use ripe shoots of the year, and allow the cuttings which root to stand undisturbed until the following October, he will most likely get over his difficulty, and have a nice lot of own root Roses.—J. D.

Climbing Roses.—I am sorry I do not know the name of the cluster Rose which has done so well this year. It is rather uncommon, I think; I only know one other garden where it grows in my neighbourhood (Redhill, sandy soil). I shall be happy to send any one flowers when it blooms next year. Many gardeners would know its name, but I have not met with one who does.—MARK.

Bone Dust as Manure.—With reference to a remark in GARDENING August 7 respecting bone dust as a manure, I believe it to be one of the most valuable in existence when it can be obtained pure, but the difficulty of procuring it unadulterated often prevents its use. The fact is many of the men who collect this (before selling it to the dealers) mix with it such a quantity of foreign matter, as lime rubbish, silver sand, sawdust, &c., that after it has again gone through another mixing by the dealers it is comparatively worthless, having but very little of the genuine article in it. I have made quantities of this for many years (being a bone brush manufacturer), and the collectors have often paid me a higher price for it when pure than the dealers have charged after its having passed through the hands of both themselves and the collecters. Moreover, the exhorbitant price often charged prevents many from purchasing the article. The price in its pure state (or as pure as it can be swept up from the floor of the workshop) should not exceed 12s. per cwt.; but care must be observed in its use, as only a small quantity mixed with the earth, or thrown over the surface, will be found sufficient; but those wishing to use it in Vine borders will find the bone pieces more useful, as they last many years in the ground. REUBEN OAKELY.

House and Window Gardening.

Harrison's Musk as a Window Plant.—Young plants of this in 3-in. pots, placed in a window early in spring, will continue flowering continually, if well supplied with water, until midsummer. They should then be potted into 6-in. pots, and the shoots should be carefully pegged down over the new soil; they will then go on growing and flowering until late in the autumn. They require plenty of moisture at the root at all times. Another good way is to put in a pot or two of cuttings about midsummer from the old plants. Five cuttings in a 4-in. pot placed in a shady frame or in a window under a bell-glass will soon strike and form bushy plants. In turn the tops from these may be removed and put in for succession.

Gardening on Window-sills.—Some time ago I saw the following simple, but very effective and inexpensive mode of making a window-sill continually bright and pretty: Some wire netting was fastened to each side and filled with common Moss; in this were sunk to the brim pots containing flowers of any desired sort or colour. The Moss prevented the plants from getting too dry, and with a little water they were kept in good growing condition. I think that those beautiful Forget-me-nots, named by "T. F." in your issue of August 7, could be grown to perfection by this simple method.—T. FRIP.

Wasps' Nests.—A simple and effectual way of destroying these is to pour into the hole after dark about a pint or a quart of coal tar, then stuff in a brickbat and pour more tar on to it. Another remedy is to pour into the hole about half a pint of paraffin oil. If burnt out with brimstone, melt the brimstone first in a pipkin; then pour it on to a sheet of paper, which roll into a scroll about the thickness of your wrist; light it and place it in the hole; then blow gently into the hole with a pair of bellows, after dark of course; afterwards little annoyance will be experienced from wasps.—H. Z. BREWSTER, *Wrentham Lodge, Exeter.*

The Thrush a Snail Destroyer.—The thrush is no favourite of cultivators, owing to its being fond of bush fruit. Judging from what I have observed of the doings of this bird, however, I am of opinion that the harm which it inflicts upon us is more than counterbalanced by the amount of snails and slugs which it destroys. I do not believe that there is any wild bird so voracious in this respect as the thrush. This season a family of these birds found their way into a small plantation of Raspberries, and I noticed at times a sharp knocking like that of hitting one stone upon another. This I eventually found to arise from one of the birds making use of a large stone upon which to break the shells, and a hetacomb of these lying around plainly indicated the havoc which had been made amongst them. Previous to this discovery, I had observed an unusual number of empty shells scattered about. The parent birds had, doubtless, fed their young upon their contents. I am convinced that were it possible to tame and keep a pair of thrushes in a garden, we should be but little troubled with snails and slugs. To many who may have been annoyed by the depredations of this bird, it may be some consolation to know that during the greater part of the year it lives mainly upon that which is one of the greatest scourges of both the professional and amateur cultivator.—J. C.

Heckfield Place Gardens.—In accordance with now an established rule, Viscount Eversley will throughout next week, dating from September 6, throw open his beautiful gardens and grounds free to the public. In doing this the noble lord displays a degree of unselfishness not too common, alas! amongst the rich, too many of whom prefer to keep their fine gardens and mansions to themselves, and rigidly exclude all unprivileged outsiders. The gardens at Heckfield are very beautiful, and the grounds superb. In all departments the work is well done, and many a useful lesson in gardening may be learned by a visit. The place is situated in North Hants, near Strathfieldsaye, the residence of the Duke of Wellington, and also near to the historic mansion of Sir W. Cope. It is five miles from Winchfield Station, on the South-Western Railway, and the same distance from the Mortimer Station of the Great Western line. It is also about nine miles from the towns of Reading, Wokingham, and Basingstoke.

Saving Flower Seeds.—When nearly ripe the pods of Stocks and other plants generally open a little. Then gather, and hang them up in a dry place over a sheet of paper, on which they will fall. Any that do not can be rubbed out by hand.—B.

To Keep Flower-pots Clean.—Dirty flower-pots should be well scrubbed with hot water and strong soda. I never allow a pot to be put away or used again till clean and red; it is a slovenly habit, and very bad for plants to allow the green to remain on.—B.

Heating Greenhouses.—In answer to many inquiries on this subject, we think we may justly draw the attention of our readers to a new terra-cotta stove and boiler combined, heated by paraffin or gas, now being made by Mr. Broadbridge. We have seen it in action, and as far as we can judge at present it is just the thing that is required for small greenhouses. It is constructed so as to give off a moist heat, whilst all the fumes from the paraffin are carried out of the house through a tube. During summer, when not in use, the stove can be stored away if desirable. When a moist heat is not requisite, which it is not always in winter, the boiler can be left empty with safety, but cold water must not of course be poured into it while the lamp is burning.

GLASSHOUSES & FRAMES.

Abutilons in Greenhouses and Windows.—These beautiful flowering plants are amongst my chief favourites for greenhouse and room decoration, and well repay the care and attention of the grower. I cannot help wondering that these are so seldom included in our collections of indoor flowers, but I am sure those who once grow the Abutilon will rarely be satisfied without obtaining several of the numerous varieties of it. A. Boule de Neige is the one most commonly grown by amateurs as well as the market gardeners, and its pure white, bell-shaped flowers, produced in such profusion, are greatly sought after and much admired. A. roseflora is another very good variety; the blooms are a beautiful salmon colour veined with crimson. These two are especially valuable for winter blooming, the first particularly. We also have several variegated Abutilons, as the well-known tessellatum, with its pretty marbled leaves and curious crimson tassels tipped with yellow, which always proves a great addition when placed amongst other dark foliage plants. One thing every person will be glad to know, and that is, they are very easily propagated by taking the young shoots about 3 in. long, and covering them with a bell-glass in a warm greenhouse. In three or four weeks they should be well rooted without the aid of bottom-heat. All this class of plants produce their flowers in the same graceful drooping way, very like our old favourite the Fuchsia, and when one sees a large well-grown specimen Abutilon covered with crimson, yellow, or white bells, it is certainly an ornament to any conservatory.—W. A. G.

Grevillea robusta from Seed.—This is one of the most useful of green-leaved plants for decorative purposes, and it is now largely grown for market. Seed of it sown early in spring will, if properly attended to, produce fine, graceful-leaved plants, from 12 in. to 18 in. high by August. We lately saw a large houseful of similar-sized plants, the result of seed sown at the time named.—S.

Wintering Half-hardy Plants in Frames.—Although the system of heating houses and pits with hot water has greatly simplified the keeping of tender plants through the winter, and, to a great extent superseded cold frames and pits for that purpose, yet it frequently happens that small cultivators have no heated structure of any kind, and, therefore, necessarily fall back on the somewhat antiquated, though by no means to be despised, two or three-light frame, that, during summer, is usually devoted to Cucumbers, &c. I have seen a good many plants safely wintered as follows: As early

as cuttings are procurable, say in the end of July, commence propagating Pelargoniums. Get some boxes 4 in. deep, and of lengths most convenient for storing purposes, and fill them with tolerably fine, sandy soil; in this insert the cuttings, prepared in the usual manner, about 2 in. apart. These will root freely in a fully exposed position if moderately supplied with moisture, and they will be well established in the boxes before winter sets in. During August such tender, soft-wooded cuttings as those of Lobelia, Alyssum, Verbena, &c., may be readily propagated in store pots under hand-glasses or cloches set in a tolerably shaded position, giving a little air at night, picking off any decayed leaves, and giving water sufficient to keep them from flagging. The pots should be well drained; at least, they should be one-third full of potsheds, over which should be put a covering of rough soil, finishing with finely-sifted soil and clear, sharp sand. As soon as they commence to grow, which will be in about three weeks from the date of insertion, give more air, and after another week remove them to an open situation, but sheltered from rough winds. The growing points and all flower-buds must be kept pinched close, in order to induce a dwarf, sturdy habit. About the end of September, or early in October, set the frames on a good, hard foundation of well-trodden coal ashes that will keep worms down, and super-abundant moisture from rising. A sheltered position fully exposed to sun and air is best, as at all seasons, when there is not actual frost, plenty of ventilation should be given, as stagnant damp is more frequently fatal than frost. The latter, however, must be guarded against by means of dry litter put over the glass, and the sides may be securely protected by dry leaves packed firmly about 1½ ft. thick all round. If the boxes and pots be elevated on a hollow stage all the better, and only sufficient water to prevent flagging should be given until the days begin to lengthen. Then any which it may be desirable to increase may be removed to closer quarters to promote young growth for cuttings, as where means for propagating are at hand, spring-struck plants from those kept in store pots, such as Verbenas and Lobelias, are the best. Pelargoniums, however, are best struck in the autumn. Where space will allow, these should be potted off early in spring, and as soon as they have become well established under glass, they may be hardened off under some temporary protection. If intended to remain in the boxes until they are planted out, strong-growing varieties must be allowed more space.

Climber for Warm Greenhouse (Bougainvillea glabra).—Among climbers, the blooms of which adorn the roofs and walls of our plant houses, there is none more beautiful than this Bougainvillea, owing to the large size and profusion of its mauve or rather pink bracts. Bougainvilleas inhabit the warm, semi-tropical valleys lying along the upper tributaries of the Platte River, the banks of which are clothed with an infinite variety of tropical productions. Skirting the forest, the Bougainvillea may be seen growing rampant among the branches of some tree, which it festoons in a gay but artless manner, not without injury, however, to a sapling. This luxuriance, which lasts in greater or less abundance about nine months, is promoted by copious rains, clear sunshine, atmospheric influences, and decayed vegetation, but with winter comes a check; sometimes the leaves fall emtirely, but in ordinary seasons they are partially retained, and the dormant state quickly passes into one of active growth. These conditions indicate that we should grow the Bougainvillea in a brisk-growing temperature, on the one hand, followed by a decided rest on the other—treatment which experience verifies, judging from the behaviour of Bougainvillea glabra during a series of years. It is grown here in a 20-in. pot or tub, placed on a stone table 2 ft. above the pipes, at the warm end of an intermediate house, the thermometer often falling to 45° in midwinter. It is in autumn one mass of bloom. The entire plant covers an area of 100 sq. ft. With the departure of bright sunlight and the approach of winter, growth reaches a minimum. In January the ripened shoots are pruned to short spurs; after a few weeks more the roots are examined, some new soil supplied, and the stem tied up horizontally near the glass. During the resting period water is not entirely withheld, because I consider the "dry-as-dust" practice injurious to the roots; the atmosphere is also somewhat moist. In March the buds break with renewed energy, root action follows, the vigorous nature of the plant becomes apparent, a fact which appears to me to form the basis on which success or failure, as regards continuous flowering, mainly depends, for if the advancing shoots be not first thinned and afterwards pinched at every lateral, the annual result is an exuberance of immature growths with very little bloom. But let the shoots be kept evenly apart and trained carefully to the wires, as one would do with a Peach tree on the frame method, and the sun will not fail in perfecting the growth, in strengthening the whole plant, and indicating abundance of blossoms. Supplies of water and liquid manure, shading from the direct rays of the sun, frequent syringings, and clean glass are also indispensable to secure good results.—J. S., *Edinburgh.*

Variegated Adam's Needle.—This, the botanical name of which is Yucca filamentosa variegata, is one of the most handsome of fine-foliaged plants. It requires a cool greenhouse temperature and good sandy peat and turfy loam in which to grow. It is not an easy plant to cultivate, but it well rewards the attention it requires. The green-leaved form of the plant is perfectly hardy, and flowers freely when planted in well-drained soil.

Variegated Adam's Needle (Yucca filamentosa variegata).

SUBURBAN GARDENS.

I SHOULD much like to know how it has fared with the amateur gardeners this year, more particularly in the neighbourhood of London, in order that I may compare their accounts with my own experience of this rather disappointing season.

To begin with almost the finest March on record, with regard to sunny days, the spring flowers, such as Crocuses, Primulas, Auriculas, and their contemporaries, were very good. The Almonds were very late this season, mine not coming into blossom before April. By the way, how is it the Almond fruit is not more utilised with us in England? In the softer stage they make a very fair pickle, something like Walnut and quite tender. I have had them made into tarts, which were not bad precursors of Gooseberries. Later on, before the kernel gets too hard, they are much appreciated in Pau, and were selling there last year at 50 centimes the pound. My Almond trees were in blossom with the Pear, which is not of very usual occurrence. The Gooseberries and Currants did not promise very well; there has, moreover, been a great deal of sickly wood to cut out. The blossoming of Apples, Pears, Plums, and Cherries promised great results, but the promise has been terribly nipped. Strawberries were plentiful, but much damaged by wet, and possessed but an indifferent flavour; Raspberries plentiful, but likewise suffered from wet and have damped off. Of the scanty crop of Currants and Gooseberries the birds had the better half, and the branches are now a sad sight, the foliage being entirely eaten up by caterpillar. Apples and Pears, save in one or two instances, *nil.* Tho wood did not ripen well last sunless year; and the branches, which were covered with blossom in May, are stick dry and dead in August. Grapes, outdoor, none. Take it altogether, I think this is the worst year I have had during the twenty years I have inhabited my present neighbourhood, between Wandsworth and Wimbledon. My garden is not extensive, and my principal crops of vegetables are generally Windsor, French, and Scarlet Runner Beans, and the Butter or Mont d'Or Bean—a most delicate and delicious vegetable, not sufficiently appreciated; it should always be served apart from, not defiled by contact with, meat. My first crop of French Beans failed; the slugs and the small birds divided the spoil. The subsequent sowings will not prove quite successful. The Windsor did pretty well. The Mont d'Or promised well, but have run terribly to leaf; the pods are getting on, and, with a continuance of fine warm weather, we shall have a golden crop. Peas, what were left by the birds, turned out well, and I think we shall realise with Salsafy and Leeks. Celery is growing well. Potatoes I did not try this year. Salading I shall hardly try again; it barely pays, as you can buy it so cheap in the neighbourhood of London.

As regards flowers, my soil is not very good for Roses, even with loam added, and the severe cold of last winter destroyed three-parts of them. I have done pretty well with Geraniums—pink, red, and fancies in pots. I planted or potted out from the end of April, beginning on a warm border. Fuchsias are late; some stand the winter out of doors, covered with Cocoa fibre, and are as early as any of them. Heliotrope and Ageratum are late; double Petunias have been very rich, and also the large Delphinium. Of the modern annuals, such as Godetia, Œnothera, Saponaria, which masses so well, Silene, pink and white, the almost forgotten Venus Navelwort, and many others, now failing—that fault of annuals—have repaid me for my trouble, and I hope to have a fine display of Dianthus chinensis. If the canariensis seeds ripen, it will be next year what it was some ten years ago—a weed; while since then I have paid for the seed at the rate of a halfpenny a pip. For many years I did remarkably well with Asters, the French designate so well by the name of Reine Marguerite. For variety, richness of colour, and size, I have never seen finer. I used to buy about ten shillings' worth of seed, sending a little to an old friend, now no more, an enthusiastic gardener. I must confess my Asters cost me a lot of trouble, and were a source of anxiety while I was away to myself and others. Of last year I will say nothing anent these flowers; what I have this season don't look likely to be famous. I am inclined to think the seed has not been so good during the last two or three years. It is not worth while going into more detail. I will just add, it has been a wonderful year for small birds, including thrushes. Now, I like Mr. Turdus Musicus, to see a little of him, and hear him sing. He is quite welcome to take a tithe of my Cherries, with a few over; but when he reverses that order of things, and leaves me barely the tithe, to say nothing of the few over, which I take it are eaten by his cousin Merula, I don't like it. I see them at it now, while I am writing this, in a Cherry tree opposite, protected by an array of standards fluttering in the breeze. In my boy days the thrush (grieve) was quite a favourite *plat* at decent tables in France. Now, I used to have a weakness for a thrush pudding; and if, after a season's fattening on my fruits, a few of these favourite songsters would yield me their carcases for my food, I might think well of that form of reciprocity. As it is, it is all free trade for the thrush, and no protection for me. If I fired off a gun my neighbours, and I have nervous ones—for instance, the two old maids next door—would be alarmed. I might shoot the cat on one side, and frighten the children on the other, which, after all, would be a righteous retribution for

their outrageous disturbance of my dreams and waking thoughts.—W. A. R., in *Field*.

Staphylea colchica.—This is one of the most valuable of shrubs for early forcing that we possess, although it is as yet rather rare. We have seen it shown at South Kensington in early spring by Messrs. Veitch & Sons, of Chelsea, where it was greatly admired for its wealth of ivory-white blossoms. It is propagated by means of cuttings, and likes a warm, light, well-drained soil; and it might probably succeed well grafted on stocks of S. pinnata, the Bladder-nut of our shrubberies. Now is a good time to get plants for forcing into bloom in winter.

ANSWERS TO QUERIES.

2722.—**Rusty Water.**—I take leave to tell you that lead pipes may easily be rendered perfectly safe as water conduits and cisterns also, where water is not impregnated by gypsum or sulphate of lime, by coating them with sulphate of lead, which is insoluble in water pure or containing vegetable acid. This is done by filling the pipes (if laid) with a diluted solution of sulphuric acid in water, one part to ten of water by measure, retaining it in the pipes by plugs to give time for the acid to penetrate to the lead (through any vegetable deposit). New pipes ought to be first subjected to the action of a boiling solution of soda ash to take off any grease in the pipes. For cisterns, new or old, scouring with sand and a strong solution of Epsom salt and sulphate of magnesia, letting the scoured lead dry (white), and rescouring dark parts, first scraping off any dark scales or accumulation, the acid solution is quite the same, but might injuriously act on the hands or clothes of the unskilled operator. The best scouring instrument is a piece of Cocoa-nut husk. If sulphate of lime or any other sulphate but that of lead is present in the water, lead pipes or cisterns are harmless, because the insoluble sulphate of lead limes them from decomposition of the sulphate by the lead. But pure water or that containing vegetable acids in any combination will dissolve lead, which thus becomes a truly dangerous poison to all mammalian animals, not the less so that it may be slow and obscure in its progress to the external symptons of lead poisoning. Leaves falling into leaden water cisterns in London have, by generating acetic (?) acid, photographed themselves in the solid lead in the process of their natural decay by the acetic acid biting away the metal similarly to aqua-fortis in copper etching.—J. B.

2841.—**Houseleeks.**—I think there is no other sort but the one you have got, Sempervivum tectorum, or Common Houseleek, which will succeed well on walls. But in Sedums, commonly named Stonecrops, you may get a good variety, both in plants and colour of blooms, which will grow in such positions you mention. The following are the names of a few that I think will be suitable either in boxes or on the walls or roofs: Sedum album, flowers white; S. anglicum, flowers white or pinkish; S. acre, flowers bright yellow. These rarely exceed 4 in. high. S. reflexum, S. glaucum, and S. rupestre bear yellow flowers, and grow from 6 in. to 1 ft. high; S. telephium (flowers purple) and S. rhodiola (flowers yellow) grow up to 18 in. high. I cannot say where these may be bought; but they grow wild on rocks, mountains, walls, and gravelly places along the sea coast. I have seen some splendid specimens in Lincolnshire and Wales.—J. J. NEWTON.

2828.—**Hibiscus africanus.**—This pretty annual is a little difficult to manage. It is just on the borderland between hardy and half-hardy. In seasons such as we sometimes have when there is no spring to speak of, and cold weather at the end of March is followed by hot weather in April, it would no doubt prove a hardy annual; but in cold, wet seasons, when winter lingers in the lap of spring nearly up to Midsummer Day, the seed rots in the ground, and what does germinate, even in a dry soil, gets on very slowly, and barely justifies its occupation of the ground. I found the best way to manage it was to sow in 7-in. pots in a sunny greenhouse, thinning out the plants to one in each pot, and plant out with balls of earth entire as soon as the weather was warm enough.—J. D.

2842.—**Cleaning Garden Pots Equal to New.**—Hydrochloric acid will burn the hands and clothing; it is also poisonous; it dissolves rapidly both zinc and iron, of which metals galvanised iron is a combination; it has no action upon lead, so that an old leaden cistern would answer to hold it in; any earthenware vessel glazed inside would also suit. If a pan of clean water in which some washing soda is dissolved be kept close handy, the hands could be dipped in that when the soda and acid on the hands could combine to form common salt. A white linen overall could be worn over the dress, and washed in soda and water after using. The hydrochloric acid of commerce is impure, and should not be allowed to stand in a leaden vessel if that is used.—J. D.

2723.—**Plants for Greenhouse Walls.**—I do not think a list of names could be given, as it would occupy too much space. All kinds of stove and greenhouse Ferns and Mosses will grow on such a wall. All the fine-leaved Begonias, of which the B. Rex may be taken as a type, will be at home, as will also such ornamental-leaved stove plants as Fittonia argyroneura, Gymnostachyum Verschaffelti, Sonerila margaritacea, Tradescantia zebrina and T. vittata, and the variegated Grass (Panicum variegatum). Among flowering plants Gloxinias and Achimenes will succeed, as will also many other plants not now referred to.—E. H.

Ivory-flowered Bladder-nut (Staphylea colchica).

2782.—**Caterpillars in Cabbages.**—It is as well to persevere in handpicking the caterpillars from the Cabbages, as those destroyed now will lessen their numbers next year; but when they are so badly infested there is so little hope of making the present crop usable, that I should recommend the Cabbages to be cut and given to the pigs. If the Cabbage stalks are left, and the earth between them stirred up deeply with a hoe and some short manure spread among them, they will break out again, and the next crop, although smaller in size, will most likely be clean and free from insects.—E. H.

2783.—**Caterpillars on Gooseberry and Currant Bushes.**—There is, I think, some confusion about the caterpillars that attack the Gooseberry and their origin. My own impression is that the chief mischief is done by the larvæ of a sawfly named Nematus grossulariæ. The perfect insect or fly measures across the wings when extended about ⅝ in., and the body is about ⅜ in. long. They are gay-coloured insects, having yellow throat with black spots above and below, yellow body, legs of the same colour, and black feet. They have four wings. They hatch two and sometimes three broods in the summer, the last remaining in the chrysalis state all winter, descending and burrowing into the ground beneath the bush, entering the soil from 2 in. to 4 in., according to its firmness. The best time to commence the attack is in winter, by taking 3 in. or 4 in. of soil from under the bushes and replacing it with fresh; by this means many of the sleeping insects will be destroyed. Then again, a sharp look-out should be kept on the bushes in June, when the first insects appear. They lay their eggs on the underside of the leaf, in the hollow places alongside the midrib, and as they are then comparatively few in number may be easily destroyed.—E. H.

2631.—**To Preserve Cut Flowers.**—Put them in a glass and a piece of charcoal in the water, and set the glass on a plate and cover it over with a bell-glass, and put as much water on the plate as will exclude the air, and place it out of the sun. In the case of flowers with loose petals, such as Pelargoniums, &c., a drop of liquid gum dropped in the centre will make them stand much longer than they otherwise would do. To restore faded flowers cut a small piece off the end of the stalk, and dip the stalk in boiling water one minute.—HELP ONE ANOTHER.

2722.—**Impure Water.**—In a reply to this query in number for August 21, it is stated that 300 yards of lead piping would render water poisonous. As this might cause much unnecessary uneasiness to many people, will you allow me to correct this rather too sweeping statement. Rain-water or water containing no sulphates or carbonates in solution will

dissolve lead oxide and become poisonous, but very few spring or river waters are in this condition, sulphate of lime being present in most waters, or in its absence sulphate of magnesia. It has been abundantly proved that one grain of either of these salts in a gallon of water is sufficient to prevent the solution of lead oxide; therefore any water that causes soap to curtle (any hard water) is safe to keep in leaden cisterns, and to run through leaden pipes. The hardness of water before and after boiling is tested by Clarke's process with a standard solution of soap.—JOHN S. LINFORD, F. C. V.

2834.—**Garden Refuse.**—The best way to dispose of all garden refuse when there is not an animal to eat it is to dig a hole or trench 18 in. to 24 in. deep and bury it. Tread it in and chop it up with the spade, and, if possible, pour several buckets of house slops or liquid manure upon it, and replace the earth. In a few days it will settle down. The refuse should not be within 1 ft. of the surface, and when required to plant or sow over it, tread the earth to make it sufficiently solid. The fresher the refuse the better, and if this plan is continually practised, the soil will not only become deepened, but rich.

2578.—**Blight on Asters.**—I shared the same fate as John E. Cheese with my Asters, but have since very effectually cured them by thoroughly mixing 2 lb. of carbolic disinfecting powder (Sharratt's) in a bucketful of water, and allowing it to settle, and when clear syringing all the plants with the liquid. The leaves have now all uncurled and the flowers coming out well. I have also found it a perfect cure for all insects in the greenhouse, &c., and does not harm the plants.—F. A. S.

2783.—**Caterpillars on Gooseberry and Currant Bushes.**—I think the caterpillar mentioned by G. H. Mortimer turns into the magpie, Currant, or Gooseberry moth, one with black spots and blotches on a white ground; the upper wings have also some yellow markings. He had better kill all the moths he sees; it will at least lessen the number of eggs laid. They may be beaten out of bushes, or found resting on railings, and as they have a very weakly flight, may be easily caught. The yellow underwing caterpillars do no harm, as they feed on Dock and other low plants.—R. T. N.

2800.—**Ants in Houses.**—Get a tumbler, put in it two tea-spoonfuls of brown sugar or treacle and quarter tumbler of water; cover it with paper just tied round; make a hole in the middle of paper about the size of a shilling. Place the tumbler in the nest and you will soon find it thick with ants. I have tried this in my greenhouse and garden, and it has proved quite a success.—PH. N., *Jersey*.

2594 & 2597.—**Maggots in Carrots.**—As prevention is better than cure, I will give the method we practice about here, and we grow clean bright red Carrots free from worms, maggots, or scab, and of a large size. On every acre of land sow 12 or 14 cwt. of agricultural or house salt, and not less than 4 quarters (8 sacks), if more all the better, of soot. Mix the two with good earth or other soil (not ashes), and cart it on one month before sowing the Carrot seed, and either drag or harrow it in. My land is common sand, and this year's crop is on the same land as last year, and I have a grand crop of clean, large, bright Carrots. Where none of the above compost is used you can tell to an inch; no manure is required.—G. BROCKLESBY.

2626.—**Potatoes Diseased.**—Mr. Kane's answer to this question seems likely to me to do harm. I have a garden on wet clay, and have tried more than thirty different sorts of Potatoes. I have found burning the clay the best method. This year, after thirteen months' occupation, I have had a splendid crop of Potatoes. The only two touched with disease are Early and Late Rose, both a magnificent crop, especially Late Rose, which has produced about 20 tons to the acre. From one 9-yard row I got 56 lb. But the Roses and Snowflake are not to be depended on. Last year all grown in this garden were rotten. So far the best earlies are Veitch's Ashleaf, Sutton's Ashleaf, Rivers' Ashleaf, Alma Kidney, Golden Kidney, Myatt's Prolific Ashleaf. Paterson's Victoria were also all bad last year, and a great many Scotch Champion which did not eat well. Magnum Bonum, though continually in the water, produced four bushels of sound Potatoes from a bushel set, none bad, and they were all sound for replanting. The only bad Potatoes this year had accidentally been manured with road scrapings. Snowflake would have gone, but I got it up at once, though it was not ripe. Mona's Pride, Fenn's Early White, and Fenn's Bountiful were all good, but being smothered in Brussels Sprouts, did not crop so heavily. Excelsior I can't get at yet, because a neighbouring Magnum Bonum has extended over its protecting haulms. Finally, your correspondent had, in my opinion, better plant Snowflake, the two Roses very sparingly, not too much Champion or Victoria, and place his main dependence on Magnum Bonum for the late; Veitch's Ashleaf, Myatt's Ashleaf, Alma Kidney, and Golden Kidney for the early crop. I have used Amies' Manure for all the Potatoes, and I have not yet heard of any crop, even on favourable soil, which is nearly as good or heavy as mine on wet clay.—POOR CURATE, *Worcester*.

2885.—**Heliotropes and Verbenas.**—Both Heliotropes and Verbenas may be propagated now by means of cuttings, and some may be put in up to the end of September; later than that heat would be needed to induce them to strike; but unless there is heat at command all the winter it is not well to strike cuttings in heat in the autumn. If a few good stock pots of cuttings can be got to stand through the winter plenty of cuttings may be taken from them in the spring. The cuttings now should be made from stout growth that is not flowering, and the soil used should be ordinary pot-soil, having on the surface, one inch in depth, an admixture of one-half sharp, clean sand. When rooted the pots will keep well on a shelf in the greenhouse.

2833.—**Preserving Vegetable Marrows.**—Marrows for preserving may be of any kind, the larger perhaps the better, and should be quite three parts grown, the rind getting set, but not hard. In this stage the fruits are less watery and the flesh more solid. The proportion of fruit to sugar is as 6 lb. of the one to 4 lb. of the other. The Marrows should be peeled and cut into strips, the seed vessels being cleanly removed. The strips are then cut into small squares and put into the stew-pan, the sugar being at once added, as this hardens the pieces and prevents their boiling to a pulp, which is the result when the fruit is boiled half-an-hour before the sugar is added, but that is the plan to follow when jam is needed. About ¾ oz. of ground Ginger is added with the juice of two Lemons and the peel sliced up small. This is put in in the process of boiling. Two hours will suffice for that. It is not safe to trust Marrows to be hung by the stems, but they should be slung up in any dry, safe place.—A. D.

2799.—**Keeping Rain Water Pure.**—If "C. G." will take a trip to this village, Knockholt, near Sevenoaks, he can see "the best means of keeping rain water pure" carried out in the most simple, cheap, and practical manner. As, however, it may be inconvenient for him to pay a visit to this place, I will describe the mode adopted. Tanks of brickwork are built underground capable of holding say from five to ten thousand gallons, or more if required. These tanks are filled with the rain water falling from the tops of houses or other buildings through the ordinary gutters and pipes. A pump is connected with the tank either outside or inside the dwelling-house, and the water is raised in the same manner as raising it from a spring well. There are four tanks in the village for the gratuitous use of the villagers, and every private house has its tank. The water in the tanks being underground is entirely protected from the atmosphere, and is always in the greatest state of purity. Water kept in casks, as "C. G." proposes, very soon becomes putrid, has a bad smell, is totally unfit for drinking, and most disagreeable for any purpose. These brick tanks can be constructed by any well sinker or bricklayer, and are very cheap. It is necessary, of course, that they should be made waterproof by cement, and closed at the dome-shaped top with a close-fitting stone. Knockholt is about 700 ft. above the sea level, therefore the getting of spring water is quite out of the question. The great drawback to this beautiful part of Kent was, till within the last ten years, the scarcity of water, but since the system I have described of utilising rain water was adapted, there is no village of a high elevation in Kent, perhaps in England, that is so abundantly supplied with water, and that of the purest quality. I consume a great deal of water in my garden, more than I did when I lived in the suburbs of London. At that time it cost me at least £4 per annum. There are no water rates, and any person now building is compelled as a condition of granting a lease to construct tanks for the houses. The subject of utilising rain water in the country is a highly important one.—S. L. C.

—— "C. G." had better get one of Lipscombe's filters. Dr. Russell says of them, "Rain-water by Mr. Lipscombe's new process is rendered bright and sparkling as the finest spring water. Alum is said to purify water.—R. T. N.

2892.—**Maréchal Niel Rose not Blooming.**—As your Maréchal Niel Rose has not bloomed yet, although five years old, the inference is, that you have not the Rose at all, but only the stock, perhaps, on which it was worked. In the situation you name it is evident that the plant, doing well as you say, ought to have flowered abundantly. The true Maréchal does not like to be pruned only so far that weak shoots may be taken out now and then, but the strong robust shoots should be laid in to the utmost length, as these ought to produce flowering shoots from every bud the next spring. Perhaps, to make certain whether you have the true Rose or not, it would be well to invite an inspection of the plant by some one who may know, as the fact that it does not flower leads to the conclusion that it is not correct.—A. D.

2898.—**Storing Potatoes.**—An attic would make an excellent place in which to store Potatoes, because it would be cool, and you ought to be able to exclude frost in the winter if you would cover up well with sacks or any impervious material and loose straw. The best plan would be to get either some stout boxes or flour barrels and store the Potatoes in them, as they are then much less exposed to the cold air. One barrel or boxful may be kept in the cupboard for present use as needed. A shed in the garden is not a safe place either from frost or from vermin, but the Potatoes would no doubt be safe enough from frost there until the end of November. Altogether, we prefer the attic for the bulk when stored in tubs or boxes as advised.—A. D.

2827.—**Saving Flower Seeds.**—There are so many kinds of flower seeds, and there are so many diverse methods of dealing with them, that it would be impossible to describe in detail in a short paragraph the entire process of dealing with all. The simple thing to do in relation to common plants is to note when the seed-pods show ripeness, and then gather and expose to the sun until fit to clean out. Brown-paper bags, with the name of the flower seed saved written upon each are very useful with all seeds. It is essential that all should be thoroughly ripened before being put away in paper packets for the winter. Double Stocks do not seed—only single ones. Pinch out the points of the flower-spikes, and leave only a few of the best pods to ripen. The seed then is finer and more likely to produce double flowers.

2823.—**Caterpillars on Geraniums.**—There is absolutely no better method of getting rid of the caterpillars upon Geraniums than by handpicking, and it must be persistently followed up. If the branches of the plants can be well shaken, many may fall to the ground and then be picked up. As the skins of the insects are transparent, and the food they eat is green, their bodies are so much the colour of the leaves, that it is difficult to find them on the plants.

2831.—**Sowing Anemone Seed.**—The months of April and May is the best time to sow seed of Anemones in the open ground. The soil should be well prepared, deeply dug, and manured, and the surface well fined. Draw shallow drills 1 in. in depth and 10 in. apart. Mix the seed first with any fine dry material, that it may be well separated, then sow thinly in the drills, and cover with fine sandy soil. If sown under glass this may be done earlier in the year or even in the autumn, but the young seedlings should be pricked out thinly ere they become entangled with one another.—A. D.

2757.—**Cactus not Flowering.**—Water with boiling water once a week close to the edge of the flower-pot. I have flowers every summer. I had two plants full of beautiful blossoms this season. I water the same when in bloom. Mine are scarlet. Do not be afraid to try it.—LIZZY THOMPSON.

2789.—**Sewage in Gardens.**—Apply a liberal quantity to Cabbages and Broccoli, and upon any waste piece of ground, and if any remaining, dig a hole 2 ft. deep and empty the cesspool into it, and replace the earth.

2799.—**To Keep Rain Water Pure.**—The only way to have good rain water is to run it into a tank underground made of brick, or stone, or cement, to be pumped up and passed through a filter for use—the filter to be kept in a cool place.

2720.—**Thistles in Meadows.**—Pull them up by the roots early in spring or summer when the ground is soft, or keep them cut down continually with a large hoe, scythe, or hook. Gloves required for pulling.

2826.—**Nesida Rose.**—Perhaps a Noisette Rose is meant, sometimes called, Rosa Noisetteia. There are a good many varieties, varying in colour, habit, and hardiness.—J. D.

2842.—**Cleansing Garden Pots.**—Hydrochloric acid will dissolve the zinc off a galvanised pan and spoil it. It will not hurt a stoneware, china, or glass vessel. If there are no cuts on the hands it will not hurt them if a little diluted. It is poisonous.—W. L.

2785.—**Lily of the Nile not Flowering.**—Arums will not flower if kept always growing. About May I let mine dry off in their pots out-of-doors till the foliage is quite withered. Now they have just been repotted, and every bit of old mould shaken out of their roots and replaced with new. I find this an excellent plan, as they flower abundantly.—B.

2745.—**Moss on Gravel.**—Sprinkle it with fine salt in dry weather.

Slugs and Snails.—There is no better way of destroying them than the constant use of air-slaked lime dusted over the ground, and also over the plants which may be suffering from them.

Although the following questions are answered by the Editor, he will be obliged to any of our readers who may think well to answer them according to their experience.

2924.—**Barren Strawberry Runners.**—In the article on Strawberry cultivation I see it is recommended to take off all barren crowns. Now, may I ask the very important question, When? I went and looked at some plants, and I could not tell which crowns were barren. Of course, in spring, when the plants show signs of blossoming, it cannot be done.—OLD INDIAN. [An experienced eye will tell with tolerable certainty which runners will bear fruit and which will not. The fruitful ones show a plump crown, whilst barren ones have no crown at all, so to speak.]

2925.—**Brussels Sprouts.**—What is the earliest time that Brussels Sprouts can be picked? and when ought they to be sown and planted?—R. H., *Norwood*. [By sowing thinly in September and leaving the plants in the seed beds till February or March, and then planting in good land, Sprouts may be had in October. Sow again in February, March, and April for succession, planting out when large enough.]

2926.—**Fig Trees.**—I have two large Fig trees which are now putting forth a quantity of young fruit which never comes to perfection. What is the cause of this? and what should be the treatment?—W. E. V. [Want of warmth is the cause. Cover the trees up in winter with mats or straw, and you may get some fruits next summer.]

2927.—**Planting Rhubarb.**—I sowed some Rhubarb seed this summer, and the plants are now from 3 in. to 5 in. long. Will you inform me when is the proper time to plant it in the field? and the best ground? as I have some low and moist, and some dry. As it will not be fit to pull next year, can I plant anything that would make a crop between the rows? I propose planting the seedlings 3 ft. apart each way.—F. A. [It would be best to leave the planting till spring, as the seedlings are but small. Plant in the moist land, and well manure it previously. You may grow Spinach, Lettuce, French Beans, or any other low-growing crop between the rows the first season.]

2928.—**Leaf-mould.**—*J. B. H.*—The littery material found under Fir trees is of more harm than good in the garden. Leaf-mould is only good when made from Oak, Lime, Elm, and similar trees. The clearing of old ditches in which leaves have accumulated for years is excellent material.

2929.—**Tomatoes.**—*At a Loss.*—If you have no glass accommodation you can only get plants next year by raising them from seed or purchasing, the latter being the best method, as you may then get plants to put out at the end of May, whereas if you raise them yourself they will not be ready till the end of June or later, and the crop will be late in proportion.

2930.—**Keeping Plants through the Winter.**—I took a house with a large garden last March. I have it fairly stocked with choice Dahlias, Calceolarias, Geraniums, Verbenas, Phlox, and Heliotropes. What ought to be my course now, so as to propagate cuttings of these for next year, as I don't want to buy any more, these having cost me £10? I have no glass; could I keep the old plants indoors through the winter in a warm spare room, or had I better run up a cheap lean-to conservatory, and have an oil stove? If the old plants are not to be kept, how am I to take cuttings? and when and how am I to treat them?—AT A LOSS. [When the tops of the Dahlias show signs of decay, and before very severe frost occurs, lift the roots, cut off the tops to within 1 ft. of the roots, and store the tubers in any shed or room from which frost is excluded, burying them in dry soil, sand, or even ashes, and plant out again in May. Cuttings of Calceolarias may be taken in at the end of October, and struck in firm sandy soil under handlights or in a frame. Cuttings of Geraniums may be put in sandy soil now, and if potted early in October, and placed in a warm window, and kept rather dry at the root, will keep through the winter. The old plants may also be potted and kept in a similar position. Verbenas and Heliotropes may be struck now, or old plants may be cut back, and be taken up and potted in a few weeks, and kept likewise in a warm frame, or even a window. Having no glass, however, your best way would be to sacrifice the few pounds you have spent in these plants, and stock your garden with a variety of good hardy plants, which will cause no trouble but that of planting well, and give a bloom far superior to that obtained from "bedding" plants, at least, under the conditions named above, from spring to autumn.]

2931.—**Moving Fruit Trees.**—When is the earliest time at which fruit trees may be moved with safety?—FANNYCUMS. [You may move them at once. Carefully remove the soil 3 ft. or more round the trees with a steel fork, so as not to break the roots. Have holes large enough to receive the roots without cramping in readiness; do not plant too deeply; 6 in. below the surface will be plenty. After planting mulch with rotten manure, and stake the trees to prevent wind waving. If the ground is very dry, give a good soaking with water.]

2932.—**Plants for Covering Walls under Greenhouse Stages.**—*P. S. O.*—Some of the small growing Ivies, the creeping Fig (Ficus repens), or Veitch's Virginian Creeper (Ampelopsis Veitchi) would succeed.

2933.—**Apple Trees from Branches.**—I have an Apple tree similar to the Burr Knot mentioned in GARDENING ILLUSTRATED of last year, No. 12, p. 189, which I wish to cut down and make several small ones out of it by division of branches. Would you tell me the best time for doing this? also give some limits as to the way of planting them.—FANNYCUMS. [We would cut off a few of the branches just below the root-like excrescences at once, and plant them firmly 4 in. to 6 in. deep in a border of good soil. In February put in the others; you will then see which time is best.]

2934.—**Moving Gooseberry Trees.**—*Fannycums.*—These may be moved at any time from October till February. Cuttings are usually put in in February or March when pruning is being performed, but you might remove some of the shoots, which are not needed when you lift the plants, and insert them in firm soil. The shoots should be from 6 in. to 12 in. long.

2935.—**Indian Acacia.**—I have an Indian Acacia in my garden in Dorsetshire; will it stand the winter out-of-doors, or must I pot it and take it in?—R. C. C. [We presume you mean Acacia arabica. If you have only one plant you had better take it indoors, or give it some protection. If you have more than one, leave one out all winter by way of experiment.]

2936.—**Plants in Cold Greenhouse.**—Will Camellias answer in a glass house not heated in winter in the midland counties? and would any other plant besides Azaleas answer in such a house?—A. K. [Camellias would succeed, so would Azaleas, also the choicer Rhododendrons, Deutzias, Hydrangeas, Fuchsias, some of the hardier Passion-flowers, Jasmines, Clematis, and a host of other fine plants.]

2937.—**Seedling Eucalyptus.**—*J. B. N.*—The seedlings should be potted and kept in a frame or greenhouse all winter, and they will make good plants for putting out in the open border in May.

2938.—**Suckers on Rose Trees.**—My Thoresbyana climbing Rose throws up strong, pinkish, watery shoots, very thick ones, besides long, thin, hard-wooded shoots. Which ought to be pruned off?—A NOVICE. [The strong shoots are the suckers, which should be cut off.]

2939.—**Ivy for Front of House.**—Which is the best and quickest growing Ivy for front of house facing south-west? and when is the best time for planting it?—R. H., *Norwood*. [Irish or the Algerian plant. Plant in September.]

2940.—**Caterpillars.**—My plants are being ruined by swarms of caterpillars, chiefly green, but there are several kinds. They have eaten off a row of Pansies, destroyed a fine Azalea and Harrison's Musk. Indeed, nothing in garden or greenhouse is quite free. What can I do? I have watered with paraffin and water; but this if weak makes no difference; if strong, blackens and destroys the foliage.—A. B. C. [Caterpillars are remarkably numerous this year, and there is no cure that we know of, save that of diligently searching for them morning and evening. A circle of soot put round a plant will keep them off a little, and a good plan is to strew the ground with Cabbage or other leaves of which they are fond, and examine them frequently.

2941.—**Striking Cuttings.**—I have a large bed of Heliotropes and two of Verbenas of different sorts, and I should like to save them by cuttings, but I should like to see some comment on striking cuttings of them.—GEORGE BAILEY. [Cuttings of both Verbenas and Heliotropes will strike freely at this season of the year if placed firmly in well-drained pots of sandy soil placed under a hand-light, or in a frame shaded from the sun. They must be taken indoors during winter. Young-growing shoots only should be chosen as cuttings. If you cut back a few plants they will soon give you plenty of cuttings, and you might also dig such plants up and pot them.]

2942.—**Transplanting Chrysanthemums.**—*G. B.*—Plants of these struck in March last may be planted out now if desired, that is, if they are intended to remain out-of-doors altogether.

2943.—**Pruning Raspberries.**—*Wood B.*—If growing in rows the young canes may be left 12 in. to 15 in. apart. Cut out all the old canes when the leaves begin to fall. The side shoots of the young canes, if any, may remain.

2944.—**Plants in Cold Frame.**—I have just completed a cold frame, 7 ft. by 4 ft. 6 in., facing south, consequently it gets a good deal of sun. My garden is just on the outskirts of a midland town. I should be glad to know the names of any plants I can keep in it during the winter, and so give more room in a small greenhouse.—AMATEUR, *Derby*. [If you will state what plants you have we can tell you if you can winter them in the frame.]

2945.—**Wintering Pelargoniums and Carnations.**—Would seedling Pelargoniums and Carnations be likely to do well through the winter if kept in a rather draughty living room?—INDOCTUS. [They might exist; they would not be likely to do well.]

2946.—**Sowing Annuals.**—Is it well to sow half-hardy annuals generally, and Phlox Drummondi in particular, in the autumn?—INDOCTUS. [Certainly not; sow hardy annuals in September, but half-hardy ones would be killed.]

2947.—**Charge of Dishonesty against Advertisers.**—I wrote on the 29th of April, 1880, to a person advertising in GARDENING for a packet of seed, for which I enclosed thirteen stamps, and I received no answer. I wrote again about three weeks afterwards, and still received no answer. Can you give me any reason why a man should publish his name in your paper to deceive the people?—THOMAS CLARK. [You do the person to whom you sent for the seeds a gross injustice. The fault lies in you not sending to him your correct address. We have in our possession letters which prove that the seed was sent to you and your letters answered, but were returned through the Dead Letter Office. If you will send us your correct postal address, you will doubtless get your seeds and further explanation.]

2948.—**Emptying Cesspools.**—Is there any way of preventing a smell from the contents of a cesspool previous to spreading it over land? The land in question is in the centre of a town, and I am told that the sanitary authority could attack the owner if there is any smell, which there would be for a day or two after the contents of the cesspool were pumped out and spread over the kitchen garden and fields.—S. K. T. [The contents should be mixed with dry, finely-sifted soil previous to being carted away. If peat soil all the better. Have a large heap and make a basin in the centre to hold the sewage, throwing over it and also in the cesspool a few shovelfuls of dry earth as the work proceeds.]

2949.—**Planting Apple Trees.**—I want to shade a window from the sun by means of an Apple tree. What sort would be the best, and the time for planting? The soil is of a clayey nature.—F. BARTON. [Cox's Orange Pippin, Wellington, and Tower of Glamis are good kinds. Plant in September or October.]

2950.—**Canary Creeper not Flowering.**—*Newt*—Being in a glasshouse, you must give it all the air you can, and no doubt you will have a good bloom by and by. The plants were probably planted late; they are, however, sure to flower.

2951.—**Planting Passion-flowers.**—*H. B.*—You may plant at once if you procure good strong plants, but it would be better to wait till April or May, as then the plants get established before the following winter. We are, of course, assuming you mean the hardy Passion-flowers to be planted out-of-doors.

2952.—**Giving Azaleas Fresh Soil.**—*A. E., Guernsey.*—Azaleas are best repotted when they go out of flower and new growth commences.

2953.—**Begonias not Growing.**—*A. E., Guernsey.*—In spring you should shake the soil from the bulbs, and pot them in fresh soil, and in pots just large enough to admit them. Place them in a warm part of the greenhouse and keep moist. Shift into larger pots when they get nearly root-bound.

2954.—**Fig Tree on South-east Wall.**—I have a plant well established and which has made good wood, and having now at every joint, or rather at the base of every leaf, a small Fig in regular gradations of size, from a Cobnut to a small Pea. Should all these be cut away?—C. E. [Leave them on the plant. The largest will probably drop off in spring, but the small ones may ripen next summer.]

2955.—**Soil for Geraniums.**—What is the best compost for Geraniums from cuttings just nicely rooted?—FIDO. [Sandy loam without manure.]

2956.—**Prolonging the Blooming of Fuchsias.**—Having a splendid show of these plants, I am desirous of preserving them as long as possible. They are in a properly built and heated conservatory. Several of the buds drop each night; they are watered daily. Can you advise me how to prolong their blooming? [Give plenty of air, water thoroughly when the plants require it, not daily whether they want it or not, and give a little weak manure or soot water, or a pinch of Clay's Fertiliser, or Standen's Manure occasionally. If you cut back the shoots of a few of the plants they will break into fresh growth, and give a good bloom later on.]

2957.—**Strawberries for Succession.**—I should feel obliged if you would tell me the best sorts of Strawberries to plant, in order to secure as long a succession as possible?—J. E. VAUX. [The following are all excellent sorts, and will give a long succession of fruit. They ripen in the order named: 1, Keen's Seedling or Héricart de Thury; 2, President; 3, Sir Joseph Paxton; 4, Sir Charles Napier; 5, British Queen (if your land is stiff loam); 6, Elton Pine.

2958.—**Blighted Grapes.**—*Mr. C. Colne.*—Your Grapes are mildewed. There is no hope of saving them this year. We would advise you to cut them off at once, and dust flour of sulphur on the leaves which are affected, and give all the air possible. The cause of the mildew is keeping plants in the house, and too moist a temperature. Next summer put the plants outside, and maintain a drier atmosphere in the house, and give more air during fine weather. When wet weather sets in, use a little fire-heat, giving air at the same time.

2959.—**Heating Greenhouse.**—Having built a small lean-to greenhouse, 19 ft. by 8 ft., against a wall, on the opposite side of which is the kitchen fire, could you tell me the best means of heating the same? Is there any simple means of heating it from the kitchen fire? If so, what sort of grate is required?—SCOT. [If you have a kitchener the boiler of which is fed from a cistern, you can easily have pipes attached to heat your greenhouse, but if only an ordinary open grate with boiler fed at the lid as required, your best method would be to have a stove for the greenhouse, unless, indeed, you care to have a kitchener put in.]

2960.—**Gloxinia Dying off.**—I had a beautiful blue Gloxinia from a nursery, and very soon after I put it in my conservatory it faded and drooped. I have repotted it and given it plenty of water until the last seven days, when I forbore. What is the cause?—FIDO. [You repotted and then killed it with water.]

2961.—**Calceolaria Drooping.**—Why does my Calceolaria droop? It has plenty of water, and is in a good conservatory.—FIDO. [Careless watering probably.]

2962.—**Green-fly and Paraffin.**—Some seedling Cinerarias had the green fly. I therefore put on them some paraffin and water (a wineglassful of the former to 2 gals. of the latter). The green fly are most effectually killed, and so also are the Cinerarias. Could you tell me where I have made the mistake?—G. E. T. [In not keeping the liquid well mixed, and using it too strong on young and tender plants.]

2963.—**Gloire de Dijon Rose.**—A large Gloire de Dijon against my house has run up to head about 10 ft. high, and bare at the bottom. Would it do to cut it down? If so, when is the time, and how near the ground ought it to be cut down?—G. E. T. [We should not advise you to cut it down if you want it to bloom.]

2964.—**Violas Cut Down.**—Will Violas that have been flowering all the summer, if now cut down, make as good a show next year as plants fresh struck?—G. E. T. [Yes, but the flowers will be smaller.]

2965.—**Outside Window Gardening.**—In a recent number there was an article on outside window boxes. We have had four sets of boxes ordered to keep up successional bloom. Will you kindly state which are the best seeds to sow for that purpose? We have no frame, and our back garden is nearly south. The boxes will be in windows facing north-east.—A SUBSCRIBER. [Plant one set with Pansies, double Daisies, Aubrietias, Violets, Forget-me-nots, Primroses, and other spring blooming plants. Another set sow with seeds of hardy annuals, such as Candytufts, Nemophilas, Collinsia bicolor, Godetias, Limnanthes Douglasi, &c. Keep the other two sets till spring, and sow one with annuals similar to those mentioned, and plant the other with Lobelias, Ceraniums, &c.]

QUERIES.

2966.—**Ivy for Fernery.**—Will any reader kindly give me the name of an Ivy most suitable for covering a wall in a Fernery?—C. O.

2967.—**Growing Bulbs Indoors.**—Will some one please tell me the names of the best six single Hyacinths for growing in glasses for show? also the best six double Hyacinths for growing in pots in a house where gas and fires are used constantly? also the names of a few bulbs which could be easily grown in the house, and their treatment?—ROSS.

2968.—**Plums Cracking.**—I have a very fine Plum tree, the name of which is doubtful, though I think it is called the Denbigh Seedling. It bears large, round, pinkish-red fruit, frequently weighing 3 oz., but just when the fruit is ripening it invariably cracks, and exudes a kind of gum. Can any one give me the reason, and any preventive?—J. B. H.

2969.—**Plants under Trees.**—What should I sow either now for spring, or in spring, to do well under trees? The bed has a southern aspect, but is a good deal overhung, and in wet weather the trees drip on it. It has a good slope; the soil rather heavy. Also to grow on each side of a drive running south, but trees on each side meeting overhead in places. I should be satisfied if I could get a border, as there are Laurels, &c., down each side.—BEGINNER.

2970.—**Damage to Garden.**—Can any one tell me the law as regards the following: The owner of a stable and garden lets the stable to A— and garden to B—, no fence between stable and garden. The horse belonging to A— gets out and runs over the garden and eats a great portion of crops and damages the rest. Can B— claim damages of the owner of property for not having a fence? or must he claim it of A—?—PAINTER.

2971.—**Wintering Coleuses.**—I have some Coleus cuttings which I wish to save through the winter. Will any reader suggest a plan whereby I can save them? My greenhouse is not heated enough for them.—ENQUIRER.

2972.—**Cucumbers not Fruiting.**—I had a Cucumber plant in a large box trained up a pole to the roof of a greenhouse, and is healthy looking, but most of the buds are minus fruit, and what fruit there is only attain the size of 1 in. long, then turn yellow, and finally drop to the ground. Can any reader tell me the cause? Temperature of house 65° to 80°.—ENQUIRER.

2973.—**Cactus Cuttings.**—Will some one inform me how to treat my Cactus cuttings? They were put into half of a small tub last autumn, and they are now sending out side shoots. Do they require to be potted off singly now? and what temperature do they require through the winter? Also what kind of compost will they thrive best in? I should like them to bloom next summer if possible.—ENQUIRER.

2974.—**Drying Flowers.**—I am anxious to make a collection of flowers from each place I visit; will some one kindly inform me the best way of pressing and drying them?—JANET.

2975.—**Feeding Pumpkins.**—Pumpkins are fed with milk by the Dutch to increase their size; can any one tell me the proper *modus operandi*? I have failed with Vegetable Marrows, Mammoth Gourds, and Turk's-heads. I fed them through the stalk with a glass tube. They grew larger, but rotted inside?—T. C. P.

2976.—**Drying Fruit.**—Will some one be kind enough to say how this is done? and what sorts of Apples and Pears are most suitable for preserving by the drying process? Last year (Aug. 16, 1879, p. 503) "J. L." speaks of it being done in ovens in a very simple way; will he kindly give a description of them, or say where they are to be obtained if of any particular make?—OLD SOLDIER.

2977.—**Cucumbers Being Eaten.**—Could any reader inform me what is the matter with my Cucumbers? As soon as the fruit makes its appearance, it seems to be eaten off, as I find them upon the bed eaten through about the middle; the plants are to all appearance in a robust healthy state and free from insects?—PLUMBUS.

2978.—**Water Bouquets.**—I should be much obliged if some one would tell me how to make a water bouquet, and with what flowers?—SYBIL.

2979.—**Moles in Gardens.**—We are very much troubled with moles in our garden. Can any one tell me how to get rid of them? I have tried to trap them, but cannot succeed.—WM. SYDENHAM.

2980.—**Gloxinias for Autumn Flowering.**—Will any reader kindly inform as to the treatment of autumn-flowering Gloxinias? I am at present growing them in a frame, which I heat at night with a small paraffin lamp. Would they grow in a room heated in the same way better? I open the frame to admit plenty of air. Please say if this is the proper mode of treatment.—R. POLLARD.

2981.—**Hydrangeas not Flowering.**—Can any reader tell me the reason why my Hydrangeas have failed to flower this year. I live in the Isle of Wight, where they grow to large bushes, and I have three or four of such bushes in my garden. Last year they were one mass of bloom, but this year, though the foliage is in splendid condition, and the plants apparently most healthy, only one bloom has shown itself. The gardens round mine are filled with fine blooms, hence the weather can have nothing to do with the matter. The plants are of course cut back every year after flowering.—SUBSCRIBER.

2982.—**Berry Bugs.**—Is there any cure for the minute scarlet insect called in this part of the country the berry bug? Several members of my family are very painfully afflicted by its attacks, and we have tried many remedies, but hitherto unsuccessfully. I should be greatly obliged if any reader would kindly answer this, and give any remedies they may know of to alleviate the pain these creatures cause. They are got either by going through long Grass, or from the garden shrubs, &c.—THOS. LOCKHART.

2983.—**Propagating Clematis Jackmani.**—Will any of your readers tell me the best method of propagating Clematis Jackmani? I have a large plant on a wall in full bloom, but do not see any growing ends. Will they come after blooming?—J. S. L.

2984.—**Begonias Going to Seed.**—Can some reader tell me why my Begonias form large seed vessels before they come into bloom, and then only last a day or two in flower? It is only lately I noticed it on some of the plants.—GLENVAR.

2985.—**Rose Shoots Nibbled Half Through.**—I am obliged to "R. T. N." (Ans. 2719) for his suggestion, but it does not apply. Neither leaves nor buds are bitten at all; they droop and wither after "their stems" are so much eaten away. Plenty of centipedes and black beetles infest the soil, but "H. B." is not fortunate enough to detect the offender in the act, or to entrap them wholesale.—H. B.

2986.—**Potatoes in Pots.**—Will some reader of GARDENING experienced in growing Potatoes in pots kindly give a few instructions as to the best sorts to grow, the time to plant them, the best soil to use, and any other information it may be necessary to know for their successful cultivation? and also whether with proper attention and a good house to grow them in they may be considered a remunerative crop to grow?—A. P., *Maidstone*.

2987.—**Russian Violets.**—To make Russian Violets blossom profusely during the autumn and spring, I have heard that it is well to take the plants up and starve them during the late summer. Will any one who has had experience in so treating the plants tell me how and at what time this is best done? My Violets (Russian and variegated blue) have abundant foliage, but produce but few blossoms.—L. R.

2988.—**Fuchsia splendens.**—What shall I do with a young plant of Fuchsia splendens? I bought a rooted cutting which grew vigorously for a time, then the leaves began to fall off, and it grew straggly and weak, and has not bloomed. A young cutting from it has gone just the same; it is in a cool greenhouse? Is it better to dry Fuchsias off when done blooming? Those I dried off last year have bloomed too late, and some have not bloomed at all.—A LEARNER.

2989.—**Plants for Frames in Winter.**—I have two frames, one of which has had Cucumbers in it all the summer. Can any one suggest what would be best to plant to succeed the Cucumbers? The other frame is new, and I wish to preserve cuttings of flowers in this for the winter. Which would be the best way to make up the bed? I have some fresh manure. Also will a concrete bottom be objectionable?—C. H. D.

2990.—**Botanical Drying Paper.**—Drying wild flowers.—Will "Ped" (2296), in his recommendation in your issue of July 31 last, kindly state where botanical drying paper is procurable? Is it not simply the rough thick drying paper used in ordinary letter coping books? Will it also preserve the colour of the flowers?—NOVICE.

2991.—**Vine Suddenly Dying.**—I have a Vine (Pearson's Golden Queen) which has been planted four years, and last year it pushed to the top of Vinery (18 ft.), but we had an accident last winter and broke it down 8 ft.; but it has again pushed to the top good strong wood, and has about 4 lb. of fruit on it just changing colour, but about three weeks ago it began to flag, and now I am afraid it is quite dead. The border is outside, with a small one inside in which the Vines are planted. I have watered the inside border with manure water. There is a stack pipe just over the place where the roots should enter the outside border, and I am afraid the water washed over these from the heavy storms we had the week previous to the time that I first noticed it. Would that cause so sudden a death? The other Vines have each a good crop, and are looking well.—J. CARTER.

2992.—**Hardy Edging Plants.**—Can any one give me a list of edging plants for beds that will be permanent? Are Sedums and Stonecrops quite hardy? and would this be the time to plant them?—EMMA.

2993.—**Blooms of Begonias Falling.**—My Begonia showed well for flowering, but just as the buds were about to open all the leaves and buds fell off, leaving the plant quite bare. Last season it was the same. It had previously flowered well. Can any one tell me the cause, and suggest a remedy?—C. H. E.

2994.—**Preparing Ground for Potatoes.**—I have a small piece of ground (about 30 ft. by 12 ft.) in my garden on which I want to grow some Potatoes. The soil is of a clayey nature, and I have been growing Cabbages and Peas on it. Will some one kindly inform me what kind will be best to put in (a very early one), and when? Likewise, can I use the ground for anything else before the time? If so, what? Or would it be better to let it lay the winter turned out?—H. BARTON.

2995.—**Peaches and Nectarines Failing.**—My Peaches and Nectarines in an orchard house have done very well for some years, but this year the leaves are withering and falling, and the fruit drying up and coming to nothing. What is the cause? I can only think of one cause: they have been watered with manure water, but this has been done for two or three years, the same as to the Vines in the other part of the house, which are doing very well.—J. D.

2996.—**Striking Roses in Water.**—Will "S.M.M.," who suggests an easy way of propagating Roses from cuttings, kindly say how he pots his cuttings? I have many times obtained rooted cuttings of Roses in bottles of water, as he says, but have never succeeded in establishing such cuttings in pots afterwards, though by reason of the tenderness of the roots the greatest care has been used in potting. The roots produced by means of the water have never, in my case, taken to the other element—earth.—W. H. M.

2997.—**Nasturtium Pods for Pickling.**—Can any one tell me if the seed pods of the dwarf Tom Thumb Nasturtium may be safely used as a pickle in the same way as those of the larger or climbing kind are?—SUBSCRIBER.

2998.—**Cankered Roses.**—I have a large Maréchal Niel which has a canker in the back close to the root; how can I best get rid of it? The tree used to bear between 200 and 300 blooms, but now bears scarcely any.—T. C. P.

2999.—**How to Improve Lawns.**—I have a newly-made lawn; in some places it is sunken and almost bare. Can any one tell me how best I can improve it?—A LEARNER.

3000.—**Gloxinia crassifolia.**—Having a number of seedlings of the above, I shall be glad to be informed as to their future treatment, including soil, &c. They are now about 1 in. in height.—SEVENOAKS.

3001.—**Carnations and Picotees.**—I am very anxious to grow some good Carnations and Picotees which will bloom next spring in a conservatory. What would be the best way to set about it? I have sown some Picotee seed and struck several cuttings of Carnations, but I should like to know what kind of soil they like best: whether I must keep them in a hot or cold frame or greenhouse during the winter. Can I procure a yellow or lemon-coloured variety? I have now only red, white, pink, and pink edged with white.—J. P.

3002.—**Ageratums not Flowering in the Usual Way.**—I am rather fond of these as a plant for the mixed border, but for the last two years I have not had them in their true character. They turn out a dense mass of leaves almost branchless; the bloom came late, and the little there is of it are without stems, and buried close to the leaves. Can any one tell me the cause of this? Other plants, such as Geraniums and Verbenas, have come out all right in the same beds.—SUBSCRIBER.

Gooseberry Caterpillar.—I have heard that in Sutherland they bind branches of Broom round plants attacked with caterpillars, and it quite banishes them and keeps whatever plant it is round clear. Will some one try this simple remedy and report the result?—AILENROC.

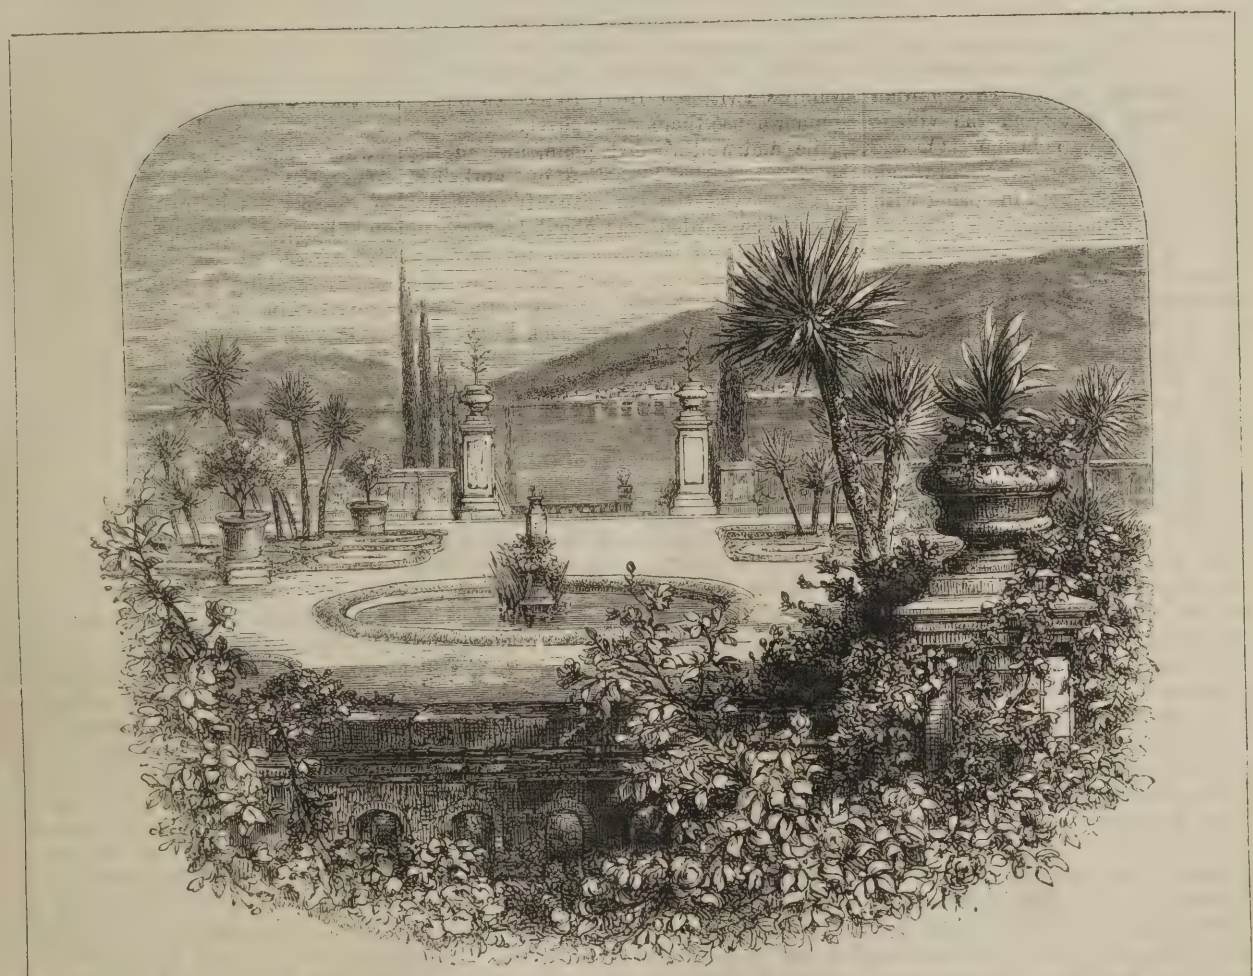
GARDENS IN HOLIDAY TIMES.

BY A LADY.

COWLEY, writing to John Evelyn, whose literary fame rested at that time on his recently published "Sylva; or, a Discourse on Forest Trees," says:—"I never had any other desire so strong, and so like covetousness, as that one which I have had always—that I might be master at last of a small house and large garden, with very moderate garden, among weeds and rubbish, and without that pleasantest work of human industry—the improvement of something which try—the improvement of something which we call (not very properly, but yet we call) our own." This is a most natural wish, though I must say that, perhaps, the pleasantest hours of my life have been spent in the gardens of others. There one has none of the cares and responsibilities which a sense of ownership brings, no regrets over be turned into an exhibition ground for tricolored Geraniums, Echeverias, Aloes, and other things well enough in their places, but which offered no real satisfaction to a true lover of Flora. These thoughts sometimes interfere with the enjoyment of one's own garden; but it is far otherwise when, either alone, or in pleasant and congenial company, we spend a quiet hour in the garden of a friend; memory recalls many



A GARDEN IN LAKE MAGGIORE.

conveniences joined to them, and there dedicate the remainder of my life only to the culture of them and the study of Nature. But several accidents of my ill-fortune have disappointed me hitherto, and do still, of that felicity; for, though I have made the first and hardest step to it by abandoning all ambitions and hopes in this world, and by retiring from the noise of all business, and almost all company, yet I stick still in the inn of a hired house and the blindness which caused us to plant that Cupressus Lawsoniana in that barren spot where it could not possibly do well, no lamentations over the careless manner in which the gardener transplanted that Magnolia, so as to render its flowering during the summer more than doubtful; no vexations, no remorse at having been persuaded into allowing the greater part of a garden which might have been a paradise of sweet-scented plants and old-fashioned flowers to "times of refreshings" like these. I speak not now of the stately pleasure grounds, when, as the learned author of the "Anatomy of Melancholy" says, you may "walk amongst orchards, gardens, bowers, mounts, and arbours, artificial wildernesses, green thickets, arches, groves, lawns, rivulets, fountains, and such-like pleasant places, or disport in some plain or park;" and then he proceeds to describe the Prince's garden at Ferrara, and

quotes S. Bernard's account of the garden of his monastery. Very fine on paper are these descriptions, but, as when Don Pedro wooed the fair Beatrice, and prayed her to take him for her husband, she replied, "No, my lord, unless I may have another for working days, for your grace is too costly to wear every day," so I turn from these and dwell with a feeling of relief on the recollection of some homely spot, where old-fashioned flowers thrive well, and you can pluck them to your heart's content; where trees and shrubs (planted in no formal manner) cast a peaceful shade on grassy walks, where you are not tormented by thinking you are called upon to admire something; here nothing is obtrusive, and some feeling of the repose of Nature steals over you as you walk alone.

There is such a garden (probably one among numberless others) on the borders of the Mediterranean Sea. It is in a fair Italian town, as yet unhaunted by tourists. Cook is a power still unknown. No one speaks English. There are no amusements in the proper sense of the word—no casino, no theatre, no gaming tables. This garden stands "somewhat back from the village street," the Strada Borgo Marino. On one side you approach it by an Olive wood, whose shaded turf is covered in spring with scarlet and lilac Anemones, the fragrant Narcissus, and the star-like flowers of the white Periwinkle. As you enter the gate out of the wood, you traverse a long avenue of Orange trees, covered with ripe fruit, with here and there a gigantic Palm. The Oranges are for the most part Mandarins; the trees are beautifully shaped, the glossy green of the leaves forming a fine contrast to the golden fruit. Leaving the avenue, you pass into the garden proper, which is not large in extent, though the tall trees and vegetation deceive the eye as to its size.

There are no formally planted beds, but Roses, Stocks, Violets, and Mignonette grow here in what the Irishman called "nate confusion." Here a Palm with twisted stem and yellow Dates hanging in clusters shades a rustic seat, while groups of Aloes fill up the ground below. Stocks and Roses were the chief flowers in the month of March; but Violets, particularly the light double ones, were most fragrant. There were numerous patches of Pinks, while Virginian Stock and other pretty annuals made the odd corners of the garden gay. Here and there grow large Oleanders, not, however, yet in bloom. There are many fan Palms, with their broad-spiked leaves, and other fine trees, principally the Caroub, with flowering shrubs that were quite new to me, and of whose names I am ignorant. On one side is a rockery covered with Mosses and large plants of the Maidenhair and other Ferns. The "old-fashioned country seat" has likewise its covering of creepers, Passion-flowers, Gloire de Dijon, with other Roses, interlaced with the branches of a luxuriant Vine. Such was the garden in which the writer spent many hours in every week this spring entirely undisturbed. No gardener was ever to be seen, and the distant hum of life from the town some way off hardly broke the stillness. No one ever appeared to walk there; the silent inhabitants of the villa seemed to have left this garden to take care of itself. It was like "the land where it was always afternoon." The ground gradually rose from the gate you entered until you reached the other door, which led into the upper part of the town, and opened into the Strada Romana. From this spot you looked down on the sea, though too far off to hear anything of the fall of its waters beyond a distant murmur. Far away to the west the snowy peaks of the Maritime Alps seemed to touch the clouds, while below white villages nestled on the hillside amid the dull green of the Olive woods; here and there a tall Campanille broke the line, and sometimes a distant bell was distinctly heard in the quiet air; on the east a tall cliff and a rocky shore, with here and there shining sands, with picturesque fishing boats, the gay-coloured dress of the fishermen adding colour to the scene.

After all, the garden which I remember with the most pleasure is one in a midland county. No particular beauty marked the situation—no mountains, no river, no very extensive prospect. It occupied the slope of a hill, and from the top, where "the swallows twittered from the straw-built" summer-house there was a lovely view of a fertile and well-wooded plain, and in the far distance the long line of Yorkshire hills preserved the landscape from monotony. The garden was about $1\frac{1}{2}$ acres in extent; part of it was given up to vegetables, and on the south side the wall was covered with well-trained fruit trees —Peaches, Nectarines, Apricots, Pears, and Plums. I never saw anywhere finer crops than those produced here. No pains were spared to render this little spot not only pleasant, but exceedingly profitable. But I am speaking of things as they were twenty years ago, and the science of gardening has made great progress since that time. The north wall, to which Morello Cherry trees were trained, divided the garden from a large orchard; all the length of this wall was a border, full of "April's first-born flowers"—Violets, Primroses, and Lilies of the Valley. Here they flourished, for they were not disturbed; from year to year they went on bearing masses of flowers, for it never occurred to the gentle and bookish master of the old house to think of allowing them to be dug up to make room for modern favourites. He would as soon have thought of sending his pet copy of Pietro della Valle's works to be divested of their old Italian binding and re-clothed in modern dress as of allowing one of his Lilies to be moved. True, he was no botanist, and hardly knew the Latin names of his plants, but he loved them well. How often have I seen him, with some ancient folio in hand, treading the Grassy walks, ever and anon stooping to pluck a flower, and lay it for a mark in "the chronicle of wasted time."

Many a discussion had he with the old gardener, who treated him with reverence, excepting when he ventured to differ from him on some point connected with gardening. "Rakes" was a thoroughly practical man; little book learning had he, and made awful blunders in most of the names of his plants; not only did he mispronounce them strangely, but he went out of his way to write them as unintelligibly as he possibly could. Some of his mistakes were amusing. "Rakes, I do wish you would label these new Roses."—"Ay, ay, sir; I'll libel them."—"Rakes, what do you call that fine shrub?"—"Why, master Duke, your grandfather do say it is a Jupiter tree" (Juniper).—"Rakes, it is such a pity you are a Methodist; now, if you would go to church you would hear such music. What an anthem we had the last time grandfather preached in Aldwark church."—"Nay, nay, sir; I don't think nowt at all o' your hanthems; they're all backards and forrards, and up the middle and back again, and when you think you've done wi' 'em they just sets off, and begins all over again. I can't abide 'em. Gi' me a good ranting hymn and have done wi' it. Its just as if i'stead o' sowing these 'ere Peas, I wor to spend my time dancing backards and forrards on a Cabbage leaf." But Rakes was well up in the practical part of his work; how proud was he of the part of the garden specially given up to Roses and other perennials. From the straw summer-house, a long grassy walk, shaded by Nut trees and Portugal Laurels, whose branches formed an arch, led down hill to the large Grass plot in front of the old house; what a walk that was! The July sun could hardly penetrate the thick foliage overhead; the path was wide enough to allow of rustic seats being placed at intervals; and here, if you strayed in on a fair summer afternoon, you would find the master smoking a quiet pipe, and always ready to greet a friend.

On each side of the walk grew masses of Roses, Pinks, Carnations, Canterbury Bells, Phloxes, with beds of Stocks and Mignonette. The scent was something to remember. Beyond these, in spring, towered tall Lilacs, Laburnums, Snowballs, and Syringas. The large Grass plot was not cut up into beds, but on one side, not far from the south walk, Apple trees, trained as espaliers, divided it from the border given up to the wall trees, while in a quiet corner there was an arbour formed of a carefully-trained Jargonelle Pear tree. It was fitted up with seats and a table; many were the luncheons and teas which took place here.

The Grass plot was a carpet of velvet, soft and mossy, and always beautifully kept; it sloped almost down to the house, only divided from it by a broad paved walk. The house itself was of the time of Queen Anne, and not remarkable for any beauty; but Nature, pitying the poverty of art, had clothed it in a lovely dress of climbing Roses, Jessamines, and Honeysuckles. They nearly covered the front which opened into the garden; they garlanded the old windows, peeping into the quaint low-ceiled rooms, and filling them with perfume. A rustic porch protected the door; on each side of the porch were three shelves, which were filled in summer with pots of Balsams, Musk, and a trailing Campanula, whose pale blue flowers, hanging from the lowest shelf, touched the ground. Even early in spring there were Crocuses, Snowdrops, and Hyacinths, with other children of Flora who "come before the swallow dares." Such was a garden in the Midlands some twenty years ago, but who can arrest "Time's thievish progress?" After an absence of fifteen years in a distant colony I returned to England, and hastened to re-visit the spot I had so often seen in my dreams. Sad news had, it is true,

travelled across the sea—tidings of loss and change; but I was hardly prepared for the entire transformation of the old home. A wealthy ironmaster had bought it, and had, of course, immediately set about the work of renovation. Little was there to be seen of all I had fondly remembered. The house was curiously decorated and converted into a cottage *orné*, and the garden cut up into beds filled with glaring "bedding plants of modern times."

DAMAGE DONE TO GARDENS BY COWS.

In Gardening of July 31 a correspondent asks a question on this subject, and I have been expecting some abler pen than mine would have made answer to this question before now. Cases of this description are constantly before the Courts, and owners of cows, horses, and sheep are very often greatly astonished at the heavy damages they have to pay for their animals getting into their neighbour's meadow or Corn when it was the neighbour's fault for not keeping his fence in good order. The law is, that the owners of cattle must fence their beasts in, and if they get out of the field the owner of the cattle, sheep, or horses is answerable for all the damage they do, irrespective of the ownership of the fences, except in very special cases. I have just happened to come upon the following case in point:—

"Samuel Pollitt, farmer, of Thrintoft, was sued by John Lightfoot, farmer, of the same place, for the sum of £5, damage done to a Grass field by the defendant's sheep breaking into it. Mr. J. I. Jefferson, solicitor, Northallerton, appeared for the plaintiff. In May the defendant bought a number of sheep and put them into a field adjoining the plaintiff's. After they had been some time in they got through the fence into plaintiff's field, and continued to do so during the month of June and part of July. Witnesses were called who proved seeing the sheep in the plaintiff's field, and that the fence belonging to him was kept in good repair by him. Witnesses also stated the amount of damage done. The defence was that the defendant could not keep the sheep out of plaintiff's field on account of the bad state of his fences. His Honour ruled that it was the duty of the defendant to see that his sheep did not stray, and gave a verdict for the plaintiff for the amount claimed, with costs."

The leading case on the question is "Boyle *v.* Tamlin," and there it was laid down that "when two persons have adjoining fields and no hedge or fence between them, then each must take care that his own beasts do not trespass on his neighbour, unless one proprietor has acquired a right by grant or prescription to have the boundary fence maintained at the expense of such adjoining proprietor." There is an exception in the case of a fence by the side of a highway if cattle are being driven down the highway, but not if they are straying. A Solicitor.

THE SLUG.

Until lately I was not aware that there could be anything interesting in the slug. His personal appearance is not generally considered prepossessing. His locomotion is miserably feeble, not to say sluggish, and notwithstanding that he leaves in his trail a bright silvery line, the association of ideas robs even that of any beauty which it might otherwise possess, whilst his ravages among our choicest and tenderest plants bear witness to his insatiable appetite.

In the autumn of last year one of these marauders, a fine powerful thoroughbred grey, had insinuated himself into my greenhouse, and by his nocturnal attacks caused the solid squares of my promising young recruits to get sadly demoralised; but my patient vigilance has at length been rewarded. I came upon my enemy one evening wending his way, "without a thought and without a care," in the direction of my seedlings. Every amateur will understand and appreciate my feelings, as when gazing on my foe I muttered—

"There is not to reason why,
There is but to do and die."

Still the question of how best to kill the slug is not so easy of solution as the inexperienced might suppose. I have tried a brickbat dashed into him, but without appreciable effect; true, the garden roller is effectual provided it is of smooth iron and the path firm; still, it is unsatisfactory, and the sole of the boot is objectionable from the same cause, viz., the slimy, pulpy nature of the insect, whilst salt makes their execution even more repulsive. Therefore, taking a good pinch of lime, I buried Mister Slug in that, and seating myself comfortably on an inverted flower-pot watched the effect, little dreaming of what was to follow, never having either read or heard of it.

From the slug's movements I imagined that he was both astonished and offended at the warm reception which he so suddenly met with; still he evinced not the slightest symptoms of dissolution; on the contrary, he set himself to work in a thoroughly business-like manner to extricate himself from his difficulties. In about five minutes I observed the slug's nose appear above the heap of lime in which he lay; but it was perfectly clean and free from the slightest speck. I thought this strange, and I now sat watching the creature attentively. In a little time the whole of the head together with the horns emerged bright and perfectly free from the slightest trace of lime.

My interest being aroused by a phenomenon quite new to me, I examined the creature very closely, and discovered a fold of skin like a cravat round its neck, while the movements of the insect showed that it was gradually divesting itself of its outer skin. The operation was slow, but perfectly systematic; each muscular action increased the thickness of the fold, consequently releasing the body further from its imprisonment; and in about twenty minutes from the commencement the creature had shuffled off its sluggish coil, and was carefully picking its way over the lime in a bran new suit without a speck of the destructive lime adhering to it.

Again I covered my slug with lime and watched the effect; but the task of casting a second skin was too much for it, yet it succeeded in getting its head clear of the lime, and there its efforts failed; it could get no further, and I am almost ashamed to say that I gave the brave fellow no further opportunity.

A. Akerman.

The Importance of Mulching.—Here, in Suffolk, drought is an annual occurrence; nevertheless we do not feel the evil effects of drought so much as is experienced in those counties in which the annual rainfall is usually much greater, and for this reason—we provide as far as possible against it by mulching heavily everything that can possibly be treated in that way, watering being in some seasons a hopeless task. In the first place, we have discontinued digging or forking amongst Gooseberries, Currants, Raspberries, and dwarf fruit trees, and in place thereof, as soon as the winter pruning is completed, we apply a good dressing of old hotbed or farmyard manure at least 3 in. thick and more if possible, spreading it evenly over the surface. All outside Vine borders get a heavy dressing of pig or cow manure. Strawberry beds, too, are heavily dressed early in winter with partly decayed manure, which not only protects the crowns from injury by frost, but stimulates growth when required. The beds are likewise again mulched with stable litter when the Strawberries are coming into flower, and the mulching protects the roots from drought, and after being washed by rain keeps the fruit clean and dry. All wall fruit trees receive a mulching 4 ft. wide, measuring from the wall, as soon as the fruit is set; and in the case of Peaches, Nectarines, and Apricots this is extended according to the season, using as mulching any thing that will break the sun's rays and retain moisture. As regards vegetables, we have annually continued to extend the practice of mulching until more manure is used in this manner than is dug into the soil. Peas being an important crop, we sow all mid-season and late ones in trenches, prepared as for Celery, with good rotten manure dug into them, and as soon as the Peas are up and staked, we fill the sides of the trench full of partly decayed manure, when one thorough soaking of water will keep them in a growing condition for a considerable period, however hot and dry the season may be. All summer and autumn Cauliflowers, French Beans, Scarlet Runners, and other crops are treated in a similar manner, which greatly reduces the number of applicants for the watering-pot, and allows salad and other dwarf plants, that cannot conveniently be mulched, to have more effectual and unremitting attention. From the flower garden we might as well discard Verbenas, Calceolarias, and similar moisture-loving subjects as attempt to grow them without mulching; but by doing this effectually early in the season, and getting the beds thoroughly covered with foliage, the drought has no effect on them. When water is applied, we give as much as will soak away two and sometimes three days in succession, as I regard surface-watering as worse than useless.—J.

BULBOUS PLANTS NOT GENERALLY GROWN.

Ixias, &c.—These, when grown under glass, bloom in March and April. When cultivated out-of-doors they flower from May to July. Morphixias, Sparaxis, Tritonias, and Babianas are allied to the Ixia and require the same treatment, but differ in habit of growth. The Ixia is distinguished by its graceful habit, the Sparaxis by its dazzling brilliant flowers, the Tritonia by its soft vivid transparent colours, and the Babiana by its characteristic foliage, its flowers ranging in

Ixia, a bulbous plant suitable for greenhouse or outdoor culture.

colour from blue to the richest crimson. For in-doors, plant from September to December five or six bulbs in a 5-in. pot, using a compost of turfy loam, leaf soil, and silver sand. Make the soil firm about the bulbs, then place the pots in a cold pit or frame, plunging them in ashes, and withhold water till the plants appear, then give sparingly at first. The lights should be left off except during wet or frosty weather. Early in February if the plants are sufficiently advanced remove to the greenhouse, or where there is a very gentle warmth, and place the pots on a shelf close to the glass, and attend to the plants with water till in bloom. For out-doors, choose, if possible, a light loamy soil, thoroughly drained, and with a due south aspect; if backed by a wall or greenhouse all the better. Plant the bulbs from September to January, at a depth of from 3 in. to 4 in., and 1 in. to 3 in. apart. As the early plantings made foliage during the autumn, it is necessary to give protection during severe frost, and this may be best accomplished by hooping the beds over and covering when necessary with mats; or if tiffany is used it may be allowed to remain till the danger of severe frosts has ceased. The plantings made in December and January require no protection in winter, but as they will flower later in the summer than the early plantings, an aspect should be selected where the sun's rays will be somewhat broken; attention to this will prolong the blooming period. On stiff soil, or soils which lay rather wet in winter, the beds should be raised, and

the bulbs surrounded with sand, taking care that they are planted 1 in. or 2 in. above the level of the path, and where protection cannot conveniently be given, planting should not be made till December or January.

Cyclobothras and Calochortus.—These are remarkably showy plants related to each other, requiring to be planted in light well-drained soil in a sheltered situation, or they may be grown in pots for the greenhouse in the same way as Ixias.

Persian Fritillary (Fritillaria persica).—The accompanying illustration represents a hardy bulbous plant closely related to the Crown Imperial and the British Snake's-head (F. Meleagris). It is a stately plant, well worth culture where a free sandy soil exists. Its flowers, which are borne in long trusses, are of a purple and brown colour. All the above should, according to Messrs. Carter & Co., who grow them successfully, be planted during the next month where the conditions are favourable.

Sweet Peas.—I saw the other day at Heckfield a long line of Sweet Peas, 9 ft. in height and full of flower. The colours of the flowers were many, and all beautiful and all sweet with perfume. To any one who may desire to make a little during the summer by the sale of cut flowers, such a row as this was would be a mine of wealth. Hundreds of nosegays might have been taken from it. To secure such a grand display of Sweet Peas as this was it is necessary to have the soil deep and well manured, the seed sown as early as the middle of March, and some tall sticks. These are dear and difficult to obtain near towns, but in the rural districts are plentiful enough. To prolong the blooming of these Sweet Peas, presently the heads or tops will be cut off, and then the plants will throw out side shoots, and these again will produce an abundance of flowers. In another garden I remarked a pretty effect produced by the sowing together of seed of Sweet Peas and Convolvulus minor, the plants of the latter in this case growing to a height of 3 ft., and blooming profusely. The effect was charming. To get a really grand row of flowers in variety, it is an excellent plan to sow thinly in one drill seed of Sweet Peas, Canary Creeper, crimson and scarlet climbing Tropæolums, and Convolvulus major. It is a floral jumble, and almost a jungle, but the mass of colour obtained in such beautiful variety is really beyond description. The place for such a tall row of colour is where it is perhaps advisable to create a floral screen for the summer. In supporting this mass of growth Pea sticks should first be employed, and these again supported with tall Bean sticks, to the tops of which the Tropæolums will readily ascend. The best Tropæolums are Perfection (crimson scarlet) and Octoroon (deep maroon-crimson); and to check over-luxuriance on their part, cuttings make more suitable plants than from seed.—A. D.

Wintering the Blue Sage (Salvia patens).—So little trouble is involved in taking up and storing away the roots of this Salvia and other plants of a similar character, that it is unwise to risk them out-of-doors, and the superior manner and long period during which it, and other plants of a like nature, will flower when taken up and divided, so as to confine them to fewer shoots than when left in an undisturbed mass, with the opportunity given for fully incorporating manure with the soil, render their being taken up in the autumn preferable in every way to risking their destruction in the open ground.—T.

Planting Hardy Bulbs.—November is generally recommended as the best month in which to plant out-of-door bulbs; but if any one takes the trouble to lift a few bulbs at that period that have been left in the ground, they will find a good quantity of roots and the top growth considerably advanced, clearly showing that November is too late, as a rule, for planting.—J. G.

Fuchsias Out-of-doors.—Although the Fuchsia has been long grown well under glass, its merits as a hardy plant are by no means fully recognised, for the best specimens of out-door Fuchsias ordinarily seen consist of the very oldest varieties. Riccartoni, the old ripened wood of which is hardy enough to withstan ordinary winters, makes quite a beautiful bush in mild districts, but most of the newer kinds do best cut down close to the ground early in winter, and with a covering of coal ashes placed on their roots. Thus treated, such sorts as the white corolla'd Madame Cornellisson, and any free flowering sorts of good habit like Rose of Castile, make most beautiful and continuous-flowering border plants. They need scarcely any attention after they are once planted, as the annual shoots look better left to grow as they like than when a forest of sticks and ties is added under the impression of improving them. The latter give them by far too formal an appearance.—J. H. S.

Creepers for Training over Cottage Doors and Windows.—It is a simple matter the planting a Honeysuckle, Clematis, or Jessamine beside a cottage doorway, or the placing of a potful of earth on the window-sill outside, and sowing a few seeds of the Canary Creeper or Convolvulus in it; and yet what a large amount of pleasure it is capable of affording, not only to the actual possessors, but to passers-by—indeed, from my point of view, the latter is one of the greatest benefits it confers. Example is better than precept, and the lesson taught by a chastely decorated cottage front is carried home to many hearts. Some time ago I was passing a cottage that gave evidence that more than ordinary pains had been taken in ornamenting its doorways and windows with living plants. Over the doorway were trained Clematis Jackmani and C. flammula, mixed and blended together; and as the former became thin of flowers the latter opened its numerous small white sweet blossoms, which scented the atmosphere round. Round the windows were trained Canary Creepers and blue Convolvulus mixed, planted in boxes, which were also furnished in addition with Mignonette. I waited a few minutes beside the house to see what notice was taken of it by the people passing, and the effect was magical; not a single face but wore a pleased look as the eyes glanced upward and took in the view. And, after all, the trouble and expense was a mere nothing; at the most, two or three shillings would buy all the necessary requisites to begin with, and many a man spends that or more in a single week without deriving the least benefit from it in any sense.—H. D.

Protecting Tall Chrysanthemums in Windy Weather.—The situation in which we place our pot plants is sheltered by walls on the north and south, and by hothouses on the east and west, but it is otherwise fully exposed to sun and air. The plants are arranged in lines across the plot of ground, and a strong stake is driven down at either end of the line; cords are then run between the stakes at from 1 ft. to 2 ft. apart, and made fast at each end. The base of the stem is made quite fast to the bottom cord, but as the extremity of the shoot is approached the ties are made gradually looser, the last one, which is within 2 ft. of the extremity of the shoot, having 1 in. or 2 in. of play. The consequence is, that in windy weather the whole mass moves to and fro with the wind with little or no breakage; whereas, before this plan was adopted, though to every stem there was a stake, a sharp gust of wind used to break the tops off the shoots where they were made fast to the stakes. No plan is so safe as leaving plenty of space for vibration, whether upright stakes be used or not.—W. H.

Tufted Saxifrage (Saxifraga cæspitosa).—Amongst plants used for carpeting beds and borders of tall hardy plants I find none so effective as this Saxifrage. Its freshness of verdure, evenness of growth, and general adaptability for that purpose are certainly not equalled by such plants as Mentha Pulegium, which takes a good deal of trimming in order to keep it within bounds; neither is the Herniaria glabra so soft and pleasing as the Saxifrage in question, and, having fully tested it on a large scale, I can strongly recommend it as a hardy plant, which will give every satisfaction in pattern arrangements with the least possible trouble.—G. W.

Snapdragons (Antirrhinums) **in Poor Soils.**—On a piece of extremely poor sandy soil, lying so high that most plants seemed to perish from want of moisture, I have noticed a fine display of Antirrhinums. They seem, indeed, to revel in a situation which is fatal to almost everything else. If the value of this plant for such situations as that just described were better known, it would be more extensively grown. There are places which tax the skill of the cultivator to furnish satisfactorily. On poor, stony, parched spots the Antirrhinum may be planted, and will give good results with but little trouble.—J. C.

Golden-rayed Lily (Lilium auratum) **in Lancashire.**—It is only four years since I managed to summon up courage to plant Lilium auratum out-of-doors, L. candidum and L. tigrinum being the only sorts previously tried in this part of Lancashire. We purchase a quantity of L. auratum annually, and we treat them as follows: When the bulbs arrive they are examined, and arranged according to their sizes, the largest being set aside for pot work and marked for that purpose; they are potted in from 5-in. to 7-in. pots, according to the size of the bulb. The pots are clean washed, carefully crocked, and a layer of Moss, with the green side downwards, is placed over the potsherds. The material used for potting is a really good turfy loam, in a mellow state, without any further mixture, except it be a dash of yellow sand. In potting, the soil is made firm under the base of the bulb, and a thin layer of sand is laid under and around it to prevent rotting. The pots are then filled with soil to the required depth, and the operation is complete. The bulbs intended for planting out are treated in exactly the same way, except that the pots used are a size smaller. All are then taken to a cold pit or frame, and laid on a thoroughly porous bottom of cinders, and covered over with sand to about 2 in. or so above the crown of the bulb; no further notice is taken of them till the young shoots push through the sand in spring. I ought to have mentioned that in potting the bulbs intended to be grown on, it would be better to leave space for 1 in. or so of top-dressing, to be laid over the young roots as they are produced at the junction of the stem with the crown of the bulb. This precaution will not be necessary in the case of bulbs for planting out, as they may remain covered with the sand till planting time, when they should be planted sufficiently deep to admit of the surface roots being covered to 1 in. in depth with rich soil, and afterwards surface-mulched with rough leaf-mould or some similar material. Having thus far described our mode of treatment, it would be well to

point out the importance of aspect, rich soil, and thorough drainage where the rainfall in winter and early spring is heavy, as it is in Lancashire. I am of opinion that the day is not far distant when we shall see preparation made for planting whole beds of L. auratum. Why should we not expend the same labour and expense on the cultivation of some of those choice Lilies as we do in the case of Gladioli, for instance? As to position, it would be well to impress on intending planters the desirability of choosing warm situations, sheltered from biting winds and from the fierce rays of the sun, which soon denudes the stems of half their foliage. I have planted bulbs in shrubbery borders under various conditions and circumstances, and I have been struck with the comparative results in each case. Where the conditions are more or less favourable to the general development of the bulbs, extremes either of drought or of wet will blight even the brightest prospects. I have counted from twelve to nineteen flowers on a single spike from bulbs planted three years ago, and in each case, where the best results are observable, the bulbs are situated in borders facing the south, with the sun's rays broken up into gentle beams by intervening trees and shrubs. The borders, too, are always in good condition, from the fact of their formation being such that they will not retain stagnant moisture, and the shade referred to shields them from excessive heat. I have noticed during the hottest part of the summer how the stems of Lilium auratum shed their leaves even on a north aspect, and how they seem to recover themselves after the intense heat has abated. All these facts are suggestive, and serve to indicate to us certain standard rules, which seem to be of paramount importance in Lily culture.—W. H.

TREES AND SHRUBS.

HARDY CLIMBERS FOR WINTER ADORNMENT.

As the present is the best time for planting evergreens and climbers, the following hints as to subjects may be of service. In most gardens there are positions where it is desirable to produce as cheerful an appearance as possible during winter, and where climbers, either on walls, arches, or trellis-work, may be made a conspicuous feature. Some dislike Ivy on buildings; but even where such a prejudice exists there can be no objection to its employment for covering arches or rustic work of any kind; and as there are now so many beautiful varieties of Ivy, a more extended use of it would add to the appearance of many gardens. Among fruit or berry-bearing wall plants, scarcely anything has a brighter or better effect than the scarlet-fruited evergreen Thorn (Cratægus pyracantha). Though not so fast-growing as some plants, when once a wall is covered with it, if the pruning and training be judiciously managed, it has a rich and striking effect in winter. I saw the other day in a neighbouring village a good-sized house, the front of which was completely covered with it, and the bright berries were set so thickly amongst the dark foliage as to arrest attention.

Cotoneaster microphylla may be used as a wall plant under similar conditions, and it is very effective, both when in flower and afterwards, when the numerous small scarlet berries are ripe. It grows freely in good soil. It is with regret, however, that I plant it where I know rigidity of training is required, as its habit of growth, when left to itself, is so elegant and graceful, as to clearly indicate that it is a plant better suited for the rockery or semi-wild scenery than for a position where every spray must be orderly and circumspect. There are several winter-flowering deciduous shrubs that are indispensable where bright, cheerful effects are desired, and foremost among these must be placed

Jasminun nudiflorum, which in winter is loaded with bright golden blossoms. One almost wishes that it had the sweetness of the common Jasmine, but it is quite scentless. For covering any wall up to 12 ft. or 14 ft. it is most suitable, but I have never seen it growing above that height. I have it against a wall 30 ft. high, but it seems to stop when about half-way up, and makes but little upward growth afterwards. A later blooming yellow-flowered companion may be had in

Forsythia viridissima.—It is even more hardy, free growing, and vigorous than the Jasmine just referred to; and both, if growing on a wall, should be pruned back moderately as soon as the blooming is over, as they flower principally on the young shoots made in summer, and by cutting pretty well back, a large number of elegant graceful sprays of moderate length are always obtained.

The Japan Allspice (Chimonanthus fragrans) is quite indispensable in a collection of winter decorative hardy wall plants. Its flowers, which are freely produced from the time the leaves fall till well on through the winter, are deliciously scented. A small handful of the leafless flowering sprays will give fragrance to a large room. It is a free-growing shrub, and should have the shelter of a wall to preserve and protect its blossoms. There is a large-flowered variety of it too which is even better than the type.

Berberis Darwini should be planted wherever a good winter flower shrub is desired, as both foliage, wood, and flowers are so glossy and bright. It submits readily to training, and grows freely enough in good soil. When well established, it flowers profusely and almost continuously in winter. B. stenophylla is a free-growing, beautiful hybrid, not quite so erect in growth as Darwini; in this respect it partakes rather more of the character of its other parent, B. empetrifolia. It is a very desirable and handsome variety, either for a wall or for any other position. I have occasionally used the common evergreen Barberry (B. aquifolium) for covering low walls, and very effective it is for walls not more than 3 ft. or 4 ft. high.

Escallonia macrantha is one of the best and handsomest late-flowering evergreens, of comparatively recent introduction; or rather, I should say, if it is not new, it is far from being as common as it deserves to be. It is well suited for a wall where only choice subjects are admitted. In sheltered positions it will flower during the greater part of the winter.

Kerria japonica I saw years ago brightening up many a cottage porch and front in Worcestershire in early spring, and its yellow rosette-shaped flowers are pretty and cheerful on low walls. Its height does not under ordinary circumstances exceed 6 ft. or 7 ft.

Lardizabala biternata, although reputedly tender, should be tried in all sheltered situations where variety is sought, as it is very distinct both in foliage, flower, and habit of growth. It would in most cases be advisable to protect it a little in severe weather for the first year or two till well established, as afterwards cold would have less effect upon it. Several of the

Loniceras, or Honeysuckles, should be added to the list, including L. fragrantissima and grata; indeed, a wall wholly planted with different kinds of Honeysuckle would be highly interesting. There are many plants well adapted for low walls that would not be suitable for loftier positions, notably

Pyrus (Cydonia) **japonica** and its white variety; and, in point of fact, almost all of our flowering shrubs, both evergreen and deciduous, may be so employed if desired.

In sheltered positions Laurustinus will flower nearly all winter, and there are few shrubs brighter or more effective for walls not exceeding 10 ft. in height. I have seen Coronilla glauca growing freely on a low wall in Norfolk; and the early flowers of Magnolia purpurea, when trained against a wall, are very beautiful. Where an unsightly wall has to be hidden without breaking up the formal outline, a row of Cupressus Lawsoniana planted quite closely at the bottom of it, and about 18 in. apart, will soon produce an elegant wall of living green. All strong branches must be tied to the wall, and the small twigs cut back with a sharp knife.

E. H.

FRUIT.

Victoria Plum.—This is not a first-class dessert Plum, but selected, well-ripened fruit are very good eating nevertheless, and, being a freestone sort, it is all the pleasanter. As a culinary Plum it stands high, and it makes a delicious preserve. I have often purchased here a fine sample at 7s. per bushel, the selling market price. A strike costing 2s. 6d. gave, when stoned, 15 lb. of good flesh for boiling, which was just 2d. per lb. I may add that a strike is about 3 gallons or one-third of a bushel. It is a common fruit measure in the London market.—A., *Hounslow.*

Warner's King and Devonshire Queen Apples.—One of the finest Apples in the orchards here is Warner's King. It is first-rate as a culinary Apple and for market purposes. The tree is a strong grower and a good bearer. Devonshire Queen Apple is also a useful kind. Being large and having a deep red skin, it makes a handsome dessert Apple for this month and October.—*Exeter.*

Gathering Early Pears.—Although it is not advisable to gather late-keeping Pears a day sooner than the inclemency of the season compels us to shelter them, it is quite different in the case of early kinds, such as Williams' Bon Chrétien, Citron des Carmes, &c. These are much improved by being gathered a week or a fortnight before they are required for use and ripened in the fruit room. This early gathering is also a means of lengthening the season of such kinds as are but a very short period fit for dessert if left to ripen on the trees.

The Morello Cherry.—This should be freely planted where fruit for culinary or confectionery purposes is in request. If planted against a north wall it is one of the most certain cropping fruit trees that we possess; in fact, it should occupy a north aspect for several reasons, but more especially because the blossoming season is retarded in spring, and

because it offers great facilities for preserving the fruit in a fresh, plump condition late in autumn. The fan system of training is that best adapted to the Morello, as it offers the greatest facilities for keeping all parts of the tree stocked with young bearing wood; for, although like the Peach, Morellos will bear on spurs, I find that the young annual growths produce the finest fruits. This is a good time for selecting healthy young trained trees worked on the Mahaleb stock. Having well prepared a good position for them, carefully remove them as soon as the leaves have fallen. Do not overcrowd the wood, and keep it free from fly by means of the garden engine.—J. G.

THE COMING WEEK'S WORK.

Extracts from a Garden Diary.

September 13.—Sowing a large bed of Radishes close to a south wall; shifting some Schizanthus into 3-in. pots; placing pots of Lilium auratum in the sun to ripen the bulbs after flowering; moving Azaleas under cover; making up failures among Endive; nailing Apricot trees; syringing Azaleas for thrips with soft soap, 6 oz. to a large potful of water; looking after thrips on Peach trees and syringing with Quassia chips and soft soap water; getting all Onions into loft and spreading them out thinly; digging ground for Cabbages; earthing up some late planted Broccoli, &c., giving Cucumbers a little top-dressing; hoeing amongst Spinach, Lettuce, Stocks, and Wallflowers, also among autumn-sown Onions.

Sept. 14.—Potting Pinks and Carnations; putting cuttings of Calceolarias into a cold pit; also some Hollyhock cuttings in single pots and placing them in heat, scarcely giving them any water, but leaving on a little air night and day; planting Cabbage, early sorts in rows 6 in. apart; tying up Chrysanthemums, also standard Heliotropes; gathering Irish Peach and Kerry Pippin Apples.

Sept. 15.—Potting Flower of Day Pelargoniums that were struck in pans; re-arranging the greenhouse and potting up a few plants of Alyssum for cuttings in spring; shifting tree Mignonette into larger pots; putting in cuttings of Verbena and Gazania; also more Pelargonium cuttings, consisting of Mrs. Pollock, Christine, and Beauty, into boxes set on flues; taking off Strawberry layers for planting; syringing Vines from which the crop is cut for thrips with soft soap and Tobacco water; watering Spinach with guano water for grub; gathering Ribston Pippin Apples; taking up Garlic, also the most forward Lapstone Kidney Potatoes; spawning and soiling second Mushroom bed; putting soil into a pit in which to plant Tea Roses for button-hole bouquets; thinning Turnips 6 in. apart; removing low boughs which overhang walks.

Sept. 16.—Finishing up Hyacinth potting; re-arranging Fern house; planting spring Cabbages, also Lettuces; pricking out Cauliflowers under hand-glasses and close to walls, also in frames; tying up scented-leaved Pelargoniums ready for conservatory, also Endive to blanch; gathering Apples, also Bergamot and Marie Louise Pears; turning Mushroom manure for another bed; giving Celery a sprinkling of guano and just enough water to wash it in; beginning to earth-up main crop of Celery for first time, also latest Celery.

Sept. 17.—Putting Cinerarias into their flowering pots; potting off some plants of Humea elegans; potting Tulips, also more Roman Hyacinths; potting Narcissi and Intermediate Stocks; putting Mignonette on front shelf in Peach house; shifting latest Balsams; planting Hautbois Strawberries, also Sweet Williams all over pleasure ground by the sides of woodland walks; plunging Disas in Moss, after being potted in very sandy peat; tying up July-sown Lath Cos Lettuce; syringing Violets for spider; gathering some Louise Bonne of Jersey Pears; gathering Lobelia seed; making pits ready for Roses and Violets; top-dressing early Vine border; clipping Yew hedge; cleaning Strawberry plantation.

Sept. 18.—Sowing Nemophila and Saponaria for baskets; potting Guernsey and Belladonna Lilies, also Crocuses and Snowdrops, Iris Susiana, and Her Majesty Narcissus; putting Carnations showing flower under cover; putting Bouvardias into Primula pit to give them a little heat; putting a few cuttings of Christine Pelargonium in boxes, and placing them on Vinery flue; planting out August-sown Cabbages, an operation which should have been done on the 6th inst.; should sow August 5 for this planting in the north of England; netting the best Pears and Peaches; put a skeleton frame over French Beans to carry nets to protect them from morning frosts; gathering all Apples and Pears in orchard except Robins and Greenings.

Glasshouses.

For some weeks after this there is generally a greater scarcity of flowering plants for greenhouse decoration than at any other season of the year, and the difficulty has been considerably increased in recent years when so many fine and distinct flowering plants have been left uncared for in favour of collections of zonal Pelargoniums and others of like character which, although well in their way and very useful where the numbers grown are kept within reasonable limits, yet fail to give the satisfaction that more variety is capable of doing; but if the various plants from time to time recommended have been properly prepared, the early autumn scarcity of flowering subjects can be got over with a fair amount of bloom. Where sufficient numbers are grown of the most distinct habited kinds of tuberous Begonias, especially the narrow-petalled drooping sorts generally so much more profuse in flowering than the erect varieties, they will be found very useful. The latest Lilies of the speciosum section will be also of great service along with Fuchsias treated as recommended earlier in the season, so as to induce them to bloom late.

Lapagerias.—As regards both the red and white kinds of these, although essentially climbing plants and most effective in that way, yet now, when they are becoming more plentiful, there is no way in which they can be made more useful than by growing some in pots, so as to admit of their being moved about to greenhouses or other places when in flower. Whilst they are of medium size they need not be placed on stiff wire trellises in the way in which large examples are grown in pots, but loosely wound round a few erect green painted sticks inserted just within the rims of the pots. In this way they will have a more pleasing appearance, and when they get so large as to require permanent support there is no necessity for training so close and formally on the trellis as is usually done, for when the flowering shoots are left hanging loosely they look much better.

Celosias of the pyramidal section, sown at the time recommended and grown on, will be found most serviceable for conservatories, especially where there is a little heat turned on on cold nights and in damp weather; but whilst here, similar to all other plants in a temperature lower than they absolutely like, they must receive no more water at the root than is necessary to keep them from flagging, for although simply annuals, and injury in this way to them is not of so much consequence as in the case of plants of a more permanent character, yet if treated so as to preserve their roots as long as possible they will continue longer in a presentable condition than they otherwise would do. The same kind of treatment is also applicable to the old Globe Amarantus, another subject equally well adapted for conservatory decoration.

Standard Heliotropes and Habrothamnuses, managed as recommended through the spring and summer, will now take their place in the conservatory, and where a little extra warmth is kept up, later on the Heliotropes will continue to flower almost to the end of the year.

Heaths, the latest autumn flowerers, can likewise be made to do duty in cool conservatories, placing them in the lightest position that can be had, and being careful not to overcrowd them.

Oranges, &c.—Any of these that for a time may have been out-of-doors should now be transferred to the greenhouse. It is in all cases advisable before introducing them to sponge the leaves, and to free them from any insects that may be upon them. Where good gardening is aimed at, this is a matter that at all times require attention, for one foul specimen taken amongst a clean stock will very soon affect the whole, entailing an unlimited amount of extra labour.

Flower Garden.

By way of giving some assistance to the prolongation of the beauty of bedding plants, let dead and decaying flowers and foliage be kept pinched off, and the outlines and groundwork of the various designs should be scrupulously preserved by pinching or pegging, as may be necessary; all the surroundings, too, such as turf, Box edgings, paths, walks, &c., should be kept neat and trim. We may soon expect high winds, and therefore all tall-growing plants should be securely staked and climbers tied in. Remove suckers and straggling shoots from Roses, and see that standards are also securely staked. Any recently budded plants should be examined, and those buds that have fairly started into growth may have the ligatures moved. The propagation of the various kinds of soft-wooded and tender bedding plants ought now to be completed, in order that they may have time to get well established in their pots before cold, damp weather sets in. Offsets of many kinds of succulents can now be had in quantity. All the Sempervivums strike root readily in a cold pit, and in any kind of soil, if not over-watered; a good watering when the cuttings are put in is about all that is required till they have rooted. The commoner varieties, such as S. calcareum and S. montanum, root and winter well on a south border; but till they are rooted and established in the ground they should be netted over, or birds pull them up in their search for insects. The offsets of Echeverias should be afforded the protection of glass where practicable, otherwise they winter tolerably well at the foot of a south wall, particularly if planted on an incline to throw off the rain, which is more fatal to them than frost. Sedums, Saxifrages, and all other hardy dwarf carpeting plants can be increased to any amount by division, an operation which may be done at any time. These latter are all good plants for winter bedding.

Housing Plants.—In the cooler portions of the kingdom it is not safe to leave hard-wooded plants out much longer without there exists some temporary movable protection, such as a canvas convering on rollers, resting on a light wooden framework, than which no more useful appliance exists in a garden, as not only can it be used to keep the plants from drenching rains during the summer, but they will be safe for some weeks yet by running the cover down over them in the evenings when there is an appearance of frost. Where there is not some appliance of this sort they should be got in at once, previous to which the house ought to have had a thorough cleaning. Every plant liable to the attacks of mildew should be examined before being taken in, and where any trace of the parasite is found dust freely with sulphur, for not only can the presence of the mould be much easier detected now than when the plants are arranged, but the chances of its affecting others that are free from it are avoided.

Fruit.

Continue to remove, as opportunity offers, the redundant wood from fruit trees generally. Apricots and Peaches should be kept closely tied or nailed in, and all sub-laterals removed as produced. Some few kinds of Apples and Pears are ready to gather; early kinds are very tender fleshed, and require the greatest care in gathering, as the least bruise soon develops into full decay. For the same reason they should be stored on the fruit room shelves in single layers only. Above all, see that none are gathered prematurely, or they will not ripen, but shrivel, or be sticky and hard. Note should now be taken of all trees that are growing too vigorously, and which will require root pruning, also of any that require assistance to increase root action by the addition of new soil and top dressings, and also of all new planting and plants required for the same, so as to have all in readiness for planting next month—October being the best planting season for all kinds of hardy fruits.

Vegetables.

Potatoes.—Late crops should now at once be taken up, as after this time there is nothing gained by leaving them longer in the ground. Where considerable quantities are grown it often becomes a difficult matter to find room for storing them without resorting to clamping; but, unless where unavoidable, this method of keeping them should never be practised.

Cauliflowers that were sown in the middle of last month will now be ready to prick out, and those intended for early use next spring, and which are to be protected during the winter by handlights, ought to be pricked out in them at once. Double or even treble the number of plants intended to stand may be planted in them and drawn out as growth progresses, and transplanted in other favourable positions as soon as the severity of the winter is past. Of course the covers of the handlights will not be required for use till there is danger of injury from frost. A batch may also be pricked out at the bottom of a south wall and left to stand the winter in that position.

Lettuces.—Make a last sowing in the open air of Lettuces. The Tom Thumb is a beautiful little Cabbage Lettuce for sowing now for frame-work by-and-by. It is very hardy, occupies but little space, and turns in rapidly. The Brown Cos should also be sown now for spring planting. A last sowing of Endive may also be made now on a dry warm border.

ROSES.

ROSE STOCKS FROM CUTTINGS.

The old style of getting up standard Roses by digging up a number of old Briers with long stems from the hedgerows in autumn, and budding them the following season, is still very generally practised; indeed, it has been so long followed that few agree with anything that is said against it; but the system has many weak points that may be improved with advantage. I know a good many Rose growers who object to grow standard Roses on the Brier altogether, because they are so liable to die off or decline in strength. The scarcity of standard Briers is acknowledged: consequently those who are in the habit of grubbing stocks from the hedgerows and elsewhere are compelled to take every Brier that is tall enough and sufficiently thick, no matter what age it is. Briers of this description never have many fibrous roots, and few of them are found without a large club at the end of the stem, which lifts as clear of roots as the head of a walking-stick. How stocks of this kind can support buds and growth until the plants are saleable I cannot imagine; but I can say this, that I have frequently received dozens of standard Roses with club roots as fibreless as the palm of one's hand. Therefore, seeing that fibrous roots are so necessary in order to produce fine Roses and healthy bushes, what wonder that standard Briers should prove so unsatisfactory and die prematurely.

Instead of lifting old rootless Briers do not disturb them at all, but secure all the straight shoots on the Brier bush that can be had, and put them in as cuttings. To insure their rooting they should not be cut, but pulled off with a heel of the old wood attached. When put in in November they are ready for "working" the following July or August. All buds, except two or three at the top, should be removed from each shoot. In putting them in the rows should be 2½ ft. asunder, with 6 in. or 8 in. between each in the row. The cutting should be inserted about 3 in. under ground, and the soil must be pressed very firmly around it. It is an advantage to mulch between the rows after the cuttings have all been put in. Treated in this way, 90 per cent. will root. I am aware that this is not a new way of raising Brier stocks, but it is not practised anything like so extensively as its merits deserve. Stocks thus raised possess all the good qualities of the seedling Brier, as the fine fibrous roots freely produced by the cuttings are equal in every respect to the best produced from seed. And it has this important advantage, that they may be got up from cuttings in half the time which it takes to raise them from seed. The old way of procuring Briers will bear no comparison with the plan now suggested, so far as growth and culture are concerned; and where only one or two Briers could be got from a bush with suitable roots, dozens of suitable shoots can be often had from the same bush. Many grow Roses extensively, using only the cuttings of the Brier, and the plants are healthier and finer grown than any others of the same age. Those who have planted them in previous years are so satisfied with their superiority that they will have no others.—C.

VEGETABLES.

Clubbing-in Broccoli and Cabbages.—I have found the following remedy of the greatest service in cases of clubbing-in Broccoli and other varieties of the Cabbage tribe. Make a mixture of Gishurst Compound and Pooley's Tobacco Powder in a pail of water, adding a little stiff loam to give the mixture some consistency and well puddle the roots with it before planting, after which give the plants another good watering, especially round the collar of the plant. Since the application of this remedy no fresh cases of clubbing have manifested themselves, while several plants which had become clubbed in the seed-bed are now healthy and vigorous.—J. R.

Carrots for Main Crops.—I greatly prefer James's Scarlet Carrot to the longer but coarser varieties so much grown, such as Altringham and Long Surrey. These frequently grow a good way out of the ground, whereby the crown gets discoloured and useless for cooking purposes; James's Scarlet, on the contrary, is usually of fair size, and good in colour and quality.—J.

Mushrooms in Frames.—Mushrooms can be grown successfully in an ordinary garden frame; in fact, it frequently happens that a crop will spring up spontaneously without being spawned or any other preparation after the bed has been used for Cucumbers or Melons; but when intentionally grown in a bed of this description, I have frequently at this season cleared out the exhausted Cucumber and Melon plants, levelled the soil, and inserted a brick or two of spawn in the soil in the usual way; previous to which, if over dry, moistening it moderately with water, allowing a day or two to settle before putting in the spawn, covering with 6 in. of hay. If the thermometer did not indicate a bottom-heat of 75°, I applied back and front moderate linings of warm manure, and covered the glass with 3 in. or 4 in. of litter, tacking down mats to keep it from being blown away. This covering is necessary, as the weather is frequently so bright through this and the beginning of the next month that the heat from the glass, if uncovered, would be too much for the Mushrooms, without admitting air in such quantities during the day as would make the atmosphere too dry. Beds so treated, moistened with tepid water as required, and kept warm by an occasional lining, have continued bearing freely up to the end of November.—B.

Little Pixie Cabbage.—I find this to be an excellent variety for furnishing early supplies. This year, as our autumn-sown plantations were much cut up by the severity of the winter, we sowed under glass early in January Little Pixie, and pricked out the seedlings under temporary shelter as soon as they were large enough to handle, finally planting them out in March in deep drills to shelter them from parching winds. Beyond keeping them frequently hoed in dry weather, they have had no attention, and they are now as fine and even a lot of medium-sized Cabbages as need be seen, and they were fit for cutting before the latest autumn-sown plants or the Early London Colewort, sown on the same day as Little Pixie, and for the majority of cultivators these moderate-sized Cabbages that turn in quickly are preferable to larger varieties that require double the space. We plant 1½ ft. apart each way, and cut them before they get hard and fully grown, as they are much more appreciated than those that are older, the fibre of the leaves in which become hard and stringy, rendering them altogether inferior to the same plants cut as soon as they have acquired a good usable size.—J. G.

Soil and Manure for Cucumbers.—A great depth of soil is unnecessary for Cucumbers; indeed, it is to be avoided, for they will succeed far better if they be planted in a little soil at first and receive frequent top-dressings afterwards; for planting, 8 in. or 10 in. of soil is quite deep enough if the bed receive slight dressings of stable manure mixed with soil to keep the plants in a vigorous state of health. Good turfy loam mixed with rotten manure is the best material in which to plant them, but the dressing should be of a richer nature. Many people use a quantity of peat mixed with the loam for winter Cucumbers; others use leaf-mould, but it is too light; the plants thrive well in it, but do not last so long nor fruit so freely as when grown in more holding soil. Cocoa-nut fibre refuse is highly recommended by some as a good dressing for Cucumber beds, but stable manure is the best kind of surfacing, and may be applied fresh from the stable; and if a little old mortar or brick rubbish be mixed therewith it will be better still. Weak guano water is the best kind of stimulant to apply to Cucumbers; other kinds of manure water are said to affect the flavour of the fruit. I have found a sprinkling of Standen's Manure over the surface of the bed highly beneficial to plants becoming nearly exhausted. Abundance of water is at all times necessary to Cucumber plants growing under advantageous circumstances.

International Potato Exhibition.—We would remind our readers, and especially intending competitors, that the 14th inst. is the last day for making entries for Messrs. Sutton's prizes at the above exhibition, to be held at the Crystal Palace, Sept. 22 and Sept. 23, for eighteen varieties of Potatoes, distinct, nine tubers of each, open to noblemen's and gentlemen's gardeners only. We are glad to observe that the prizes are to be awarded by gentlemen's gardeners. All entries should be made to J. A. McKenzie, Esq., Tower Chambers, Moorgate, London, E.C.

GLASSHOUSES AND FRAMES.

PLANTS FOR VINERIES.

The following is a list of plants that do well with me in a lean-to Vinery, the temperature of which often falls as low as 40° in winter. Under the Vines I have a stand with eight shelves. On the top shelf at the warm end of the Vinery I have four pots of Eucharis amazonica with about twelve bulbs in each pot, but though the foliage is very healthy they have never flowered yet. Next to them is a large plant of Curculigo recurvata, looking the picture of health, and showing several of its insignificant yellow flowers. It is easily reproduced from offsets pulled off and struck in a hotbed. Aspidistra lurida variegata is a very useful plant for winter decoration; I have a large panful of it, and next to it comes a small plant of Cycas revoluta with nine fronds. Then comes a plant of Sanseviera carnea variegata, a highly decorative, though little known plant. Of Palms I have five moderate-sized plants of Latania borbonica and two of Seaforthia elegans, two of Corypha australis, besides two other Palms the names of which I do not know. On the next shelf I have a large handsome plant of Maranta zebrina and a small one of M. regalis, both of which I kept through last winter. Maranta zebrina has now several leaves 10 in. long by 6 in. broad, two shades of green above and violet-purple below. Then come two plants of Dracæna indivisa and five of D. australis; then a large plant of Begonia hydrocotylifolia and another of B. manicata.

I also grow B. sanguinea, B. Weltoniensis, B. fuchsiodes, B. Ingrami, B. nitida, B. erecta grandiflora, B. Grayi, B. discolor, &c., besides about two dozen plants of B. Rex, B. Marshalli, and their varieties, that do well under the stage. I have more than a dozen plants of a Gesnera, which I take to be cinnabarina, and though it does not flower, I find its crimson velvety foliage very effective for winter decoration. I have about a dozen pots of Achimenes and eighteen pots of Gloxinias, which I start in April on a hotbed, and bring into flower in the Vinery. I have two pots of Hoya Bella, which I find does well under the Vines, and a large pot of Plumbago capensis. From the roof I hang plants of Panicum variegatum, Myrsiphyllum asparagoides and Saxifraga sarmentosa, together with the Stag's-horn Fern (Platycerium alcicorne) hanging from the roof. I had Dieffenbachia Baraquiniana and Fittonia argyroneura and Pearcei given to me early in the spring, and although they have done well up to the present time, I am doubtful if I shall be able to keep them through the winter. Coleuses always die when I ripen off the Vines in autumn, so I get a packet of seed for 2s. 6d., and have nice plants all summer. I grow a great many Ferns and some Cacti and Epiphyllums.

Leicestershire.

Cyclamens.—Plants of these that have been grown on freely under glass near the roof, yet guarded from the sun, will usually be found in a much more satisfactory condition—even in the case of old examples—than when exposed in the open air. The second season after sowing they are generally the most useful; but young stock raised from seed sown about a year ago, where well managed, will by this time have made fine bulbs that will bloom well. They will yet require care to keep them free from aphides and red spider, although the latter pest will not from this time cause so much trouble as earlier in the season. If, however, any happen to be present they will yet injure the leaves to an extent that will much interfere with both the appearance and well-being of the plants, as Cyclamens more than most things suffer from the presence of insects. Plants that have been managed on the exposing-in-the-open-air system after flowering, if not already potted

should be attended to in this respect; but it is much better to defer the operation until they have commenced to push up new leaves freely than to pot whilst they are in a comparatively dormant state, as they rarely take freely to the new soil unless the roots are in an active condition at the time of potting, immediately after which they should be placed in frames or pits where growth can be encouraged. A little warmth will be of very great service, for though they may be grown in a temperature such as that which ordinary greenhouse plants require, still there is no question that treatment slightly warmer is more conductive to their well-being, and in the case of young plants they get up to a useful flowering size in much less time.

TULIPS.

THE bulb catalogues which are now arriving remind us that the season for planting and potting Tulips is now at hand; a few hints as to their culture will therefore be seasonable. When grown in pots, Tulips are treated in precisely the same manner as recommended for the Hyacinth in GARDENING last week, but several bulbs, according to their size and the purpose they are intended for, are placed in a pot. Messrs. Sutton & Sons, who grow large quantities of bulbs, remark that when required to fill epergnes and baskets, and other elegant receptacles, it is a good plan to grow Tulips in shallow

Parrot Tulip.

boxes, and transfer them when in flower to the vases and baskets. This mode of procedure ensures exactitude of colouring, height and stage of developement, as the taste of the cultivator may require; whereas, when the bulbs are grown from the first in the ornamental vessels they may not flower with sufficient uniformity to produce a satisfactory display. In common with Hyacinths and Crocus, they may be taken out of the soil in which they have been grown, and the roots washed clean, and inserted in glasses for decorating an apartment. As the early Tulips are extremely cheap, they might often be employed in this way to light up festive gatherings at Christmas and the early months of the year. The first and second classes are admirably adapted for pot culture, but late Tulips are not worth growing in pots because of their lateness; otherwise, indeed, they are extremely beautiful, and the florists varieties are highly valued as exhibition flowers. For general usefulness the Early Tulips are the most valuable of all, because of their peculiarly accommodating nature, their many and brilliant colours, and their suitability for the formation of rich masses in the flower garden. Any good soil will suit them, and they may be planted in quantities under trees, if the position enjoys some amount of sunshine, because they will have finished their growth before leafage of the trees shades them injuriously. If it is necessary to prepare or improve the soil for them, the cultivator must aim at rendering it rich and sandy, and it must be sufficiently well drained that it does not acquire a boggy character in winter. Plant in October or November 4 in. or 5 in. deep, and 6 in. apart. They require no water or supports, and may all be taken up and stored away in good time for planting Geraniums, Verbenas, &c., for the usual summer display. In an extreme case Tulip bulbs may be kept in good condition until the middle of March, and if planted then will flower nicely in May, and be fit to take up in June. We do not, of course, recommend subjecting them to such a trial, but the fact has its value, and many a collection has been saved by the cultivator acting on a knowledge of it. It is important to select the sorts with care for geometric planting, but a most interesting border may be made by planting clumps of all the best sorts of all the several classes. The result will be a long-continued and splendid display, beginning with the Van Thols (which are as hardy as any), then following with the early class in almost endless variety, and finishing with the noble Gesneriana, and the flamed and feathered varieties of the late section. It is not generally known that the Tulips the florists prize so highly make fine border flowers, and may really be well grown with but a tithe of the trouble the florists bestow upon them. The representative of the race is the splendid Gesneriana, with large crimson flowers spotted with black in the centre. The varieties of this section are not adapted for planting in beds that are to be occupied with greenhouse bedders, but they may be taken up in time for the beds to be planted with sub-tropical plants to succeed them, and would be especially valuable for their display of glorious flowers in the month of May, when the flower beds in English gardens are generally quite barren, or but just filled with plants that must have time to make effect.

ANSWERS TO QUERIES.

2908.—**Slugs in Larders.**—The slug referred to is, I presume, the large grey slug frequently found in underground kitchens and cellars, and which, being omnivorous, does good service in consuming scraps of animal and vegetable refuse found in such places. The following is the mode of catching them adopted in gardens, where they are sometimes found in pits or frames, doing damage to young plants and cuttings. Being night feeders, they are very difficult to find in daytime, as on the approach of light they betake themselves to their retreats in crevices, the undersides of stone slabs, or, indeed, anywhere where it is cool and damp and dark. Take some common wheat bran and lay it in little heaps on the shelves or floors where they are known to come, and over each little heap invert a small flower-pot, having stopped the bottom hole with a cork to render it as dark as possible, and tilt the pots on one side, only just leaving room for the slug to crawl in; being fond of bran, he will generally eat his fill of it, and then to be near his supper for the next night, he will usually crawl up the inside of the pot, which being cool and dark will be to his taste exactly. In the morning look over your traps, and any captives may be disposed of by dropping them into a vessel containing a handful of salt.—W. H. ADE.

2916.—**Keeping Flowers in a Cut State.**—The essentials for this are a very cool and perfectly moist atmosphere, with as much light (not sun) as possible. The following plan will be found effectual: Take any old piece of cloth or flannel, and fold it so as to make three or four thicknesses of the size required, and then have ready a bell or propagating glass large enough to hold all the flowers you need to preserve without crushing. Dip the cloth in cold water, and wring moderately dry, and fold it so that the edges come beyond the rim of the bell-glass when turned down upon it. Gather your flowers as early in the morning as possible before the sun has dried the dew off them (if dry when gathered it may be necessary to slightly sprinkle or dip them in cold water). Take your flowers and carefully pack them on the cloth in a heap, and then turn the glass over them. You have now all the conditions for keeping them fresh for several days. The edges of the moist cloth will by evaporation tend to keep the air within both moist and cool. Let them have all the light possible, but avoid the direct rays of the sun. Be careful not to bruise any of the flowers, or the damp atmosphere will soon discolor the part injured, especially of white flowers.—W. H. ADE.

2801.—**Grass going Brown.**—From my own experience, I found that the cause of a large patch of Grass in the middle of my lawn going brown two or three summers was, that there was a small bed of sand about 10 ft. square 6 inches under the surface. I took the turf up, dug out 18 inches deep of the sand, and filled it in with soil and manure; the Grass is now all right. It is a great mistake to cut Grass too short in hot weather.—J. F. H. W.

2893.—**Saving Cabbage Seed.**—Should the Cabbage seed be of a good sort, if ready sow it at once. I had a Defiance Cabbage run to seed this year, and I ripened the seed and sowed it, and am glad to say I have a nice lot of plants for putting out in due time.—W. A.

2896.—**Purchasing Grain &c.**—Flat Maize may pay a good percentage in the course of a month or two, being very cheap now; other grains are likely to be lower yet; round Maize is too dear to speculate in. As regards hay, it will not be dear until about next spring; then it is likely to advance in price.—ONE IN THE TRADE.

2891.—**Pansies in Pots.**—Strike good cuttings in good soil in a cool frame; pot them on in next spring in good decayed cow manure and a little loam; feed them well when growing freely.—PRIZETAKER.

2914.—**Mushrooms Infested with Maggots.**—Your correspondent "Creeping Jenny" will find it very difficult to grow Mushrooms without maggots at this season of the year. I have tried, with some success, covering the bed with ordinary matting. The mischief is done by a small fly with an ovipositor, with which she pierces the young Agaric when not larger than a Mustard seed; she then slips in a few eggs and is off to another young Mushroom. The eggs hatch in a few hours, and the maggots grow rapidly. The great majority of field Mushrooms are infested with maggots, and they chiefly affect the part where the stem joins the cap; here their boring can be seen on breaking off the stem. Nearly all the large old Mushrooms used for making catsup are swarming with maggots.—J. S.

2825.—**Poplar Roots in Lawns.**—This is not a very easy matter. I have known suckers to continue to rise long after the trees were cut down. The best thing to do is to cut the roots well beneath the surface near the points where the suckers rise, so as to permit of their being extracted. To take up the turf and trench over the ground would be more permanent in its effect, but the Poplars will soon send their roots into the fresh-stirred earth again.—E. H.

2824.—**Grape Vines Infested with Red Spider.**—I am afraid, with the main leaves in the condition stated, there is not much chance of colouring the Grapes this year. Fumes of sulphur in a confined atmosphere will destroy red spider, but burning sulphur will destroy all green unripe foliage and wood. The following plan has been tried with success:—Procure two or three lumps of fresh lime, place them in a pail or some open vessel to slake, pouring on sufficient water for that purpose. When the disintegrating process is fairly in operation, take the pail to the Vinery and scatter two or three handfuls of sulphur over the lime and leave it inside. It should be done in the evening, when the house can be shut up close. The pail might be placed under an old chair, or a hand-barrow, or some similar contrivance adapted to break up and scatter the heated column as it ascends. Leave the laterals this year unstopped, as small leaves are better than none.—E. H.

2912.—**Eucalyptus in Winter.**—I cannot give "W. D." much hope of keeping his plants through the winter unless it should prove unusually mild, and for this reason he has brought them from a warm climate into a cold one, and their vitality has been necessarily lowered. As I have been more than ordinarily successful in growing E. globulus, I will give "W. D." the benefit of my experience. Sow the seed in light soil in pots in March, either covering with glass or plunging in a frame. In the autumn plant out in the open ground or transfer into 5-in. pots, which keep out-of-doors. In the latter case the plants must be placed in the situation they are finally to occupy next spring. They can hardly have too much sun or too much water, but they can be too much "molly-coddled." In fact, the whole secret is to let them know at once what they have to expect. By the adoption of this rule I have kept them for five years. One became in that time a tree 25 ft. high, and its stem (a section

of which is before me as I write) a diameter of 7 in. The soil is underlain at 3 ft. by clay, and the aspect south-westerly. No protection whatever was used, nor would any that I could have adopted have availed to save my trees—twelve in all—from the almost Arctic cold of the winter of 1878. I lost them all then, but I have not lost heart in the matter, and am repeating the experiment. One of my last year's seedlings is now 3½ ft. high. I shall be pleased to see the whole subject of Eucalyptus cultivation discussed in GARDENING.

Group of Double Tulips.

Some time since I saw trees of five years at Blidah, in Algeria, which had already attained a height of 60 ft.—H. D., *Dublin.*

—— "W. D." will find the Eucalyptus will not live through a hard winter. I had several that I raised from seed and planted out in a sheltered position in Wimbledon Park in 1876. One grew to over 20 ft., but the winter of 1878-9 killed them completely. A correspondent of the *Standard* stated that the Eucalyptus was cut down last winter at Torquay and Mentone.—T. S.

2829.—**Hibiscus africanus.**—The seeds of the plant usually grow freely when they are new and the soil in a suitable condition. Twenty years ago, when it was commonly used for massing, the self-sown seeds would be in the ground all winter, and make strong vigorous plants in spring. Perhaps "E. G.'s" garden is cold and wet; if so, he should sow in pots or boxes in a frame, or under some shelter, in April, and plant out about the third week in May.—E. H.

2787. — **Pansies Rotting Off.** — When Pansies are seen to be drooping it is well to search for the cause. If, instead of simply pulling them up, the ground about a sickly plant be gently raised with a trowel, the underground stem will probably be found to have some wireworms about it, which should be carefully destroyed. By examining the soil round about, all the offenders may be found and killed, and the injured plant should be thoroughly crushed in order to kill all the vermin that may be upon it.—D. H.

2877.—**Making a Garden.**—The treatment the land has received is right so far, as exposing clay land to the action of the atmosphere tends to improve its character. If some sand, ashes, road scrapings, or burnt earth could be added to the surface and forked in its character would be still further improved; all kinds of manures are also beneficial. If the time can be spared it may be stirred over again this autumn, and should then be left rough till February, when it should be prepared for cropping by forking it over, and by March the land should work well and be in a good condition to receive all kinds of seeds and plants. I am assuming the garden is enclosed with a fence and the walks made, as this should be the first work taken in hand.—E. H.

2888.—**Night-scented Petunia.**—The plant referred to is probably Nycterinia capensis, a half-hardy annual with fragrant, whitish-brown flowers, which expand in the evening. Sow in April in a cold frame, and prick off the seedlings when large enough to handle, placing two in a 4½-in. pot, or the seed may be sown in an open sunny situation in the open ground about the latter end of April. There is another more dwarf species, Selaginoides, very pretty, and which may be treated in the same manner. —J. C. B.

2895.—**Vallota purpurea in Windows.**—Do not disturb your bulbs now; nothing will be gained thereby. Allow them to remain as they are until April, when they may be shifted. This is the season when the flower-spikes should be pushing up, which in any case, however strong the plants might be, they would fail to do were the roots disturbed. It should be remembered that the Vallota requires but little pot room, never blooming freely until the soil is thoroughly packed with fibres. I have plants which have been in the same pots at least four years, and which are flowering freely enough. The young ones may be dibbled in round the edge of a small pot, not pulling them apart when shifting them. A handsome specimen will then be formed.—J. C. B.

2889. — **Early Tomatoes in Greenhouse.**—Take cuttings of Tomatoes now and grow on near the glass, shifting into larger pots as they require it. The points of the shoots 4 in. or 5 in. long, dibbled simply into small pots and kept in a close frame, will soon root; cut near a joint and remove the bottom pair of leaves, using sandy soil. When placed in fruiting pots, which may be 10 in. or 12 in. in diameter, stand the plants on a front shelf and train near the glass.—E. H.

2884.—**Vines in Pots.**—Six-inch pots are too small to fruit Vines in as a rule, but as the Vines in question are seedlings, and no doubt "Enquirer" is anxious to fruit them as soon as possible, I should advise him to let them remain in the 6-in. pots, but to top-dress with rough turfy loam and manure; a good plan would be to plunge the pots into larger ones full of the rough rich compost. If they are not strong enough to fruit next year, then after the buds have broken, rub all off but the bottom one, and grow that on as a single cane, repotting and shifting until they occupy 12-in. pots.—E. H.

2830.—**Propagating Carnations.** — Take layers or cuttings as early as possible in the spring, pot as soon as rooted and grow on, exposing them (plunged in ashes or fibre) in an exposed sunny position during the summer, never allowing a check for want of water, giving the final shift in August. Avoid bringing the plants into the greenhouse till their flowering buds show themselves, as they otherwise get drawn up and weak; but to escape early frosts a cold frame or other protection will be necessary at night. All descriptions of Carnations and Pinks will flower in the winter and spring if treated in this way; but as a rule, the ordinary Carnations will be found more serviceable in April and May, whilst for the depth of winter the Perpetuals are most reliable.—J. A. WALLINGTON.

2879.—**Striking Rose Cuttings.**—A any information will be useful, I will give you my experience. In May, 1879, I made forty cuttings of various Roses, and having filled a long box with earth, I inserted both ends of the cutting into it, so as to form an arch; I then put the box behind the flowers in my conservatory, next the glass, and kept it regularly watered. No change appeared to take place until about the middle of August, when I found they had commenced to come out in leaf, and in about a week from that time they looked quite green. I then tried the experiment of cutting some of them in half, so as to form two cuttings, leaving one end of each in the earth, when I found that the top part of the cutting died off; others I left in an arched state for two or three months, when I cut them in half, and both ends were firmly rooted, neither dying. I did not take them up until the following July (1880), when I transplanted them into pots, where they are thriving well, and will, I hope, bloom next season.—C. W.

2923.—**Roses for Clayey Soil.**—Let me advise "Croft" to consider how many Roses he has space for, to select the best, having regard to variety in colour, giving preference to those on their own roots, to mark out the places and have the clay soil taken out 2 ft. or 3 ft. deep, and if he can procure the cleanings of old ditches which are mixed with decayed vegetable matter with which to fill the holes, I have little doubt his Roses will do well. If not, I would leave the clay soil out all winter to be aërated by frost, and then plant in early spring with the addition of good manure well worked in. My own impression is, that Roses, as a rule, are planted with far too little preparation of the soil to do well. That when the roots can get well down, especially own root Roses, they are quite free from danger from frost, though it is always advisable at first to give a mulching of rough manure or Fern. Planted in the way I have recommended, my own Roses are so healthy and robust as to be little affected by insect pests, and I grow Roses that I should not be afraid to show against our best growers but for my limited quantity. Gloire de Dijon I should think one of the best wall Roses, though it needs special pruning to bloom well. I find that though Roses like moisture, they do not want to be planted in a bog; but I should think too much drainage as bad as too little.—HARTSIDE.

2839.—**Thrips on Orchids.**—In the first place we should inform you that if proper care is exercised, insect plagues will not get such a hold as to necessitate the employment of violent remedial measures. Orchids require constant supervision, searching for and destroying the insect as soon as perceived. Scale is very difficult to eradicate when it has been allowed to obtain firm hold, but perseverance will in time exterminate it. Those who grow Orchids successfully never allow insect pests to get the upper hand, making a point of frequently sponging the foliage, which, whilst benefiting the plants, enables the grower to detect the first appearance of insect life. Solutions of any kind are dangerous in the case of Orchids, the young growths of which are so tender, and are not much favoured by Orchid growers generally.—J. CORNHILL.

2894.—**Plants for Baskets in Winter.** —Tradescantia zebrina is a capital plant for a hanging basket, forming in the course of a season's growth a dense curtain of foliage. Panicum variegatum is a pretty little plant with distinctly marked foliage; and then there is the old but ever beautiful Wandering Jew Saxifrage, one of the very best of subjects for such a purpose, as it will thrive in any situation and is perfectly hardy. A young lady of our acquaintance has made some very pretty hanging baskets, composing them of hardy Ferns and other hardy subjects. The baskets were lined with fresh green Moss gathered from the woods, were then filled with soil, the centre being occupied by a Fern, finishing off with Sedums and Saxifrages, with here a plant of the Wandering Jew and small pieces of variegated Ivy, and the Climbing Toad Flax (Linaria cymbalaria), which were allowed to droop down informally. When established, these baskets presented a fresh and very ornamental appearance, and possessed the advantage of needing but little care to maintain in health.—B.

2799.—**To Keep Rain-water Pure.**—A few words in my answer were mis-read. I said "the bottom an invert, if necessary;" that is to say, if necessary to resist pressure, the bottom should be in the form of an inverted arch; any bricklayer would know what is meant. A pipe to carry the water in and a waste-pipe, of course, are necessary, but not inserted "in the bottom!"—A.B.G.

2843.—**Fruit of Tacsonia mollissima.**—I have never known anybody that cared to eat the fruit of the Tacsonias, although the fruit of Passiflora edulis and the Granadillas are always acceptable. I suppose it is a question of taste; they would not injure anyone that liked them.—E. H.

2834.—**Garden Refuse.**—Mix lime with it, at the same time throwing it into a round heap to ferment; salt and soot may be added with advantage, the former only in small quantities. If fermentation should produce any bad smell, put a layer of dry soil over the heap to prevent the escape of the ammoniacal gases.—E. H.

2844.—**Creeping Jenny.**—The Creeping Jenny is a plant that, as a rule, thrives well anywhere, and is so rarely attacked by enemies, that one reads of your experience with surprise. Your plants are evidently foul and want a good smoking, or to be well sprinkled with Tobacco water. Probably the soil is too stiff, and perhaps sour; also perhaps too wet. The plant is not too choice in its liking for soil which may be fairly good, and including about one-fourth of manure and sharp sand. Perhaps it would be well were you to cut back your plants and re-pot in fresh, good soil; that would no doubt get rid of the blight.

2881.—**Saving Stock Seed.**—The double-flowered plants of Stocks do not produce any seed, but the single plants of the respective kinds only; of these, select the most robust and best coloured and pinch out the points of the flower-spikes, leaving some eight or ten pods on each. These will then ripen fine seed, and a good proportion of double flowers may be looked for next year; but much depends upon the strain. When the seed-pods look brown pull the plants and hang them up till quite dry; then thresh out and put away in small paper bags.

2891.—**Pansies in Pots.**—It is now a good time to put in cuttings of Pansies, the best wood for the purpose being the young growth that comes up so freely from the base of the plants. The cuttings should be put either into a frame or under a hand-light, and in very sharp sandy soil. When rooted, pot up into small pots, and put them into a cool frame on a bed of ashes, and near the glass. Give plenty of air, and protect by covering up from severe frosts. Pinch out the point of the plants to induce side-shoots. Shift again into pots a size larger in March, and yet another shift into larger pots a few weeks later. Keep the plants cool, and give all possible air and light.—A. D.

2878.—**Cocoa-nut for Ornament.**—The Cocoa-nut will not succeed in a greenhouse. It requires a minimum temperature of 55° by night and 60° by day in the winter, also demanding a strong moist heat during the growing season.—C. B.

2837. — **Plants for Aquarium.** — Tradescantia zebrina and Selaginella Kraussiana are two excellent plants for the purpose, as they thrive well in a room. We know of no climbing water plant, but would recommend Valisneria spiralis to be planted at the bottom, and Aponogeton distachyon to float on the surface.—C.

Although the following questions are answered by the Editor, he will be obliged to any of our readers who may think well to answer them according to their experience.

3003.—**Small's Admirable Apple.**—*H. K.*—Scott describes this Apple as follows: "First size; first quality; November to February; roundish, ovate, and flattened; obtusely angular on the sides; skin of an uniform lemon-yellow; stalk long and slender; eye small and closed, set in rather a deep basin; flesh yellowish, firm, crisp, sweet, and agreeably acid, with a delicate perfume; an excellent kitchen and dessert Apple. The tree is an abundant bearer, is of dwarf habit, and well suited for a miniature orchard."

3004.—**Climbers for Arches.** — Please name a quick-growing climber to cover an arch over garden gate, one that would not die down down in winter.—T. WINSKILL. [Honeysuckle, Clematis flammula, and Jasminum officinale.]

3005.—**Harrison's Musk.**—*G. H. P. J.*—This can only be propagated by means of cuttings, which root quickly in light, sandy soil; equal parts loam and leaf-mould, or decomposed manure with a little sand is a good compost in which to grow it. Plenty of water and good drainage are necessary.

3006.—**Drying Gourds.**—*F. G. H.*—Expose them fully to the sun, and when they are hard and ripe cut them and place them under glass where they will get sun and air, but be protected from frost and wet; they may then be hung in a dry loft or room till wanted.

3007.—**Hybridising Melons and Vegetable Marrows.**—*J. H. M.*—It would probably not be a difficult matter to effect a cross between these, but we fail to see what practical purpose it could serve.

3008.—**Wintering Cannas.**—These may be wintered out-of-doors in well-drained soils if 4 in. or 5 in. deep of ashes be placed on their roots. The safest plan, however, is to lift them in October, cut off some of the tops, and store the roots in soil in any place from which frost is excluded. In spring they may be potted and started in a warm frame or greenhouse. The soil through the winter should just be kept from getting dust dry.

3009.—**Lily of the Valley.**—*S. M. P.*—This will succeed in any aspect, but, for choice, one slightly shaded from the mid-day sun is the best.

3010.—**Cocoa-nut Fibre for Flower Beds.**—Would it be a good plan to cover beds of Carnations with Cocoa-nut fibre during the winter as a protection from frost?—FLOS. [Ashes would be better; Cocoa-nut fibre is liable to harbour snails and slugs.]

3011.—**Apricots and Cherry Trees.**—I have a Moorpark Apricot and two Morello Cherries which were transplanted from nursery to walls of my house so late as last April; the former lost its leader through decay. Now, which branch is leader at the present time—the strong one on one side, or the small one which sprung from below where the old leader was cut off? The Cherries have borne an abundance of fruit, and consequently have made little growth, a few shoots only here and there to be nailed to the wall. I should like to know whether I should incite the trees to more growth by the aid of stimulants, and whether any pruning should be done, and how.—W. H. [We do not see that a leader is needed if you train the tree fan-shape, which is the best for all fruit trees on walls, except perhaps Pears. The Morello Cherry will need no pruning this year. It would be unwise to incite the tree to make growth now. You should not have allowed it to bear much fruit the first year, then you would have got growth. Next year, however, you will probably get growth if you mulch the roots with rotten manure early in summer.]

3012.—**Planting Grape Vines.**—Can anybody advise me how to start a Grape Vine, and the best sort? The house in which it is to grow is a small lean-to greenhouse, at present without heating apparatus, facing the south; the soil outside, in which the Vine would be planted, is clay. How deep should it be dug out? and what compost should be put in in which to place the cuttings? and when should it be done?—F. H. R. P. [Dig out the border to a depth of 3 ft., making the bottom to slope to the front; put 6 in. of rough clinkers or old brick rubbish in the bottom; then a layer of sods, grass side downwards; fill up with turfy loam, in which is mixed a liberal quantity of mortar rubbish; also a bushel or so of ½-inch bones if convenient; broken oyster shells may be used instead of bones, if more convenient to get; a liberal supply of horse-droppings may also be mixed with the soil. Procure what Vines you need at once from some good nursery, and plant them as soon as you get them].

3013.—**Propagating Geraniums.**—Having no greenhouse, can I raise Geraniums from slips indoors? if so, how am I to proceed? Is it unhealthy to have a few plants in a bedroom? [Take off strong cuttings 4 in. in length, cut them just below a joint, remove the lower leaves, and insert the cuttings in pots filled half full of drainage, and the other half with sandy soil made firm. Put about eight cuttings in a 4½-in. pot, and place them in the open air in the shade for a week afterwards; expose them to the sun, and house them when cold weather sets in. Water well when put in, and they will probably require no more for at least a fortnight. They will do no harm in a bedroom.]

3014.—**Propagating Double Stocks.**—Will you or some reader kindly say how double Stocks are propagated? I bought some in pots a month ago, and they are flowering beautifully, but they do not seem to be making seed-pods at all like the single Stocks.—A LEARNER. [Double Stocks never seed. If you have any single flowers with five petals save them for seed, and they will probably produce double flowers next year.]

3015.—**Moss on Fruit Trees.**—*Rev. G. G.*—This usually shows that the trees are getting old and worn out, or that the ground is badly drained. The Moss does little harm except harbouring insects. It may be scraped off with a piece of hoop iron, and the trees may be rubbed over with a little lime and water made of the consistency of paint. Thorough drainage is the only effectual cure.

3016.—**Woodlice in Ornamental Tubs and the Garden generally.**—Can anything be done to get rid of them, as they seem only to be affected by boiling water? They spoil the flowers of Pansies and other things which can be kept from slugs and snails in many ways, and are really a worse plague.—A CONSTANT READER. [Plunge small pots on a level with the ground, and fill them with dry hay, and examine daily.]

3017.—**Plants for Back yard in London.**—I have a little back-yard in the neighbourhood of Bedford Row, W.C., with a border of earth in it which I can renovate and fertilise. What plants could I grow there? Would Chrysanthemums do well there in pots? The walls are rather high.—E. R. [Chrysanthemums would do, also Creeping Jenny, London Pride, Virginian Creeper, and the common Jasmine, but few flowering plants would grow well there.]

3018.—**Roses in Clayey or Gravelly Soil.**—*Eve.*—Roses will thrive in clayey soil provided it is well drained and enriched with good stable manure. On gravelly soils there is little hope of success.

3019.—**Veratrum nigrum and Eryngium maritimum.**—*By a Boy.*—The first belongs to the Order Melanthaceæ, and is known as the Black Hellebore; the second belongs to the Order Umbelliferæ, and is known as the Sea Eryngo or Sea Holly.

3020.—**Cattle Eating Trees.**—*E. B.*—The Cupressus would probably not injure the cattle, but the cattle would injure that, and it would therefore be best to keep them off. The Yew is poisonous, and has been the means of killing cattle in many instances.

3021.—**Earthing up Potatoes.**—What valid reason can be given for piling earth against the stems of Potatoes? Of course, it is well to gather about the plant soil sufficient to protect tubers against actual exposure to the sun. This being done, any obstruction to the admission of light and air must surely be unnecessary, if not slowly mischievous.—CUI BONO. [There are several reasons for earthing up Potatoes: Firstly, it admits of a larger surface of soil being exposed to the sun; consequently the soil is warmer. Secondly, it keeps the tubers drier, especially in heavy soils. Thirdly, it induces roots to be emitted from the stems, and consequently increases the crop. Try both ways with the same kinds of Potatoes and on the same soil, and you will then be able to judge by results whether or not earthing is necessary.]

3022.—**Pau Anemones.**—I have received roots of scarlet Anemones from Pau. Can you tell me when I should plant them, and in what soil?—MYRA. [Plant at once in deep, well drained, sandy soil.]

3023.—**Propagating Compact Blue Lobelias.**—*Constant Reader.*—If you cut off the tops of the plants and work a little sandy soil amongst them, they will soon throw up new growth, and you may then dig them up and part them, as they will be found to have made plenty of young roots.

3024.—**Propagating Clove Pinks.**—I have some strong plants of the above I am anxious to propagate, but am not quite sure as to the procedure, and if the present is the best time. They have just finished blooming, and each plant has five or six offshoots around it of this year's growth; these, I think, do not bloom.—HOKEY POKEY. [Layer the offshoots by pegging them down into some fine sandy soil heaped around the plants.. If you slit the stems upwards from a joint with a sharp knife where they are bent down to the soil they will strike much quicker. See illustrated article in GARDENING, July 12, 1879.]

3025.—**Manure for the Garden.**—I have a small villa garden at Balham. It has been my practice for years to throw all garden refuse, about three or four loads, into a heap out of sight, and every autumn to have it emptied into a hole covered with a double frame-light On the top I put sweepings of paths, then some rotten manure, and lastly about one load of the previous year's decayed mould. In this way I have it the third year for garden beds and potting, besides the use of the frame in winter. Can I substitute chemical for horse manure? and if so, about how much per load? and should it be when filling in or when emptying the frame?—E. B. [The horse manure is the best if you can get it. If you use chemical manure, such as Gyde's Imperial Fertiliser, put a good handful to every bushel of soil.]

3026.—**Propagating Alternantheras and Echeverias.**—I should be glad if any correspondent would tell me how to propagate Alternantheras and Echeverias; also if they can be raised from seed.—G. H. [The former will strike readily at this time of the year from cuttings placed in sandy soil in a close frame or pit, and in spring they will give plenty of cuttings, which strike like weeds in a brisk bottom-heat. Echeverias are propagated from offsets which are formed round the bases of the stems of old plants; also from leaves. Seed will give you more trouble than the plants are worth.]

3027.—**Pruning Cucumbers.**—When is the time to cut down a Cucumber plant which has nearly finished fruiting? and how far down should it be cut so as to make it throw out fresh shoots, in order to produce a second crop of Cucumbers?—JENNIE. [Remove all weak shoots and brown leaves, and also remove all blossoms and buds. If the growth is very thick, cut a few of the main stems clean out. Pinch out the growing points of all the remaining shoots. Give the roots a top-dressing of good soil and manure, give a good soaking with water, and keep the frame or house close and moist till new growth commences, then give more air.]

3028.—**Planting Gooseberries, Currants, and Espalier Apple Trees.**—*Amateur.*—Having a good spit-deep of vegetable soil with a sandy subsoil, your ground needs no further preparation for the trees than digging out the holes and working into each a few shovelfuls of thoroughly rotted manure. The ground between the trees can be manured when the trees require it. October is a good time for planting.

3029.—**Mildewed Roses.**—*La France.*—Give the plants a good watering at the roots, and well dust the tops with flour of sulphur through a pepper-box, over the top of which has been tied a piece of muslin.

3030.—**Improving Soil.**—My garden, an old one, and before I got it nine months ago much neglected, is in town, and the soil is poor, stiff, and sour. I have got some good open loam to work into it, and I am told to get leaf-mould. The latter is very expensive here. Is it necessary? I can get either horse or cow manure. Which would you recommend me to use? I have a border for herbaceous plants, and Carnations, Picotees, and Pinks are my hobby; other beds are filled with the ordinary bedding-out stuff, especially Verbenas, which I like. I should add I had the ground well, but not sufficiently manured in the spring with horse manure. The ground is greatly infested with the thin reddish or yellowish worms, which are so injurious to the roots of Carnations. We call them here red worms. Is there any way of getting rid of them except by picking them out?—HORTUS. [In addition to your fresh loam, give the land a good dressing of lime, salt, and soot; also if you can get it, a liberal quantity of road scrapings or old mortar rubbish. Well incorporate these into the soil with a steel fork, digging down at least a good spit deep, loosening up also the bottom of the trench, into which work a liberal supply of horse manure. Leave the surface as rough as possible to allow the frost to get well into the earth. In spring give a good coating of decomposed cow or horse manure, and well fork it in, and you may then commence to put out your plants.]

3031.—**Air-roots on Vines.**—This year I planted a Vine which threw out a great quantity of air-roots, especially at the base. Finding the Vine was not growing rapidly, I put some earth up to these roots to assist it in its growth. I now find the mound completely full of roots. Would it do for me to remove the earth from these roots and cut them off to allow the proper roots to form outside, not inside the greenhouse, as they are now doing?—E. H. MACMAHON. [Remove the soil by degrees, and the roots will dry up and die, when you may cut them off without injury to the Vine.]

3032.—**Temperature for Geraniums in Winter.**—*Douse.*—If the plants are well exposed to the sun before being housed, so as to get their wood well hardened, they will stand a much lower temperature than if their wood is sappy. Damp in winter often causes more damage than frost. In a low temperature the plants must be kept dry at the top, and they will very seldom need water at the root. Keep all decayed leaves picked off, and if the temperature does not go below 36°, the plants may be wintered with success. Of course a higher temperature would be better if it could be given.

3033.—**Removing Grape Vine.**—*Joe Miller.*—As it is a young Vine, you may move it as soon as the leaves have all fallen and you have done what pruning it needs. Or it may be left till early in spring just before it commences growth. Be careful not to injure any of the roots, and plant in good, turfy loam, to which may be added some horse droppings, a little mortar rubbish, and soot. Give a good watering after planting.

3034.—**Geranium Cuttings.**—About ten days ago I had some Geranium cuttings sent me. I put them in a cold frame, and they looked well and strong. Some of them have blossomed; ought I to take the blooms off? I give them plenty of air in the daytime, and close the frame at 5 o'clock.—TOM. [Remove the blossoms as they appear, and expose the plants to air and sun. Leave air on all night till the weather gets cold.]

Dissolving Bones.—*B. K. H.*—See GARDENING, July 24, 1880.

Fungi on Grapes.—*W. D. M.*—Send us specimens.

Fitting up Greenhouses.—*G. B.*—Do you mean a frame? Surely you do not mean a greenhouse only 4 ft. 6 in. long, and 2½ ft. wide? Tell us more about it.

Vegetation Feeding on Animal Life.—*Eniatnuof.*—See GARDENING, August 2, of last year.

Flower-pot Stove.—*H. H.*—GARDENING, October 25, 1879.

Names of Plants.—*Nemo.*—Send piece of the plant with leaves and flowers attached.——*A. N.*—Gooseberries smashed to a pulp; Strawberry White Queen.——*St. R. B.*—1, yellow, a perennial, common Moneywort (Lysimachia vulgaris); 2, Caper Spurge (Euphorbia lathyris); 3, Scabiosa arvense.——*A. S.*—Adiantum cuneatum.——*Joseph Inman.*—The Marsh Cud-weed (Gnaphalium uliginosum).——*Mark.*—1, one of the garden varieties of Tropæolum; 2, the creeping Fig (Ficus repens).——*S. F. P.*—The Fuchsia is evidently a garden variety and not a species, therefore we could not name it with any degree of certainty.——*T. L.*—1, a species of Globe-flower (Trollius); 2, Fuchsia Prince of Orange apparently; 3, Spiræa filipendula.——*E. G.*—The Giant Knotweed (Polygonum cuspidatum).——*G. L.*—1, The British Maiden-hair Fern (Adiantum Capillus-veneris; 2, Adiantum concinnum, we think; 3, Selaginella Browni; 4, Nephrolepis exaltata; 5, Platyloma rotundifolia.——*D. E. F.*—Ranunculus aconitifolius fl.-pl.——*E. G. F.*—Campanula muralis.——*W. H. A.*—1, Solidago (species); 2, Solidago multiradiata; 3, Chenopodium atriplicifolia; 4, Polygonum amphibium.——*Rev. L. A. B.*—Sedum populifolium.—*Cymro.* 1, Jacob's Ladder (Polemonium cœruleum); 2, Veronica spicata; 3, Erythræa littoralis.——*E. P.*—1, Aster linifolius; 2, too much withered; 3, Spiræa Ulmaria variegata; 4, Clematis vitalba; 5, Spiræa ariæfolia; 6, Veronica spicata; 7, Aster pyrenæus; 8, Helenium autumnale; 9, too much withered; 10, Solidago; 11, no flowers; 12, Agapanthus umbellatus variegatus; kindly be a little more moderate next time.

QUERIES.

To Querists.—*All questions are inserted or answered in these columns free of charge, provided the following rules are observed: 1.—Write clearly and concisely on one side of the paper only. 2.—Use a separate sheet of paper for each query. 3.—Give full name and address, with any nom de plume or initials you may wish used in the paper. Questions only of interest to the persons asking them should be accompanied with a post card or stamped addressed envelope for reply.*
